To the Editor of  
Reproduction in Domestic Animals

Valenzano (BA), May 7<sup>th</sup>, 2018

Dear Editor,

please find enclosed the manuscript:

“Ejaculation effect on blood testosterone and prostatic Pulsed-Wave Doppler ultrasound  
in dogs”

by Salvatore ALONGE, Monica MELANDRI, Raffaella LEOCI,  
Giovanni Michele LACALANDRA, and Giulio AIUDI

The paper is submitted to be considered for publication in *Reproduction in Domestic Animals* as a short communication belonging to “ESDAR supplement” for the ESDAR Congress 2018.

The manuscript has been approved by all co-authors and it is has not been published elsewhere.

Correspondence regarding the paper should be directed to the following address:

## SUMMARY

Local vessels ultrasonography evaluates prostatic physio-pathologic states. Testosterone promotes tissue and vascular growth. Knowing variables on prostatic vasculature is crucial to correctly apply Pulsed-Wave exam. The study aims to assess how ejaculation and blood testosterone affect Pulsed-Wave indexes. Serial blood testosterone dosages and Pulsed-Wave exams were performed in 20 dogs, immediately before (T0) and after (T1) ejaculation and 6 hours later (T2). *Arteria prostatica cranialis*, *Arteriola capsularis*, *Arteriola trabecularis* and *Arteriola parenchimalis* were evaluated and mean Pulsatility and Resistivity Index, Systolic-Peak, End-Dyastolic and Mean Velocity calculated. Data were grouped by time and vessel (ANOVA,  $p \leq 0.05$ ). At T1, Resistivity Index significantly lowered in *Arteria prostatica cranialis*, *Arteriola trabecularis* and *Arteriola parenchimalis* but grew in *Arteriola capsularis*; Pulsatility Index had the same pattern, but not significant in *Arteriola parenchimalis*; Systolic Peak Velocity, End-Dyastolic Velocity, Mean Velocity significantly rose in *Arteriola capsularis* and *Arteriola trabecularis*. No indexes differed at T0 and T2. Testosterone did not differ at T0 ( $10.93 \pm 7.05$  ng/ml), T1 ( $12.71 \pm 7.29$ ) and T2 ( $10.54 \pm 6.63$ ). Results stated the risen prostatic vascular flow post ejaculation, affecting Pulsed-Wave. Due to semirigid capsule, impairing vasodilation of other vessels, only *Arteriola capsularis* indexes increased. Intimal cushions of *Arteria prostatica cranialis* kept velocities fixed; *Arteriola capsularis* and *Arteriola trabecularis* lack of intimal cushions, thus velocities grew. In *Arteriola parenchimalis*, pre-capillary sphincters opening allows increased flow redistribution in vasodilated parenchymal bed, keeping velocities fixed. Since testosterone, not affected by ejaculation, did not peak, vascular changes are not due to testosterone itself. These physiological effects of ejaculation suggest proper sexual rest before Pulsed-Wave exam planned to explore suspected prostatic neovascularization.

**Keywords:** dog, prostate, ultrasound, Pulsed-Wave, testosterone.

## 27 INTRODUCTION

28 Ultrasonography is the most important tool to diagnose prostatic disorders (Mantziaras *et al.*, 2017).  
29 Normal and abnormal sonographic findings of the canine prostate have been well investigated  
30 (Russo *et al.*, 2012). However, no pathognomonic images to univocally diagnose any of the  
31 pathologic conditions by B-mode exam exist (Levy *et al.*, 2014). Thus, different Doppler techniques  
32 have been investigated to improve andrological diagnostics: Color, Power and Pulsed-Wave (PW)  
33 have been recently applied to the non-invasive study of local vascularization, to evaluate prostatic  
34 physio-pathological conditions, mainly considering increased blood flow during prostatic diseases  
35 (Günzel-Apel *et al.*, 2001; Freitas *et al.*, 2013; Zelli *et al.*, 2013). To make these techniques  
36 successful, appropriate knowledge of normal prostatic vascularization and deep identification of  
37 physiologic variables possibly affecting it are fundamental (Newell *et al.*, 1998). Modern imaging  
38 techniques necessitate additional names for prostatic arteries branches, resulting from anatomical  
39 microvasculature studies (Stefanov, 2004). *Arteria prostatica cranialis, media* and *caudalis* are  
40 muscle arteries, common blood distributing organic vessels, having intimal cushions (Stefanov,  
41 2004). When reaching the gland, they branch, leaving *Arteriola capsularis*, first-order arterioles,  
42 previously named Subcapsular arteries (Hodson, 1968), that form a single-plane net (Stefanov,  
43 2004) in the semi-rigid prostatic capsule thickness, composed of fibro-elastic tissue (Rhodin, 1974).  
44 Second-order direct arterioles, *Arteriola trabecularis* (Stefanov, 2004) and third-order branched  
45 arterioles, *Arteriola parenchimalis*, first described by ultrasound contrast agent (Hagen *et al.*,  
46 2000), provide parenchimal vascular supply. Testosterone, promoting androgenic-receptor-mediated  
47 tissue growth and stimulating angiogenesis and vascular growth (Franck *et al.*, 1998), must be  
48 considered among parameters possibly affecting prostatic vascularization. Recently, the role of  
49 ejaculation on prostatic vascular appearance on Power Doppler exam was assessed (Alonge *et al.*,  
50 2018) in order not to misdiagnose the prostatic neovascularization occurring during glandular  
51 disorders (Newell *et al.*, 1998; Freitas *et al.*, 2013; Polisca *et al.*, 2013; Zelli *et al.*, 2013). Present

