Error, Uncertainty, Metrology

Engineering Sciences Section - 2015

D30 Limitations Associated With the Examination and Presentation of Fingerprint Evidence

Melissa Gische, MFS, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the critical decision-making points in the fingerprint comparison process, the types of errors that may occur, the research that tests examiner performance, and the limitations associated with reporting and testimony.

This presentation will impact the forensic science community by highlighting the limitations associated with both the examination and presentation of fingerprint evidence.

The analysis, comparison, and evaluation of latent fingerprints are an interpretive process. Examiners apply the knowledge gained through training and experience, in addition to the current research in the field, to reach a decision when conducting fingerprint examinations. As with any subjective process, human factors can influence the outcome of latent print examinations. This presentation will discuss the steps involved in the latent print examination process, identifying those that are potentially the most susceptible to cognitive biases. Quality assurance measures, such as documentation and verification, may be implemented to minimize the effects of various human factors and reduce variability in the examination process.

During the latent fingerprint comparison process, examiners are assessing the quality and quantity of information in the prints. If this information is misinterpreted, an error may result. Errors may occur during the examination process (false positive or false negative) or during the presentation of evidence in reports or testimony (overstating or understating the value of the conclusion). As such, examiners need to state their opinion and provide the scientific basis to support that decision, while clearly expressing the limitations of the science.

The literature related to error rates emphasizes the difficulty in calculating a meaningful error rate for both individual practitioners, as well as across the entire discipline; but the possibility for error will always exist. Recent studies have demonstrated that while examiners may reach accurate and reliable conclusions, the calculated error rates in those studies are specific to the testing conditions of the studies and may not include all the quality assurance measures of a laboratory or consider other variables inherent to fingerprint examinations.

Three main limitations associated with the reporting of fingerprint opinion conclusions include making identifications to the exclusion of all other sources, providing an absolute or numerical certainty, and stating that the error rate is zero. This presentation will discuss how these concepts are not supported by research and why they should not be used to express conclusions. Instead, examiners must clearly explain the scientific basis for their conclusions while remaining cognizant of the associated limitations.

Fingerprint, Error, Evidence

D31 Certainties and Uncertainties in Accident Reconstruction — How Correcting the Other Side’s Misstatements Affects Jury Verdicts

Peter Alexander, PhD*, 23595 E Irish Place, Aurora, CO 80016

After attending this presentation, attendees will understand uncertainties in accident reconstruction.

This presentation will impact the forensic science community by improving attendees’ understanding of accident reconstruction.

Accident reconstruction involves the examination of the data from an accident (usually a multi-vehicle collision) to determine what happened. Since the state or local police usually provide reconstruction services for the prosecution in criminal cases, the independent accident reconstructionist is often engaged to support the defense. The goals are to provide the defense with an objective understanding of what actually happened and to assess whether the prosecution’s charges are supported by the evidence. The reconstruction addresses such issues as the speed and headings of the vehicles, an analysis of where each vehicle was located both before and after the impact, visibility issues, perception/reaction times, and analysis of any violations of the relevant driving statutes.

Although accident reconstruction can produce surprisingly accurate results, unless the limitations of the analytical methodology used are clearly understood, there can be significant potential errors associated with all the techniques employed. It is prudent to understand these uncertainties to ensure that the other side is not relying on a faulty premise when they claim that the accused was traveling at 100mph just before the collision. This presentation will discuss not only the uncertainties inherent in the physical procedures used to reconstruct accidents but also misinterpretations of the accident parameters to support charges which cannot be sustained.

Uncertainties relating to methods for determining a vehicle’s speed during an accident are described in the table below. Some of these uncertainties can lead to very large errors in the reconstructed speed value.

VEHICLE SPEED DERIVATION METHOD	SOURCE OF UNCERTAINTY
Speed loss from length of skid marks x drag factor	Vehicle travel before braking marks appear Uncertainties in the coefficient of friction value
Black box data	Crash event may not trigger recording Data record may be corrupted Sometimes provides wrong results
Vehicle damage Comparison to staged crash tests Using Numerical Models (CRASH III)	A crash test at the speed needed is not always available Need to convert Vehicle-To-Barrier results to Vehicle-To-Vehicle speeds Models contain many simplifying assumptions and are very inaccurate at onset of crush <u>Stiffness values are highly variable</u>
Momentum conservation calculation	Need accurate approach and departure angles, post-impact travel distances
ANCILLARY INFORMATION Distances from police scene survey Roadway friction Coefficient of restitution	Police laser-scene surveys found to have significant errors Friction values from drag sled and accelerometer measurements are not precise Coefficient of restitution can vary widely

The above discussion involved errors inherent in the physical procedures used to reconstruct accident speeds. A similar discussion could be held regarding vehicle headings and other factors relating to the reconstruction. Sometimes individuals are prosecuted or even convicted based on erroneous interpretations of the accident data.

Engineering Sciences Section - 2015

A number of vehicular homicide criminal case studies will be presented in which the accident data did not support the charges levied by the prosecution. This resulted in a substantial reduction in the charges that were sustained by the jury. Often the accident analysis presented by the prosecution found a speed for the defendant's vehicle which was far above the speed that was reconstructed by the defense. In some cases, the laws of physics were violated in the prosecution's analysis in order to arrive at the claimed vehicle speed. These questionable forensic analysis practices have a pernicious effect on a broad spectrum of the legal system since a civil action frequently follows the criminal prosecution. In that event, the questionable results of the prosecution's reconstruction often find their way into the civil litigation.

Reconstruction, Uncertainties, Verdicts

D32 Forty Years of Squinting — Environmental Forensic Microscopy: 1974–2014

James Millette, PhD, MVA Scientific Consultants, 3300 Breckinridge Boulevard, Ste 400, Duluth, GA 30096*

After attending this presentation, attendees will better understand how different types of microscopes can be used in environmental/industrial investigations.

This presentation will impact the forensic science community by providing illustrations of how environmental forensic microscopy has been used to solve contamination and other questions by one investigator and his team over the past 40 years.

During the first 40 years of my career, I have had the opportunity to use various microscopes and forensic techniques to solve a number of interesting environmental/industrial questions involving product identification, indoor air quality concerns, outdoor darkening agents including various types of soot, lead particles, asbestos, and glass fibers, ceramic whiskers, corrosion debris, and particles from the World Trade Center disaster of September 11, 2001. The sampling and analysis methods I have used over the years in environmental forensic investigations were drawn primarily from the criminal forensics, industrial hygiene, and environmental monitoring areas. Combining various aspects of these disciplines allowed me to generate a procedure that fit the varied and sometimes very complex environmental/industrial situations.

Some investigations required only a light microscope but many of the microscopic analyses in environmental forensic investigations were accomplished utilizing a combination of visible light, infrared light, and electron microscopy. The light microscopy was usually performed initially with a stereo-binocular microscope followed by Polarized Light Microscopy (PLM) but may have involved Phase Contrast (PCM), darkfield, or fluorescence microscopy. Infrared microscopy was done using Fourier Transform Infrared (FTIR) microspectroscopy. FTIR is very useful when identifying organic molecules such as plastics and polymers. Scanning Electron Microscopy (SEM) was used in some studies because it allows the analyst to see particles that are smaller than can be seen with light microscopy and when equipped with an X-ray analysis unit, allows the analyst to determine the elemental composition of the particles. Transmission Electron Microscopy (TEM) also allows the analyst to see particles that are smaller than can be seen with light microscopy and when equipped with electron diffraction capabilities and an X-ray analysis unit, allows the analyst to determine the crystal structure and elemental composition of the particles.

One environmental method, American Society for Testing and Materials (ASTM) Practice D6602, provides a list of different types of microscopes used to investigate particles: a stereo-binocular microscope, capable of 1-60x magnification; a polarized light microscope, equipped with objectives in the 4-100x range of magnification (for a total magnification between 40x and 1000x); a transmission electron microscope equipped with a suitable camera; and a scanning electron microscope equipped with Energy or Wavelength Dispersive Analysis Equipment (EDS or WDS). A TEM equipped with Selected Area Electron Diffraction (SAED) and EDS is sometimes referred to as an Analytical Electron Microscope (AEM).

The capabilities of the various microscopy tools will be illustrated through short presentations of several investigations including: the source of asbestos fibers in a kitchen faucet filter; the composition of many building products studied during a case working for the Attorney General for the State of Maryland; characterization of dust that was generated by the World Trade Center tragedy of September 11, 2001; a spot called Ralph on a carpet in a South Carolina courthouse that kept growing larger; particles in home dust that were reported to be evidence of an alien visitor; and, the sources of black, white, and yellow deposits on automobiles.

Microscopy, Environmental, Historical Uses

Engineering Sciences Section - 2015

D33 Look at the Chemistry

*James S. Smith, PhD**, Trillium, Inc, 28 Graces Drive, Coatesville, PA 19320-1206; and *Carol A. Erikson, MS*, 1433 Yarnell Station Boulevard, Knoxville, TN 37932

After attending this presentation, attendees will better understand the importance of giving even “non-detected” analytical results a closer look.

This presentation will impact the forensic science community by providing attendees with another valuable tool to use during forensic environmental investigations.

Environmental site investigations generally start with investigating the historical uses of the property. This information, along with experience with the background of the site, allows the investigator to design a sampling program to evaluate soil, surface water, ground water, and other materials and matrices as appropriate to the site. Selection of the chemical analyses to be performed on these samples also relies on the historical uses and experience with similar locations, as well as on state and federal lists of chemicals that may have been used and/or abused on the property. For organic chemicals, two primary analytical methods are commonly utilized to test for a large number of compounds. These are United States Environmental Protection Agency (USEPA) SW-846 Method 8260 for volatile organic chemicals and Method 8270 for semivolatile organic chemicals. Combined, these two methods list approximately 400 compounds that may be analyzed; typically, more than 100 target analytes are routinely reported.