1  
2 52 study aimed to evaluate if and how ejaculation and blood testosterone affect prostatic Pulsed-Wave  
3  
4 53 exam and to state how long this effect lasts.  
5  
6 54

## 7 55 **MATERIALS AND METHODS**

8  
9  
10 56 Twenty different-breed dogs were enrolled (2-5 y.o., 5-42 kg bodyweight), all healthy at physical  
11  
12 57 examination and used to digital manipulation. The study was performed in accordance with animal  
13  
14 58 welfare committee ethical guidelines and all procedures were carried according to the Italian  
15  
16 59 legislation on animal care (DL 116, 27/01/1992; ethical approval n° 35/17 DETO, 26/06/2017).  
17  
18 60 Informed owner consent was obtained. Sexual rest was required for 7 days before examination and  
19  
20  
21 61 during the study.

22  
23 62 Serial PW prostate exams (MyLab™ClassC, Esaote Spa, Genua, Italy). and blood testosterone  
24  
25 63 dosages (ELISA Testosterone, Demeditec Diagnostics GmbH, Kiel, Germany) were performed  
26  
27 64 immediately before (T0) and after (T1) ejaculation, and 6 hours later (T2). In each exam, three PW  
28  
29 65 images of *Arteria prostatica cranialis* (APC), *Arteriola capsularis* (AC), *Arteriola trabecularis*  
30  
31 66 (AT) and *Arteriola parenchimalis* (AP) (Stefanov, 2004), with spectral tracing with three sequential  
32  
33 67 waveforms (Figures 1-2-3-4), were evaluated. Medium values for Pulsatility (PI) and Resistivity  
34  
35 68 (RI) Indexes, Systolic-Peak (SPV), End-Dyastolic (EDV) and Medium (MV) Velocities were  
36  
37 69 calculated. Data were grouped according to time and vessel and statistically analyzed by ANOVA  
38  
39  
40 70 ( $p \leq 0.05$ ).  
41  
42  
43 71

## 44 72 **RESULTS**

45  
46  
47 73 At T1: RI significantly lowered in APC, AT and AP but grew in AC; PI had the same pattern, but  
48  
49 74 not significant in AP; SPV, EDV, and MV significantly rose in AC and AT ( $p \leq 0.05$ ). No indexes  
50  
51 75 differed between T0 and T2. Specific results on PW parameters are reported in Table 1.  
52  
53 76 Testosterone did not differ at T0 (10.93±7.05 ng/ml), T1 (12.71±7.29 ng/ml) and T2 (10.54±6.63  
54  
55 77 ng/ml).

## 78 DISCUSSION

79 Present results agree with previous reports, concerning basal PW exam (Newell *et al.*, 1998;  
80 Günzel-Apel *et al.*, 2001; Freitas *et al.*, 2013; Zelli *et al.*, 2013) as well as blood testosterone before  
81 and after ejaculation (Kobayashi *et al.*, 2013). To the authors' knowledge, PW prostatic parameters  
82 after ejaculation and prostatic vessels MV were never previously evaluated. Moreover, this is the  
83 first description by basal Doppler sonography of *Arteriola trabecularis*, whose flow was previously  
84 identified only by contrast-enhanced ultrasonography (Hagen *et al.*, 2000).

85 The increased vascular prostatic flow is detectable up to 24 hours after ejaculation by Power  
86 Doppler (Alonge *et al.*, 2018), which is very accurate in recognizing slow flows (Zelli *et al.*, 2013).  
87 Pulsed-Wave, more specific for high flows, is instead altered just for 6 hours. It can be inferred that  
88 ejaculation induces a definite increase in prostatic vascular provision, with high flows lasting for 6  
89 hours, detectable by PW, and slow ones keeping on for 24 hours, highlighted by Power Doppler.  
90 Resistivity and Pulsatility Indexes increased only in AC due to semi-rigid capsular histology  
91 (Rhodin, 1974), not allowing vasodilation occurring in other vessels. Intimal cushions of APC  
92 (Stefanov, 2004), the only examined arteria, kept velocities constant. Conversely, AC and AT lack  
93 of intimal cushions, thus velocities increased. Finally, in AP the pre-capillary sphincters opening  
94 (Stefanov, 2004) allows the increased flow to redistribute in the vasodilated parenchymal vascular  
95 bed, keeping velocities constant.

96 Testosterone blood determination along time was not affected by ejaculation, thus vascular changes  
97 are not due to testosterone itself. Further studies should evaluate the role of other hormones, such as  
98 prostaglandins, primarily produced by sexual accessory glands (Kobayashi *et al.*, 2013), on  
99 prostatic ejaculative vascular changes.

100 Pulsed-Wave Doppler is a suitable non-invasive tool available to the clinician to study prostatic  
101 vascularization, fulfilling the morpho-functional evaluation of the organ. Present results indicate  
102 that, irrespective of basal patho-physiologic conditions, ejaculation alters PW appearance of the  
103 prostate. Thus, in conclusion, a proper sexual rest of at least 6 hours should be applied whenever a

1  
2 104 Pulsed-Wave exam is planned for a dog suspected of any prostatic disorders possibly leading to  
3  
4 105 neovascularization.