After the analyses are completed, the laboratory presents the interested party with the results, which include the “hits” for the specified target analytes. These methods also provide a quantitative value for the concentration of the target analyte hit, which is a single organic chemical. If this concentration is above the applicable state or federal criteria, then there will be more investigation that may lead to site remediation.

There is a “but.” If there are no concentration values above the criteria, then the sample and/or site is determined to be clean. But... is it, really?

A new house was built on a hill. The water well was a major expense because it required drilling over 400 feet into bedrock and piping the water one-quarter of a mile to the house. The water smelled like paint thinner, caused the plastic pipe to soften, and readily passed through carbon treatment tanks. Yet, the analytical chemistry using Method 8260 did not give a single target analyte “hit;” however, once the full supporting data package was acquired, it was readily apparent from the total ion chromatogram that the groundwater sample was loaded with gasoline hydrocarbons. The groundwater had “weathered” the gasoline by removing the aromatic compounds associated with gasoline that were on the target analyte list, so the reported analysis results were all “non-detects.” BUT — plenty of gasoline leftovers were still in the groundwater entering this well.

Who would have guessed that farm land would be contaminated? Maybe the hydrocarbon transmission pipeline running in front of the house should have been a clue?

Chemistry, Target Analytes, Non-Detects

Engineering Sciences Section - 2015

D34 Let's Leave the Junk in the Junk Yard

Michael C. Hadka, PhD*, 520 Peck Road, Downingtown, PA 19335; and James S. Smith, PhD, Trillium, Inc, 28 Graces Drive, Coatesville, PA 19320-1206

After attending this presentation, attendees will be able to recognize that junk science exists in environmental forensic science and where it is often found.

This presentation will impact the forensic science community by increasing awareness of the fact that age-dating contaminant releases is often misused in environmental forensic science and some of the common misunderstandings that often turn into junk science.

One of the first questions often asked in environmental litigation concerning the release of a contaminant into the environment is, When was it released? The answer to this question is important in determining responsibility and liability for the release, particularly when there was a series of owners or operators of the facility. Determining when a contaminant was released is often referred to as "age-dating." The literature contains numerous proposed procedures for estimating the timing of a release. Too often these procedures are used by so-called "experts" as a stand-alone magic formula to age-date the release and they ignore the science behind the procedure.

A case in point is estimating the age of the released gasoline product samples using the toluene-to-n-octane (T8) ratio technique by Schmidt, et al.¹ The T8 procedure is based on the increasing enrichment of aromatics in gasoline in the 1970s and the reduction of n-alkanes in gasoline beginning in the 1980s. Schmidt, et al. examined gas chromatograms of 130 regular and mid-grade gasolines produced between 1973 and 2001 and graphed the T8 ratios versus the year of production. The T8 ratios fell into three groups: T8 less than 5 was the 1973 to 1983 group, T8 between 5 and 10 was the 1984 and 1993 group, and T8 greater than 10 was the 1984 to 2001 group. In one recent case involving gasoline contamination from an underground storage tank, the consultant said the gasoline was released between 1994 and 1993 based on the T8 ratio; however, the consultant used the results from a groundwater sample collected from a monitoring well. In doing so, the consultant ignored basic chemistry, including solubilities and Raoult's Law in comparing groundwater results to that of dispensed gasoline. The equilibrium solubility of toluene in water is more than 700 times greater than that of n-octane at 20°C. This is akin to the idiom "comparing apples to oranges." In addition, the consultant also ignored the effect of biodegradation, volatilization from the groundwater, and transport (including sorption and retardation) differences that will create changes in the ratio between toluene and n-octane dissolved in groundwater, all of which will change the T8 ratio. This consultant's methodology was just junk science.

Another commonly misrepresented age-dating method is the Christensen and Larsen Age-Dating Model for diesel fuels.² The Christensen and Larsen model is based on the assumption that n-heptadecane (n-C17) aerobically biodegrades in the environment at a constant and uniform rate while pristane (2,6,10,14-tetramethylpentadecane or Pr) is resistant to biodegradation. Christensen and Larsen reported a linear relationship when the n-C17/Pr ratio is plotted against the known age of diesel spills from 12 sites in Holland and Denmark over a 20-year period. In order for this model to work, the biodegradation of n-C17 must be aerobic, uniform, and consistent over time. Christensen and Larsen placed a number of caveats on the use of the model and many aspects of the method are still raising a large caution flag over its use; however, many "experts" ignore the caution flag and just plug numbers into equations based on the Christensen and Larsen Model to age-date petroleum releases.³ This happened in a recent case where a consultant tried to age-date a release of No. 6 fuel oil. The consultant ignored the fact that the physical properties of No. 6 fuel oil are different from diesel fuel and what effect these differences have on aerobic biodegradation. Christensen's and Larsen's caveats were ignored. The consultant also used a sample containing more than 30% No. 6 fuel oil for the age-dating. At this concentration, there is free-phase oil present, which inhibits microbial action. With free-phase product present, there is less aerobic biodegradation on the interior of the product than on the surface. Thus, the biodegradation of the No. 6 fuel oil was not constant and uniform as required by the model. The age-date calculated by the consultant was nothing more than junk science.

Environmental Chemistry, Age Dating, Junk Science

Engineering Sciences Section - 2015

D35 Using SESOIL to Evaluate Contaminant-Release Time Frames in an Environmental Litigation Context

Mark A. Kauffman, Jr., BS*, McLane Environmental, LLC, 707 Alexander Road, Ste 206, Princeton, NJ 08540; and Charles F. McLane, PhD, McLane Environmental, LLC, 707 Alexander Road, Ste 206, Princeton, NJ 08540

The goal of this presentation is to demonstrate the application of the United States Environmental Protection Agency (USEPA)-developed Seasonal Soil (SESOIL) model to analyze contaminant transport through the unsaturated zone to estimate, in conjunction with other environmental data and forensic techniques, contaminant-release timeframes.

This presentation will impact the forensic science community by providing pertinent information to illustrate how a tool developed primarily for evaluation of environmental data in a regulatory context can be used to develop scientifically defensible arguments in environmental litigation matters.

SESOIL (SEasonal SOIL compartment model) is a 1D vertical fate-and-transport model for the unsaturated zone, which is designed to simultaneously simulate soil water movement and contaminant transport. The model is based on mass balance and partitioning of the contaminant between dissolved, sorbed, vapor, and pure phases. SESOIL simulates long-term pollutant fate and migration in the unsaturated soil zone, considering: hydrologic cycle of the unsaturated soil zone; pollutant concentrations and masses in water, soil, and air phases; pollutant migration to the groundwater; and, pollutant volatilization at the ground surface.¹

The SESOIL model was developed by the USEPA, and has been adopted by a number of federal entities (e.g., the United States Department of Energy) and state regulatory bodies (e.g., the New Jersey Department of Environmental Protection) for use in evaluating future impacts to groundwater from soil source zones. Based on this widespread regulatory acceptance, the SESOIL model provides a valuable, scientifically defensible tool that can be used in conjunction with other site-specific data to evaluate fate and transport of contaminant travel times in the unsaturated zone in the context of environmental litigation. Specifically, assuming that the approximate date in which groundwater beneath an overlying column of soil was first impacted can be reliably estimated, SESOIL modeling analyses can be performed to provide estimated timeframes of contaminant release at or near the land surface, which is often an important aspect in environmental litigation matters.

A case study will be presented in which the SESOIL model was used in an insurance litigation case to estimate the approximate start date of a leak from an underground petroleum pipeline. Site-specific data, including soil texture information provided by lithologic logs, soil concentration data from samples collected from vadose soils, and information obtained from other site investigation documents were used to define model inputs. The results of the SESOIL analyses were then compared with site groundwater quality data, including sample results for benzene and the gasoline additive Methyl-tertiary Butyl Ether (MtBE), to estimate the approximate date of commencement of the pipeline release. Corroboration of the SESOIL model results by other lines of evidence from the site historical record, as well as other considerations that should be taken into account when utilizing SESOIL modeling methods for forensic purposes, will also be discussed.

Engineering Sciences Section - 2015

D36 Where Is New Jersey Going?

*James S. Smith, PhD**, Trillium, Inc, 28 Graces Drive, Coatesville, PA 19320-1206; and *Carol A. Erikson, MS*, 1433 Yarnell Station Boulevard, Knoxville, TN 37932

After attending this presentation, attendees will be aware of an important recent ruling in New Jersey that affects the practice of environmental forensics.

This presentation will impact the forensic science community by providing attendees with the background needed to determine how a 2013 court ruling will affect their practice of environmental forensics.

A dry cleaning site in New Jersey was found to be contaminated with the dry cleaning solvent Perchloroethylene (PCE); another name for this chemical is tetrachloroethene. Historically, this facility was used by two parties, the first of which ran the dry cleaning operation from 1957 to 1982. The second party took over in 1982 and continued the cleaning operation through 2011. The property was owned by a third party, having acquired it by deed in 1971. After soil and ground water contamination was found on the site in 2009, the court determined that the second party to operate the dry cleaning business was solely responsible for all of the PCE contamination. Although the second party alleged that the first party was also liable, the court disagreed because there was no proof (i.e., documentary evidence or eyewitness testimony) of actual discharges or releases at the dry cleaners prior to 1982. Simply stated, if it wasn't observed happening, and/or documented, then it did not (legally) occur.

This opinion renders reasonable environmental forensics a waste of time, effort, and money.

Forensic analysis is the recreation of an incident or many incidents that, most often, were not observed by anyone at the time they happened. The precedent set by this New Jersey ruling means that, from this point forward, there must be direct evidence of actual discharges — an often impossible standard.

Equally disturbing is that the court allowed an expert witness to offer testimony regarding his “age-dating” of the PCE release. This expert testified that the high ratio of PCE to its anaerobic biodegradation breakdown products (Trichloroethylene (TCE), cis-1,2-Dichloroethylene (cis-1,2-DCE), and vinyl chloride) was the result of “relatively recent” releases because the PCE had not had time to degrade in substantial amounts. This is pure junk science and totally false: it is not possible to age-date PCE in the environment based on parent-to-degradation product ratios or by any other chemical means. But, it sounds good, and it advanced their case.

The 2013 ruling that a party must be shown, by a preponderance of direct evidence, to have committed a discharge that was connected to the environmental damage will do nothing to ensure that all polluters are held accountable for their actions. It will instead promote science-based advocacy.

Dry Cleaner, Age-Dating, Junk Science

Engineering Sciences Section - 2015

D37 Federal Court Testimony — Tennessee Valley Authority (TVA) Kingston Slurry Ash Spill

Gary R. Brown, BS, 215 W Church Road, King of Prussia, PA 19406*

The goal of this presentation is to help attendees learn how to evaluate large volumes of information in preparation for federal court testimony on a large-scale environmental case.

This presentation will impact the forensic science community by describing how potential expert witnesses are often retained to play a key role on projects, even though the whole case involves many disciplines. There may be a large volume of historical data and many moving parts during legal discovery. The performance of an expert witness in federal court depends on the expert's ability to stay abreast of findings, and new facts, during the discovery process. This presentation will describe how the evaluation steps during this case were undertaken, as a review of data, reports and correspondence revealed that promises to monitor the water levels in a coal ash pile were made then found not to be done. This presentation will focus on the nature of specific testimony and questioning and how the court's decision(s) relied in part on this testimony.

A coal fly ash slurry spill occurred just before 1:00 a.m. on Monday, December 22, 2008, at the TVA Kingston Fossil Fuel Power Plant, in Roane County, TN. A reported 1.1 billion gallons of coal fly ash slurry was released from a large vertical wet pile which has been variously described as a solid waste containment area or a diked area with ponds, much of which was found to be saturated. "Dredge cells" were not constructed as described in a number of documents and drawings and the slurry traveled across the Emory River and the Swan Pond embayment, covering up to 300 acres of land, damaging homes, and flowing into waterways, including the Emory River and the Clinch River, which are tributaries of the Tennessee River. The coal ash release has been called one of the world's worst environmental disasters and was the largest coal ash release in United States history.

Questions arose regarding why the environmental release happened and who had responsibility, from an environmental standpoint, for the release. A professional engineer in 18 states, including Tennessee, provided expert witness testimony in federal court. A team of experts were retained by the parties whose homes and/or property were damaged by the coal ash release, a large number of documents from TVA and the Tennessee Department of Environmental Conservation were reviewed, and a large volume of documents continued to be produced during the discovery process.

Certain items presented in the engineer's federal court testimony were not answered by TVA and aspects of Subtitle D Resource Conservation and Recovery Act provisions were an issue. Ultimately, the court decided that there was liability on the part of TVA, based on a number of key technical facts and permitting items. Key to the court's decisions were responsibilities for properly monitoring and operating the disposal facility.

This presentation will describe the process of reviewing documents, coordinating with legal counsel on the key issues, and the approach for presenting testimony in an appropriate and organized manner. There was testimony focus on environmental management issues that did not receive attention but had been promised to regulatory agencies in the time frame leading up to the major coal ash release. When the release from the 84-acre unlined aboveground ash fill area occurred, which was 60 feet high, a mud flow wave reached out over more than 300 acres and contamination was experienced for many areas down the Emory and Clinch Rivers.

Potential expert witnesses can learn how to evaluate and focus on key issues related to large-scale environmental problems when faced with very large volumes of data, historical information, and reports to provide testimony in federal court, which focuses on the causes of, and the liability associated with, major environmental problems.

Federal Court, Testimony, TVA Kingston

Engineering Sciences Section - 2015

D38 Environmental Forensics Vanity Journals

James S. Smith, PhD*, Trillium, Inc, 28 Graces Drive, Coatesville, PA 19320-1206; and Carol A. Erikson, MS, 1433 Yarnell Station Boulevard, Knoxville, TN 37932

After attending this presentation, attendees will better understand the peer-review process for scientific literature.

This presentation will impact the forensic science community by providing attendees with insight into how improperly peer-reviewed publications will affect their practice of environmental forensics.

In court, the judge is the gatekeeper for the expert opinions rendered in litigation, and the United States Supreme Court has suggested certain criteria the judge can use to allow or ban an expert's testimony. One of these criteria is whether the scientific methodology used to develop the testimony and opinions is published in a peer-reviewed journal. This becomes an extremely important criterion because the peer-review process is the place where scientists have the opportunity to remove "junk science" (i.e., data produced using improper or non-scientific methodology) from their own scientific literature. It is the scientist's way of self-policing their discipline.

The expectation for scientific peer review is that it will be done with extreme rigor. No rubber stamps here. The sampling protocols, chemical analytical methods, quality control, data interpretation, and conclusions are all under the microscope. The publication must have merit for advancing the known realm of information of the paper's subject matter.

One expects the article to be critically challenged by each reviewer. Corrections, changes, and additions are normally necessary prior to approval for publication. More importantly, papers submitted to a peer-reviewed scientific journal that are below par should not appear in the publication. If the submitted paper was sent to a reviewer who does not have the required training, education, or experience to critically analyze the subject matter, then the reviewer will send it back to the editor so it can be re-assigned to another reviewer with the proper credentials.

Unfortunately, many published papers in the field of environmental forensics are not critically peer reviewed, despite being published in a self-proclaimed peer-review journal. This failing fosters the expert's sense of safety in opinions that speculate scenarios without a scientific basis and encourages opinions based on what might be possible, rather than what is more probable. The topic of age-dating a release is the elephant sitting on the head of this pin.

The following publications are the focus of this presentation: (1) Oudijk, Gil, "Age Dating Heating-Oil Releases, Part 1, Heating-Oil Composition and Subsurface Weathering," *Environmental Forensics*, Vol. 10, pp. 107-119, 2009; and, (2) Oudijk, Gil, "Age Dating Heating-Oil Releases, Part 2, Assessing Weathering and Release Time Frames Through Chemistry, Geology and Site History," *Environmental Forensics*, Vol. 10, pp. 120-131, 2009.

This presentation will point out some of the most egregious problems with this "peer-reviewed" reference. The concern is real because the information presented in these papers, which should never have been published in a peer-reviewed journal, is presently being used in litigation. The lack of rigorous scientific peer review prior to publication shows a lack of respect for the justice system and forensic science.

Peer Review, Scientific Literature, Publication

Engineering Sciences Section - 2015

D39 Sometimes Electrical Work Results in Damage, Fire, Injury, or Electrocution

Thomas P. Shefchick, BSEE, 853 Enisgrove Way, The Villages, FL 32163-2447*

The goal of this presentation is to illustrate how to use burn patterns to determine the origin and cause of an electrical problem.

This presentation will impact the forensic science community by discussing methods to determine the cause of an electrical occurrence.

The first case concerns an 8,000 horsepower synchronous motor that broke down and subsequently was repaired by an electrical mechanical apparatus repair company. Three months after the motor was repaired and reinstalled, problems were encountered. The motor's rotor had been rewound after the initial breakdown. Rewinding a rotor involves taking it completely apart and replacing the electrical components that produce its magnetic fields. Inspection of the motor installation found no evidence of damage. Therefore, the motor was removed and disassembled. The motor's stator showed no visible damage but the rotor's components had sustained heat damage. The rotor had cooling fins to ventilate its heat during operation; however, the motor repair company had installed the fins in a manner that would entrap the heat which caused damage to the rotor windings. This problem could have been prevented by marking the proper cooling fin orientation before the rotor was disassembled.

The second case discusses mufflers which had been installed on generators that supplied electrical power to a luxury residential establishment. The mufflers were installed to reduce the noise produced by the generators. Three generators were installed in a stand-alone building and controlled by a computer system which rotated operation of the generators. One evening the computer system failed to transfer from generator number 1 to generator number 2 and subsequently the roof of the generator building caught fire. Examination of the burn patterns indicated that heat leaking from a muffler connection ignited the combustible roof. The mufflers were removed from the generators and their internal metal components were found severely heat damaged which indicated that the problem originated within the mufflers. Analysis of the materials in the mufflers revealed that the wrong type of metal was used to manufacture them.

The third case involves a severe electrical injury at a luxury hotel. The hotel had an electrical contractor install equipment to improve their electrical power factor. The purpose of improving the power factor was to reduce their electrical utility bill; however, the contractor was not able to complete the installation because a door covering the control components did not fit properly. When the correct door was obtained, the contractor suggested that a hotel employee could install it. Subsequently, a maintenance man of the hotel was severely electrically burned when he attempted to install the door. The burn patterns on the door and motor control center indicated that his screwdriver slipped while attempting to attach the door. This problem would not have occurred if the motor control center was completely de-energized as required by warning labels on the motor control center.

The last case relates to electrocution at a school. The school had been experiencing a problem with a steamer oven in the kitchen of their cafeteria. A repair company was contacted and sent an electrical repairman to fix the steamer oven. The repairman removed covers from the steamer oven to examine the operation of its internal components. While examining the components, the man was electrocuted. Components on the interior of the steamer oven had burnt hair on them which indicated that the man's head had made contact with the electrically energized components. In addition, the workman was surrounded by grounded metal equipment. This problem could have been avoided by mounting a disconnect switch at the steamer oven and providing sufficient workspace around equipment as required by the national electrical codes.

Burn Patterns, Electrical, Electrocution

D40 Hot Air Balloon Fires, Power Lines, Product Liability

Helmut G. Brosz, PEng, BASc, Brosz Forensic Services, 64 Bullock Drive, Markham, ON L3P 3P2, CANADA; and S.B. Addison Larson, Sherman, CT, 06784*

After attending this presentation, attendees will understand the mechanism of failure, accident prevention, and outcomes of hot air balloon power line strikes. Product liability issues relating to an actual case and potential design changes to prevent short circuits will assist the legal and forensic engineering community.

This presentation will impact the forensic science community by providing attendees with an understanding of the mechanisms, causes, and product liability issues of hot air balloon power line strikes.

Hot-air ballooning can be an enjoyable recreation. Pilots fall under Federal Aviation Administration (FAA) jurisdiction with a “lighter-than-free-air balloon” rating. Per Federal Regulation Sec 61.68, commercial balloon operators are required to maintain an FAA mandated pilot’s license, type-specified for the apparatus. Pilots are trained in collision avoidance under 14 CFR and a ground crew is required to assist with takeoff, flying, and landing. What is not often mentioned, or mediated upon, is that 34 hot air balloon accidents occur per 10,000 flight hours in the United States. Of these, 12% are due to balloon convergence with power lines/utility poles and 80% of all combined fatalities are the result of an accidental power line strike.

One of the most recent accidents occurred on May 9, 2014, in Ruther Glen, VA, with an event originating outside of Doswell, VA. There were three fatalities and a debris path 1.75 miles long. The National Transportation Safety Board (NTSB) reports that between 1983 and 2007 there were nine power line contacts involving balloons resulting in 17 fatalities.

Most power line strikes occur at takeoff and landing sites, close to populated areas with distribution power lines ranging in voltage from 4,160 to 13,200 to as high as 34,500 volts phase-to-phase. The distance between phases ranges from about two to six feet depending on the type of construction. Sub-transmission lines ranging from 44,000 to 69,000 volts, or transmission lines ranging from 115,000 to 735,000 volts with 10- to 30-foot spacing between phases, may be nearby. The National Electrical Safety Code (NEC) sets out phase-to-phase spacing and phase-to-ground spacing for power lines.

Power lines are rarely insulated but are bare copper or aluminum conductors. While contact with one phase may occur without incident to a balloon, contact between phases is much more dangerous. Incidents where a bird’s wingspan shorted two phases, electrocuting the bird, igniting its feathers, and starting a fire have been investigated. Balloons, given their much greater size and potential conductivity of metallic components, can likewise make phase-to-phase contact or get tangled up and cause a short circuit.

Given the foreseeable dangerous risk of contact, product liability can become a major issue, especially regarding the construction and design of the balloon basket. Those who design, manufacture, sell, or furnish products that are unsafely defective may be liable — even strictly liable for defects that make a product unreasonably dangerous. Yet despite the foreseeability of such accidents, basket design has not changed significantly.

The construction of a balloon assembly falls under the jurisdiction of the NTSB. The balloon envelope is made of nylon, which is an insulating material and would not short circuit a power line. The problem is the metallic parts of the balloon, which are not insulated. The wicker basket usually contains an aluminum frame and four propane fuel tanks which are either stainless steel or aluminum. Thus, when a basket with its frame and tanks comes in contact with a power line a phase-to-phase short circuit may occur. The KWh quantity of energy in the ensuing arcing is usually sufficient to melt and vaporize the aluminum or stainless steel and perforate the propane tank wall, releasing and igniting the propane and the wicker basket before any power line fuse or relay operates to clear the fault. The hot gas also rises, enters, and heats up the balloon causing an uncontrolled rate of climb. The occupants and pilot have only one choice...jump!

Similar accidents have been investigated and an insulation system has developed and tested in the laboratory to prevent the short circuits occurring in most instances. This insulation concept has been presented in successful product liability litigation involving balloons. This presentation includes the details of one such hot air balloon fire/power line strike, fatality, injury, and associated litigation outcome.

Hot Air Balloon Fires, Power Lines, Product Liability

Engineering Sciences Section - 2015

D41 Forensic Engineering Investigation of Burn Injuries in a Defective Spa Pool Light Installation

A.K. Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will understand the need for a complete forensic engineering investigation and evaluation.

This presentation will impact the forensic science community by explaining the need for a thorough forensic engineering investigation, which systematically evaluates the injury evidence, the mechanism of injury, the type and properties of the light, the methods of installation, the electrical codes that are applicable, and the methodology of verifying laboratory tests in the field.

A middle-aged woman who was paralyzed below the waist enjoyed the benefits of a spa pool at a major national chain hotel. As a disabled person, she was particularly grateful that she had full access to the hotel hot tub and spa pool facility. She was assisted by her caretaker who helped her wheelchair to the pool and helped her into the water, using the handrail and steps provided.

After she left the pool, it became apparent that she had suffered third-degree burns along her back, which required hospitalization and significant treatment. She had been burned by a light that was installed in a defective manner and in fact that same light had the further potential to cause serious harm to others.

This presentation reconstructs the events and factors leading up to the injury event and concludes in the final and site inspection which corroborated the initial testing, along with some unexpected surprises. Attendees will benefit from this presentation by gaining an understanding of the need for a thorough forensic engineering investigation, which systematically evaluates the injury evidence, the mechanism of injury, the type and properties of the light, the methods of installation, the electrical codes that are applicable, and the methodology of verifying laboratory tests in the field.

The light at issue was a halogen bulb mounted in a watertight enclosure, manufactured for use in a pool; however, in this case, the light was mounted in the second step of a stair section that allowed persons to enter the spa pool. By mounting this light in the stair “kicker,” the vertical wall between adjacent stairs, this light was not submerged as would be the case in the manufacturer’s intended installation, but rather was adjacent to users as they entered the pool or sat on the steps. In this case, as the plaintiff sat on the step she was unaware that her body was in contact with an exceedingly hot surface.

A halogen light exemplar was examined in the laboratory and fitted in an underwater test fixture. A test device, an instrumented sponge, was developed to measure the temperature-over-time relationship, resulting in surface contact temperatures of 195°F in a matter of just a few minutes. Photos and graphs of this measurement process will be presented. Furthermore, a pork surrogate was developed to corroborate the burn patterns and depth of thermal penetration observed in the medical reports of the injuries to the plaintiff.

These findings were then taken to the site investigation. Actual tests in the hotel spa pool confirmed the lab results. This site testing was performed in the presence of 16 attorneys, experts, and unidentified participants in the case. Some of these individuals actually placed their hands against the hot light and subjectively confirmed the nearly instantaneous pain. This was a somewhat unusual event that seldom occurs in site inspections and will be further discussed.

As a follow-on to the inspection, the electrical circuit was inspected, which required the partial dismantling of the spa wooden deck covering. Several more surprises were discovered as it turned out that the installation was defective, the Ground Fault Interrupter (GFI) circuit was deficient, and the entire installation posed a real electrocution risk to anyone using the facility.

The case was settled, but a letter was sent to the city and the hotel chain advising them of the critical safety issues discovered during the site inspection. This was done as part of the code of responsibility of the Professional Engineering License in that state.

Spa Pool, Thermal Burn, Halogen Light

Engineering Sciences Section - 2015

D42 Sometimes Deficient Electrical Installations Result in a Fire

Thomas P. Shefchick, BSEE, 853 Enisgrove Way, The Villages, FL 32163-2447*

After attending this presentation, attendees will understand that electrical deficiencies are frequently missed by inspectors and that it sometimes takes several years for these deficiencies to cause a fire. Three fire cases will be utilized to show what basic visual inspection would have revealed. In addition, the use of burn patterns (damage caused by heat) to determine the point of fire origin and cause of the fire will be demonstrated.

This presentation will impact the forensic science community by illustrating that many electrical installations are not sufficiently inspected.

A fire occurred in a fast-food restaurant located on the 1st floor of a large building in the downtown area of a resort community. The burn patterns on the building and in the restaurant indicated that the fire originated in the basement. Minimal fire damage was found on the 1st floor of the building but the 2nd floor of the building was completely destroyed. The entire building was condemned and had to be demolished. Examination of the burn patterns in the basement indicated that the fire originated at a ceiling joist where an electrical cable was located. The cable supplied power to a toasting oven located in the fast-food restaurant. It had been installed three years prior to the fire by a contractor renovating the facility from an ice cream parlor to a fast-food restaurant. An architect had been retained for the renovation; however, the contractor had used an undersized electrical cable and did not install it in an electrical conduit (metal pipe) as specified by the architect. In addition, the local electrical code required the cable to be installed within a thermally protected wall. A visual inspection of the basement ceiling would have revealed the electrical deficiency.

Another fire occurred in a retirement condominium community. The burn patterns in the fire building indicated that the fire originated in a common wall between the kitchen of an apartment and a shower stall of another unit. The point of fire origin was an electrical junction box in the wall for the oven located in the kitchen unit which sustained minimal fire damage. Aluminum wiring from the apartment's electrical panelboard was spliced to stranded copper wiring from the oven in the electrical junction box. This is a violation of the National Electrical Code which requires that conductors of dissimilar metals shall not be intermixed in a terminal or splicing connector where physical contact occurs between the dissimilar conductors such as copper and aluminum. This condominium complex had a reputation for having problems with aluminum/copper wiring and over the years several electrical renovations had been conducted without resolving all of the problems.

The third case study is a wildfire which is a large destructive fire that spreads quickly over woodland or brush. Inspection of the burn patterns on the terrain and vegetation indicated that the fire originated near a highway advertising billboard. The billboard had been damaged by high-velocity winds in the area. The electrical conduit (metal pipe) supplying power to the billboard's lighting system was damaged and broken apart. A metal detector revealed the presence of metal on the ground beneath the billboard. The high-velocity winds had caused the electrical wiring in the conduit to short-circuit and drop molten metal onto dry brush on the ground thus initiating this fire. The billboard's conduit was Electrical Metallic Tubing (EMT) which is thinner than rigid electrical conduit. In addition, EMT is simply pushed together whereas rigid electrical conduit is threaded together and sturdily mounted. The local electrical utility requires rigid electrical conduit to be used and the billboard has been inspected on a yearly basis for more than 20 years.

Burn Patterns, Conduit, Copper/Aluminum

D43 Did Radiant Heat From Electric Coils Cause a House Fire?

Darren Franck, MSME, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304; and Harold Franck, MSEE, PE, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304*

After attending this presentation, attendees will better understand safety features in modern heating and cooling equipment and their applicability to a residential fire. Attendees will also gain an understanding of the importance of testing in forensic investigations.

This presentation will impact the forensic science community by highlighting the pitfalls of untested hypotheses in origin-and-cause investigations.

This case study involves a residential fire in southern West Virginia. A two-year-old heat pump serviced a double-wide manufactured home. The ducts and plenum boxes were replaced at that time in order to provide heated and cooled air to the home and one-story addition. On the date of the fire, the heat pump had stopped operating and the installer visited the home to return the unit to working order. Roughly 20 minutes after fixing the unit, a fire originated under the home, which eventually destroyed the structure.

An investigation was commenced by the homeowner's insurance company. The experts hired to perform the origin-and-cause investigation quickly determined that the fire started within the supply ducts near the heat pump. Particular attention was paid to the electric heating coils and control panel. The experts claimed that the unit was installed without thermal fuses, which are intended to shut off the second stage of heat when certain temperatures are reached. Additional installation deficiencies were identified, including insufficient duct diameter, improper filter, and inadequate fan setting. The homeowner had been notified of the fire by black smoke emanating from the floor registers. The experts demonstrated similar smoke by applying flames to the inner plastic jacket of the flexible ducts. The experts determined that the fire was caused by radiant heat from the electric heating coils. The experts hypothesized that the installation deficiencies allowed temperatures to rise to the point that the inner jacket of the duct ignited.

A separate origin-and-cause investigation was performed, which confirmed the area of origin. Initially, the experts' hypothesis seemed plausible, especially given the apparent lack of incendiary causes or other ignition sources near the area of origin; however, in order to adhere to the scientific method, all hypotheses must be tested in order to be confirmed as a theory. An equivalent heat pump was purchased and installed at this study's facilities. Additionally, the ducts and plenum boxes were reconstructed to depict airflow conditions at the subject home.

Several thermocouples were placed in critical areas in order to document the testing. Temperature readings were gathered near the electric heating coils, within the heating duct a few feet downstream of the discharge point, within the plenum box, and outside the unit to record ambient temperatures. In total, nine tests of the exemplar heat pump were performed. Normal operation of the unit resulted in peak temperatures of 220°F near the coils and 120°F in the supply duct. Subsequent tests involved progressive removal of safety components and increasingly obstructing airflow. Initial restrictions in the airflow caused temperatures to increase modestly; however, the electric heat sections cycled off, indicating proper function of the thermal switches.

As alleged by the other experts, the safety components were removed. Specifically, the high- and low-temperature switches were wired over, which caused continual operation of the electric heat section. Airflow restrictions were maintained to represent a worst-case scenario. Despite these efforts, temperatures stayed well below the ignition point for common plastics. Moreover, bypassing of the limit switches resulted in component failures on the control panel of the exemplar heat pump. Such component failures were not present during the origin-and-cause investigation of the subject heat pump. Air temperatures near the coils could have resulted in ignition of highly combustible materials, such as paper and dust. Such materials were introduced to the electric heat section. Although ignition occurred, the operation of the blower effectively snuffed out these small fires. None of the testing resulted in ignition of the duct liner.

The testing highlights the need for forensic engineers to fully test their hypotheses. While the opposing experts presented a compelling case, the application of the scientific method disproved their conclusions. Despite the fire occurring less than an hour after the heat pump was serviced, the installer was able to successfully defend his company against litigation. Although there are still uncertainties as to the exact cause of the fire, the allegations of installation and repair defects were disproved.

Radiant Heat, Electric Heating Coils, Ignition Temperature

D44 Forensic Engineering Evaluations of Underground Gas Line Leaks: Residential Explosions Involving Marijuana-Growing Operations in Colorado

Michael D. McDowell, MS, 24665 E Ontario Place, Aurora, CO 80016*

The goal of this presentation is to educate attendees on the cause and origin of gas line leaks and the potential consequences of altering buried gas lines. Attendees will learn several important principles of gas migration in soil, underground utility placement, trench construction, yield stresses in pipe, and the importance of performing utility clearance prior to excavating soil.

This presentation will impact the forensic science community by serving as an example of potential consequences associated with impacting buried utilities. It will also increase an investigator's awareness of various conditions that should be assessed at the time of investigation. This presentation will present photographic documentation for two case studies and discuss the relevant findings and conclusions of each matter.

Case Study 1: A single-family residence, located a few miles from Vail, CO, was heavily damaged during a June 2010 fire that occurred as the result of a propane gas leak/explosion. The source of the propane was a 1,000-gallon tank that was buried approximately 75 feet north of the northeast corner of the residence. The source of the propane leak reportedly occurred at the connection between a buried polyethylene tube (i.e., supply line) and the gas line connection/penetration into the residence.

Some parties alleged that the connection between the underground polyethylene tubing and the adapter at the residence was problematic and/or inappropriately fastened. Because of these alleged issues, the polyethylene tubing became disconnected under loads that it was reportedly designed to withstand (assuming it was connected appropriately). Others alleged that inadequate soil compaction led to soil settlement which caused the gas line separation at the residence. Based on the available data, it is likely that a combination of issues contributed to the gas line separation. The potential issues evaluated as parts of this case study included: (1) soil settlement caused by inadequate compaction; (2) the inherent characteristics of onsite soils; (3) the introduction of water from a marijuana grow operation in the residence's basement; (4) the introduction of water from other sources; and, (5) the material properties of the polyethylene tubing.

Case Study 2: A natural gas explosion occurred in April 2011 at a single-family residence in Denver, CO. This explosion caused serious damage to the structure and bodily injury to the homeowner. According to the Denver Police Department report, the cause of this explosion was linked to a natural gas leak on the adjoining property to the west (a marijuana grow operation). The natural gas leak reportedly occurred due to a separation in a one-half-inch diameter steel gas line (near the gas meter at the adjoining property) and was ignited when the homeowner lit a cigarette.

The litigation and engineering evaluations in this matter primarily focused on two potentially responsible parties who likely impacted the gas line while performing excavation activities on the adjoining property. One party performed excavation activities approximately 14 hours before the explosion and the other party excavated approximately 36 hours before the explosion. Neither party admitted to impacting the gas line; therefore, an engineering evaluation was performed to assess whether gas was more likely to migrate from an underground leak within the shorter time frame. The potential issues evaluated as parts of this case study included: (1) the porosity of soil; (2) gas flow rates; and, (3) engineering calculations regarding migration of gas under various scenarios and assumptions.

Engineering Evaluation, Utility Lines, Fire/Explosion

Engineering Sciences Section - 2015

D45 Electrical Safety Components Sometimes Cause Damage

Thomas P. Shefchick, BSEE, 853 Enisgrove Way, The Villages, FL 32163-2447*

After attending this presentation, attendees will understand that electrical safety devices must be correctly designed and maintained to prevent damage or injury.

This presentation will impact the forensic science community by imparting the value of proper electrical design and maintenance of safety components.

A homeowner had developed the habit of soaking his children's clothes in the washing machine of a stacked washer/dryer overnight and letting the water run into the washer with its top open until the water was stopped by an overflow protective device. His intention was to let the children's clothes soak overnight in the washer before closing the lid and washing them in the morning; however, one evening the water overflow device failed to stop the water flow and his house was flooded with water. The washer/dryer was disassembled to inspect its control components. Lint from the dryer was found blocking the mechanism of the water overflow device and preventing it from stopping the water flow.

The water overflow device's mechanical components should have been enclosed to prevent lint from jamming their mechanical motion, since lint should be expected from the dryer on top of the washer.

Another case involved a computer surge arrestor. The surge arrestor had caused serious smoke damage in a residence. The surge arrestor was rated at 15 amperes and its overload device did not activate. A hole was found burned through its plastic enclosure. Inspection of its interior components found that the overload device was improperly wired to the incoming power line. An electrical power supply wire went to a printed circuit board ahead of a 25-ampere fuse which had not blown. Evidence of electrical short-circuiting was found between the power supply conductor and ground conductor on the printed circuit board. This device was rated at 15 amperes and its printed circuit board should not have been protected by a 25-ampere fuse.

The third case involved a man that was injured and died while operating a motorized scissors-lift vehicle. The gentleman had rented the vehicle to construct a storage structure on his property. While driving it down a hill away from the building, he hit a bump, was knocked off the front of the vehicle with its control box in his hands and dragged down the road underneath the vehicle. He sustained serious injuries and died. The control box was mounted on a removable gate on one end of the unit's platform. The gate had bounced off because it was not secured by a cotter pin beneath the platform that would secure the gate to the platform. The control box had an emergency stop button but no wires or components to activate an emergency stop. Furthermore, wiring diagrams of the control box indicated that it should contain a Mercury reed switch that would stop the vehicle if the control box moved out of position.

The rental company did not provide an operating manual with the unit or maintain it as required by law.

Water Damage, Smoke Damage, Emergency Stop

Engineering Sciences Section - 2015

D46 A Multidisciplinary Analysis of a Complex Motorcycle Fatality

Matthew A. Ivory, BS, 3720 E LaSalle Street, Phoenix, AZ 85040; Parris Ward, JD, Biodynamics Engineering, Inc, 17383 W Sunset Boulevard, Ste 290, Pacific Palisades, CA 90272; Michelle R. Hoffman, MS, 3720 E La Salle Street, Phoenix, AZ 85040; and Carley C. Ward, PhD, Biodynamics Engineering, Inc, 3720 E La Salle Street, Phoenix, AZ 85040*

The goal of this presentation is to demonstrate the value of a multidisciplinary approach to the reconstruction of a fatal motorcycle crash.

This presentation will impact the forensic science community by presenting a case study where accident reconstruction, vehicle inspection, biomechanics of injury, structural and helmet testing, scene investigation, and innovative detailed analysis of the surveillance video all played an important role in resolving the cause of the crash and the timing available to the motorcycle rider.

A motorcycle rider sustained a fatal head injury when he attempted to avoid striking a semi-truck and trailer that made a U-turn in front of him. He was pronounced dead at the scene after landing in a grassy area behind a 66-inch wrought iron fence. He was wearing a non-DOT-approved novelty helmet and sustained a massive and unusual skull fracture. The accident occurred in the dark, early morning hours. There was little traffic and there were no witnesses to the event. The following questions had to be answered: Could the motorcycle rider have avoided the collision? How fast was he going? Did he or his motorcycle actually strike the semi-truck? What did his head strike and at what speed? Could his brain injury have been prevented or lessened had he been wearing a DOT-certified helmet? How did he end up on the other side of the fence? This presentation describes how these questions were addressed scientifically.

Although no one saw the accident, surveillance video was obtained from the security system at a nearby business. Because the video taken from a distance was of low resolution and at night, it was difficult to extract meaningful data from the video. A high-resolution camera was mounted in the same location and at the same angle. The images from both cameras were correlated in a photogrammetric study to identify distant landmarks and lights which were not easily discernable in the original footage. Speeds of vehicles on the adjacent roadway were also calculated. Using this data, it was possible to better approximate the speed of the motorcycle seen in the surveillance video. An accident reconstruction was developed using marks in photographs and at the scene that had not been considered in an earlier analysis. Subtle damage to the motorcycle and markings on the rider and his clothing were identified and correlated with contact to the rear of the trailer.

The motorcycle rider's novelty helmet showed that it was split in half. It was originally hypothesized that the damage was caused by striking a wrought iron fence post or the edge of the curb; however, closer examination showed contact marks from a distributed contact with dull irregular scratches, not the sharp or deep scratches one would expect in such an impact scenario. Instrumented helmet drop tests using a Hybrid III dummy head were performed using helmets similar to the subject helmet and a DOT-certified helmet of the same overall style. Helmeted heads were dropped onto curb sections, asphalt, and fence pieces from varying heights at speeds up to 21.5mph. Head accelerations and speeds were recorded. Through testing, the subject contact marks were shown to be inconsistent with a curb, roadway surface, or a fence impact.

Since the extensive fracturing on the subject helmet could not be reproduced in the testing, the actual impact was at speeds greater than the tested 21.5mph and the helmet impacted an object other than those tested. Using the information from the surveillance video, injuries to his body, the marks identified in the photographs, and damage to the motorcycle's handlebars, a final crash reconstruction was performed. Finally, a kinematic analysis revealed how, after making contact with the trailer and his motorcycle striking the curb, he was launched headfirst and face up over the fence into the trunk of a palm tree.

In conclusion, this complex analysis was effective in answering the questions posed, by considering and analyzing all the evidence available in a cooperative manner. Confluence of results from these various studies reveal what actually occurred in this massive head injury event.

Motorcycle Reconstruction, Novelty Helmets, Surveillance Video Analysis

Engineering Sciences Section - 2015

D47 Forensic Engineering Critical Site Photogrammetry and the Use of GPS in a Ski Collision Case

A.K. Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will understand some of the complexities of the reconstruction of ski terrain collisions, photographic techniques, expert errors, and the use of novel technologies.

This presentation will impact the forensic science community by presenting a collision between two skiers at a western ski area which resulted in severe head and bilateral wrist injuries to the smaller, female skier.

A collision between two skiers at a western ski area resulted in severe head and bilateral wrist injuries to the smaller of the two, a female. Ensuing litigation excluded the ski area, but nonetheless, ski patrol reports on the incident proved to be critical to the accurate identification of the collision site and the trajectories and speeds of the two skiers.

This presentation outlines the need for systematic orthographic photos to locate otherwise unremarkable features in the ski terrain environment. Furthermore, it is imperative that opposing experts be sufficiently skilled in interpreting this information to reach reasoned conclusions, especially on terrain with which they have minimal familiarity.

Both of these factors will be developed in detail with site photos and case evidence.

In general, placing a known object in the scene allows a series of photos to be taken that will locate the spot at a future date. By judiciously selecting trees, poles, towers, buildings, landscape features, and features on ridgelines, a person can take a set of photos that will preserve the alignment of the known object and background features along three or more intersecting lines of sight.

As it happened, this litigation was initiated several years after the event. The collision reconstruction relied on the accurate positioning of the collision scene, which was made possible by the site documentation at the time of the collision.

These reports included witness statements, first responder ski patrol documents, and follow-on investigative interviews. The basic potential energy calculations indicated a minimum speed at the collision point of approximately 24mph. Actual site measurements indicated speeds of approximately 38mph were easily attainable in the moments before the collision. These factors will be presented.

A number of interesting techniques were developed during the course of this investigation and will be presented. Site measurements during summer months are compared to winter views. Opposing expert topographic models are presented, along with a discussion of the importance of deposition testimony and perceptions of position and speed on a hill.

Actual test runs along the trajectories of the participants were documented through use of the GPS capability of an iPhone®, an app called Ski Tracks®, and recorded video on a GoPro® camera with surprising results that were then plotted on Google® Earth®. These novel products allow investigators a degree of flexibility not available only a few years ago.

The general case outcome will be discussed as will the importance of the orthographic photo techniques that set the stage for this case resolution.

D48 Reconstruction of a Seven-Car Pileup: A Case Study

John J. Smith, MSEE, PE, Raymond P. Smith & Associates, 43766 Buckskin Road, Parker, CO 80138; and Bradley Boville, BA, Raymond P. Smith & Associates, 43766 Buckskin Road, Parker, CO 80138*

After attending this presentation, attendees will understand the principles and techniques of reconstructing an accident with compound collisions and multiple vehicles, including momentum and energy analysis, restitution, and crush analysis. Other visual cues such as paint transfer and overlaid impacts were used to guide and confirm the results. These techniques were used to determine the closing speeds, time separating collisions, and change in velocity for a number of vehicles in a series of impacts.

This presentation will impact the forensic science community by showing how proper application of common techniques can yield valuable information to a reconstructionist and, when combined with readily available documents, can be used to analyze highly complex collisions. These same techniques can be used to determine vehicle-closing velocity and change in velocity, which will enable the reconstructionist to assign liability across a wide range of collision configurations.

The provided documents were typical of those in investigations with a legal component and included photographs of the vehicles and scene, accident reports for each set of collisions, and depositions of drivers and occupants. Combined with CARFAX® data, vehicle specification data, and scene and vehicle inspections, these documents provided the raw data for the reconstruction.

In this case study, a grass fire burned out of control resulting in thick smoke crossing a major highway. As a result, seven vehicles were involved in eleven discrete collisions. The involved vehicles were two tractor trailers, one pickup truck, two passenger vans, one Sport Utility Vehicle (SUV), and one car. Several vehicles were struck multiple times and moved from their resting positions in each collision. Reconstructing the event required analyzing not only the movement of each vehicle, but also the timing of the collisions relative to one another. As is often the case, many of the involved parties gave contradictory testimony, which was further complicated by the on-scene deaths of the two occupants in one of the vehicles. All but one of the vehicles was towed to the same storage lot, allowing the Highway Patrol to align the vehicles using a tow truck and compare crush profiles.

Each of the collisions was analyzed separately as a two- or three-vehicle event. After some collisions, the vehicles would come to rest before being impacted again, whereas others sustained multiple impacts without stopping. Passenger vehicles of several varieties and tractor semi-trailers were involved in these collisions. The reconstruction methodology presented can be used successfully in each of these situations.

Multi-Car, Accident Reconstruction, Passenger Vehicle

D49 3D Animation Applied to the Analysis of Pre-Impact Visibility Obscurement

Kurt D. Weiss, MS, Automotive Safety Research, 5350 Hollister Avenue, Ste D, Santa Barbara, CA 93111-2326*

The goal of this presentation is to illustrate the need for careful analysis of potential sight-line obscurements. While aerial and ground-based 2D still photographs may carefully document the available evidence used in collision analysis, 3D animation of the moving interaction fully illustrates the lack of objects that were suggested to have blocked potential advance warning of an impending collision hazard.

This presentation will impact the forensic science community by highlighting the benefits of 3D animation when used as a tool to accurately and clearly demonstrate driver visibility and sight lines. This case study evaluates a utility truck driver's sight line in the moments before a tragic collision that killed an adolescent bicyclist.

Driver detection and perception of roadside hazards and subsequent collision avoidance maneuvers are commonly evaluated in traffic accident-cause analysis. Tragedy often strikes when a traffic collision involves small children on bicycles. Collisions can occur when children suddenly ride into the roadway from between parked vehicles, giving alert drivers little if any time to avoid impending disaster. Likewise, inattentive drivers may have limited resources available to avoid similar tragedy. Collision analysis uses physical evidence to assist in the determination of cause; however, only after thorough evaluation of the available information can a correct conclusion be made.

A telephone repair technician in search of a customer's residence was driving his utility truck in an alley. The alley provides access to trash collection services and apartment building tenant parking. It is not uncommon for children to play nearby. The technician proceeded south at what he estimates was approximately 1mph-2mph, his foot resting on the brake pedal. After passing a few vehicles parked to his right, he heard a sound at the right front of his truck. He rolled forward another 33ft, stopped, and checked his mirrors. In the right side mirror, he observed a bicycle on the ground behind his truck. The fatal victim was a 6-year old girl who had just started riding the bicycle not more than 125ft away.

Law enforcement personnel secured the alleyway, marked and photographed the physical evidence, including the bicycle, utility truck, pavement, parked vehicles, a small circular gouge to the pavement, a 4.75ft-long tire friction mark, corresponding rear bicycle tire abrasion, and a rub mark to the outer sidewall of the utility truck's right front tire. The investigators determined that the child was riding the bicycle on a path between two apartment buildings toward the alley. After entering the alley and applying the coaster brake that locked the bicycle's rear tire, the child continued forward another 14ft and struck the utility truck. The rub mark was caused by the bicycle's front tire where it impacted the utility truck. The child then fell to the ground where she was subsequently run over by the right rear dually tires. The investigators concluded the utility truck speed was not excessive nor was a collision factor, but that the child failed to yield the right-of-way to alley traffic.

Careful forensic analysis of the conditions in the alley was used to determine the time during which the child was visible before impact. The alley was measured with a total station. Using photographs, the location of the parked vehicles, point of impact, and the tire friction mark, the child's trajectory on the bicycle was modeled using 3D software. The child's height (4ft, 8in) was found in the coroner's report. The child's speed between buildings (9.5mph) was approximated with surrogate testing of a similar bicycle in the alley. Her speed at impact after skidding on gravel/asphalt was 7.9mph. Truck speeds of 6mph and 10mph were used. Based on a time-position history analysis of the truck and bicyclist, two impact scenarios were animated. Two camera views were modeled, one from the perspective of the driver inside the utility truck cab and another overhead view tracking the forward progress of the truck leading toward the impact. At a truck speed of 6mph, the bicyclist was in view of the technician for 2.2-2.4sec. At 6mph and using a 1.5sec perception/reaction time, the technician had sufficient time and distance to stop his truck and avoid impact. At a truck speed of 10mph, the bicyclist was in view of the technician for 1.8-2.0sec. At 10mph and using a 1.5sec perception/reaction time, the technician had sufficient time and distance to slow his truck to avoid running over the bicyclist.

The results of the collision analysis highlighted with 3D animation show with graphic clarity the lack of timely response by the truck driver, who in one scenario could have completely avoided the impact, while in the other, after the bicyclist struck his truck, could have braked in time to avoid running over her.

D50 Engineering Ethics and an Aircraft Crash

William H. Muzzy III, BS, 1509 Porter Avenue, Ocean Springs, MS 39564*

After attending this presentation, attendees will understand that an engineering code of ethics should be a way of life for those practicing the art and science of engineering design. This presentation will show that engineers require sound judgment to interpret how the code would apply to specific circumstances. An example of an injury to a helicopter pilot during a crash that was due to failure to follow through on a recognized hazard will demonstrate the consequences of that failure.

This presentation will impact the forensic science community by educating the community of the need to know that commitment to serving society and attending to the welfare and progress of the majority has the highest priority. When there is a basic ethical dilemma, an engineer has a duty to report to the appropriate authority a possible risk to others from a client or employer failing to follow the engineer's directions. The obligation to report overrides the duty to a client and or employer.

A military helicopter was hovering on station in a combat zone waiting for the rest of the force to arrive when the main coupling between the engine and transmission failed. The crew conducted an autorotation landing resulting in injuries to both crew members. The pilot's injuries required extrication from the aircraft while his copilot was able to exit the aircraft without additional help. The pilot sustained a burst fracture of the L1 vertebral body with sudden onset of paraplegia and bowel and bladder dysfunction.

This military helicopter had been recently upgraded to include a larger engine, a six-blade prop, and new landing gear. This increased both its internal and external gross weight capacity. The design modification company that supplied the upgrade kit recommended that the government include a Voice Warning System (VWS) with the new engine although no location for the VWS was included in the modification drawings and specifications.

The purpose of occupant restraint systems in helicopter crashes is the protection of occupants to increase their probability of survival during crashes and hard landings. Another critical feature in modern helicopters is that seats are designed to reduce lumbar spine loading during hard landings by energy transfer during impact as referenced in the Federal Aviation Regulations (FAR) 14 CFR Section 27.561 and 562.

Each front seat was equipped with a five-point harness and a seat structure that consisted of a crushable box structure and a seat cushion. The crush box was designed to deform and attenuate the kinetic energy of the load as it moves over the stroking distance, thereby transferring the kinetic energy away from the passenger.

Space was limited within the aircraft cockpit so the installers placed the VWS within the crush box. This effectively placed a vertical beam between the top and bottom of the box and defeated its purpose. During an inspection of a test helicopter, the supplier of the upgrade kit verbally recommended to the military that the voice warning box not be located within the crush box structure. No written record was ever made of the conversation and no follow up was done.

This Code of Ethics was not followed by the modification kit supplier engineer in charge or other personnel present who had observed the dangerous installation location of the VWS in the test helicopter and did not take any steps to remedy the defective condition.

Alerting the intended users and purchasers of the helicopter of this dangerous condition is an expected industry standard, as is also the correction of the problem.

D51 Left-of-Center Accident Reconstructions: A Case Study

Darren Franck, MSME, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304; and Harold Franck, MSE, PE, Advanced Engineering Associates, Inc, 4713 MacCorkle Avenue, SE, Charleston, WV 25304*

After attending this presentation, attendees will understand the standard techniques used in reconstruction of left-of-center accidents on two-lane roads.

This presentation will impact the forensic science community by demonstrating the importance of a complete reconstruction of vehicular accidents when the at-fault party is in doubt.

This case study involves a frontal offset collision of a four-door sedan and a pick-up truck. Both vehicles contained one occupant and there were no independent witnesses to the accident. The accident occurred on a curved and sloping section of a two-lane asphalt road. The driver of the sedan was traveling downhill along a left-handed curve and was nearing the left turn into her neighborhood. The driver of the truck was traveling uphill and in the opposite direction. After colliding, the sedan was forced off the right side of the roadway and through a guardrail. The truck entered a yaw, rolled onto its passenger's side, and came to rest within the center of the roadway. The initial investigation revealed a gouge mark within the truck's lane of travel. Threats of criminal action against the driver of the sedan were made. Furthermore, the truck driver's insurance company proceeded to hire attorneys and accident reconstruction experts to bolster their case. Given the mounting evidence against their driver, the insurance carrier for the sedan was not willing to pay for their own expert. As such, the driver of the sedan was tasked with financing her own investigation.

Forensic experts became involved in the case shortly after the accident. Thus, the scene and vehicle evidence was maintained. The examination of the scene revealed a large body of evidence that seemed to refute the initial determination. This evidence included an initiation gouge near the white fog line of the sedan's lane of travel. Placing the impact point at this gouge mark indicates that the truck had crossed the center line. Damage to a utility box matched scrape marks along the passenger's side of the sedan. Moreover, initial momentum calculations seemed to confirm this hypothesis.

The opposing experts identified gouges and scrapes that crossed the center line. One of these gouges, which was located within the truck's lane of travel, was cited as the point of impact by the initial investigators; however, a closer examination revealed a similar gouge a few feet away. The two gouges exhibited curving features consistent with contact with rotating wheel rims. Moreover, the distance between the gouges matched the wheelbase of the truck. The truck examination revealed evidence of contact between the passenger's side wheel rims and the pavement. While the opposing parties attempted to attribute one of the two gouges to the collision, the physical evidence revealed that both gouges were produced during the post-impact phase of the truck.

Interrogation of the event data recorder provided the speed change magnitudes for each vehicle. Damage-based estimates for speed change were found to be consistent with this data. A detailed momentum analysis was performed based on the physical evidence, which demonstrated that the truck had crossed into the sedan's lane of travel prior to impact. This analysis yielded speed change magnitudes consistent with the crush analysis and event data. The computations indicate that the truck was exceeding the speed limit and traveling at three times the speed of the sedan. Given the disparity in speed and mass, the sedan was driven backwards from the point of impact to its rest position. The truck continued in its general direction after impact and eventually rolled onto its passenger side due to its post-impact yaw.

The opposing party maintained their view that the driver of the sedan was at fault. An alternative scenario was devised in an attempt to explain their position. This scenario placed the sedan within the truck's lane of travel at the point of impact. This impact was defined as the rim gouge located left of the center line. In order to maintain consistency with the established speed changes, the impact angles had to be adjusted for this alternate scenario. The approach angle for the truck was not probable given terrain bounding its side of the road. Moreover, this scenario failed to account for all the scene evidence, namely the rollover gouges, initiation gouge, and collateral damage to objects bounding the roadway.

Upon presenting the evidence in a written report, the opposing party decided to admit fault, which removed the specter of criminal action against the driver of the sedan. The successful results also permitted full financial compensation for this driver, who sustained significant injuries as a result of the accident. These results were only attainable by performing a complete reconstruction.

Left-of-Center, Conservation of Momentum, Rim Gouges

D52 Sideswipe Evidence for Traffic Accident Reconstruction

Russell L. Anderson, MS*, PO Box 7185, Tempe, AZ 85281

The goal of this presentation is to present physical evidence that can be found on vehicles involved in sideswipe accidents to assist in the reconstruction of these types of vehicle accidents.

This presentation will impact the forensic science community by presenting common physical evidence for accident reconstructionists and investigators to look for and by citing case studies showing how this evidence can be used to reconstruct sideswipe accidents.

It is commonly asked of traffic accident reconstructionists to determine how a sideswipe-type accident occurred. Although speeds of the vehicles are difficult to determine, common issues that are inquired about are which vehicle was overtaking the other and which vehicle turned into the other. In order to reconstruct a sideswipe accident, there is a plethora of common physical evidence that the investigator can look for.

Physical evidence including material flow, sheet metal deformation, pocketing, mirror rotation and damage, rubber transfer, and closing of body panel gaps are some examples of physical evidence that can show which vehicle was overtaking the other. Figure 1 depicts most of these examples from a sideswipe demonstration performed by researchers in which this vehicle was overtaking the other during the contact.

Figure 1: Typical sideswipe damage with side view mirror rotated rearward (overtaking vehicle).

Material flow can usually be found on plastic components such as door moldings, wheel opening moldings, and bumper covers. When the plastic component is contacted by the other vehicle, the plastic may be scraped and displaced toward the direction of contact. As shown in Figure 2, although located on the front bumper, the material flow from tire and rim contact was toward the driver's side, showing that the contacting vehicle was traveling from the passenger's side toward the driver's side during the contact.

Pocketing and sheet metal deformation occurs when the sheet metal is contacted with enough force to cause deformation. The force directed inward and forward by the overtaking vehicle can deform the sheet metal forward and can sometimes "pocket," indicating direction, as shown in Figure 3.

Figure 2: Material flow from vehicle passing from passenger's to driver's side.

Figure 3: Sheet metal deformation (left) and pocketing (right) showing force direction.

Mirror rotation and damage can occur when the side view mirror is contacted during the contact. Paint or plastic scuffing can usually be found on the leading edge of the mirror housing on the front or rear of the housing indicating which side of the mirror was contacted. The mirror is sometimes able to rotate, sometimes contacting the A-pillar, indicating direction. Figure 4 depicts mirror contact to an A-pillar from the mirror rotating forward from contact from an overtaking vehicle.

Figure 4: Mirror strike from forward rotating mirror housing.

Rubber Transfer can be indicative of tire contact. Figure 5 depicts examples of rubber transfer. The striations shown are evidence of contact with a spinning tire.

Figure 5: Examples of rubber transfer evidence.

Closing of body panel gaps can occur when the sheet metal is deformed and moved forward or rearward due to contact with the other vehicle. An example of a closed body panel gap is shown in Figure 6, where the left rear door panel was deformed rearward closing the gap.

Figure 6: Example of closing of body panel gaps.

Conclusions: In order to reconstruct a sideswipe accident, an accident reconstructionist can look for evidence including material flow, sheet metal deformation, pocketing, mirror rotation and damage, rubber transfer, and closing of body panel gaps.

D53 WISER: Automatically Classifying Written Statements as True or False

*Carole E. Chaski, PhD**, ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947; *Angela Almela, PhD*, Universidad Catolica de Murcia, Campus de Los Jerónimos, 135, 30107 Guadalupe, Murcia, SPAIN; *Gary Holness, PhD*, Delaware State University, Computer Science Dept, 1200 N Dupont Highway, Dover, DE 19901; and *Larry Barksdale, MA*, University of Nebraska, Forensic Science Dept, 211 Entomology Hall, Lincoln, NE 68583

After attending this presentation, attendees will better understand current approaches and results in computational classification of written statements as true or false. Attendees will be able to compare current and traditional approaches and evaluate methods on linguistic sophistication, psycholinguistic realism, accuracy, data requirements, and implementability.

This presentation will impact the forensic science community by providing measures of reliability to automated deception detection of written statements and an overall framework for investigators to evaluate different methods.

Witness Statement Evaluation Research (WISER) is a project using automated text analysis and statistical classifiers to determine the best protocol for computational classification of true and false statements in the forensic-investigative setting. In this research project, current and traditional approaches are being compared and tested and methods are being evaluated on linguistic sophistication, psycholinguistic realism, accuracy across different datasets, data quality requirements, and implementability. The most well-known and famous method for deception detection or veracity assessment is Sapir's Scientific Content Analysis (SCAN) described at a website and methods following it are generally known as statement analysis.¹ SCAN has been automated to a great degree with reported accuracy results of 71% by Fitzpatrick and Bachenko on a dataset that has not been made available to the WISER project.² Another approach is Pennebaker's Linguistic Inquiry and Word Count (LIWC), a word count and categorization program that has been applied to authorship identification, gender and age estimation as well as deception, even though its original purpose and design was to classify writing samples into personality types for psychological assessment.³ A third approach that is popular among computer scientists working in text classification is the Bag Of Words (BOW) model, a term invented by Harris and developed by Salton and McGill in which each text is seen as a list of words and their frequencies without regard to any syntax, semantics, or grammatical relations.^{4,5} Both LIWC and BOW have been tested as deception detection methods by Almela and Mihalcea and Strapparava.^{6,7} A fourth approach is based in Text Analysis Toolkit Toward Linguistic Evidence Research (TATTLE), a text analysis tool; TATTLE combines linguistic analysis at the phonological, syntactic, and lexico-semantic levels and has been applied to deception detection classification on both experimental and high-stakes datasets.^{8,9} The TATTLE results showed a remarkable difference between the experimental data, in which students were asked to write two narratives of a traumatic experience, one truthful and the other false, and high-stakes data, actual statements from real criminal investigations with non-linguistic evidence of their veracity or falsehood. Using the same TATTLE algorithm, the texts in the experimental data were correctly classified using leave-one-out cross-validation 71% of the time, while the texts in the high stakes data were correctly classified using leave-one-out cross-validation 93% of the time.

This result demonstrates that there is a real difference between lies told in an experimental setting (i.e., in a classroom as part of a class assignment) and lies told in a police investigation. Further, this result demonstrates that linguistic sophistication may be needed to develop highly reliable linguistic variables. Moreover, this result demonstrates that different statistical approaches which may work better with different linguistic variable sets (e.g., Support Vector Machine or Discriminant Function Analysis) may fit better with TATTLE variables than with LIWC or BOW. In this presentation, the results of testing the text-analytic linguistic variables from LIWC, BOW, and TATTLE using several different statistical approaches such as Discriminant Function Analysis, Support Vector Machine, and others, on three different datasets (experimental from the classroom setting on trauma narratives; experimental from an electronic venue for opinion mining; and, high-stakes data from real case investigations) are reported. Further, the methods on linguistic sophistication, psycholinguistic realism, accuracy over different datasets, data quality and quantity requirements, and implementability within the investigative, interview and interrogation workflow are evaluated.

D54 The Scientific and Legal Status of Forensic Speaker Recognition in the United States

*James L. Wayman, PhD**, San Jose State University, Office of Graduate Studies and Research, MS 0025, San Jose, CA 95192-0025; *William C. Thompson, PhD, JD*, University of California, Dept of Criminology, Law & Society, Irvine, CA 92697; and *Dorothy J. Glancy, JD*, Santa Clara University, School of Law, 500 El Camino Real, Santa Clara, CA 95053

The goal of this presentation is to provide a tutorial on the current state of forensic speaker recognition with an update on Overseas Security Advisory Council (OSAC) activities in this area.

This presentation will impact the forensic science community by discussing ways to improve the introduction and acceptance of new technologies for speaker recognition in American courts.

The use of scientific techniques to identify the speaker in an audio recording has a long and mixed history in American courts. An early non-digital methodology from the 1940s, known as “visible speech,” created spectrographic, pictorial representations of speaking patterns, which were compared by humans to determine if a graphical pattern from an unknown source could have come from a known speaker. Re-christened as “voiceprinting” in the early 1960s, testimony based on this graphical, spectral analysis method was admitted by a number of courts under the Frye standard, which requires that the method has attained “general acceptance in the particular field in which it belongs;” however, in subsequent decades, critiques of voiceprinting (including two influential reports by the National Academy of Sciences) caused the method to fall out of favor in the general scientific community, although cases admitting such evidence continued to be cited as legal precedent. Graphical spectral analysis (voiceprinting) has now been widely discarded in favor of two alternative approaches to speaker recognition, both with a lengthy scientific history: Automated (computer-based) Speaker Recognition (ASR) and human examiner-based aural perceptual (or “structured listening”) techniques.

In *Daubert v. Merrell Dow Pharmaceuticals* (1993), the United States Supreme Court adopted a new standard for the admissibility of scientific evidence in federal courts — a standard that requires the trial judge to assess the scientific basis of the testimony. In its discussion of factors judges should consider, the Court referred to two cases involving expert testimony based on voiceprints — *United States v. Williams* (CA2 1978) (concerning the importance of standards regarding the implementation of a scientific technique) and *United States v. Smith* (CA7 1989) (on the relevance of the known or potential rate of error of a particular scientific methodology). The Court’s reference to voiceprint testimony as exemplars of desirable features of scientific evidence is ironic, given that voiceprints, even when generated by digital technology, are no longer generally accepted by the relevant scientific community.

In the high-profile 2013 case of *State of Florida v. George Zimmerman*, the trial court referenced the accepted but outdated precedent on the admissibility of graphical spectral analysis (voiceprints) in denying admittance of highly problematic expert testimony based on automated speaker recognition, stating that “aural perception and spectral analysis have been widely used for many years and are sufficiently established to have gained general acceptance within the scientific community,” but that automated speaker recognition proffered is “not as widely accepted at this time.” This case well illustrates the difficulties that arise when evidence from evolving scientific fields like speaker recognition enters the legal system.

This presentation will review the technical basis and legal status of these three techniques for speaker recognition: (1) graphical spectral analysis (voiceprints); (2) automated (computer-based) speaker recognition (ASR); and; (3) human examiner-based aural perceptual (or “structured listening”) techniques. An important continuing speaker recognition test program conducted by the National Institute of Standards and Technology (NIST) and the activities of the Scientific Working Group for Forensic and Investigatory Speaker Recognition, created in 2012 with a broad agenda to support scientific, technical, and legal advancements, including an acknowledgement of privacy concerns will be discussed. (In late 2014, that group was reorganized as a sub-committee under the new Organization of Scientific Area Committees (OSAC) structure). This presentation will conclude with a broad discussion of ways to improve the introduction and acceptance of new technologies for speaker recognition in American courts that avoid muddling 21st-century scientific methodologies for speaker recognition with the now-discredited field of voiceprinting.

Speaker Recognition, OSAC, Florida vs. Zimmerman

Engineering Sciences Section - 2015

D55 Comparing Statistical and Machine-Learning Techniques in Author Identification and Verification

*Carole E. Chaski, PhD**, ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947; *Gary Holness, PhD*, Delaware State University, Computer Science Dept, 1200 N Dupont Highway, Dover, DE 19901; and *Michael J. Harris, MA*, University of California Santa Barbara, Dept of Spanish and Portuguese, Phelps Hall 4206, Santa Barbara, CA 93106

After attending this presentation, attendees will be acquainted with validation testing in forensic linguistic evidence, specifically author identification and current results of litigation-independent research. Attendees will be able to assess any author-identification methods they encounter in light of current research results and standards.

This presentation will impact the forensic science community by providing an example of validation testing that tests both statistical and machine-learning classification methods and by providing current research on the reliability of computational forensic linguistic author identification and verification. These problems are becoming more important due to the internet.

This presentation focuses on validation testing of methods for determining the author of a document in the forensic setting using a traditional forensic methodology and a novel biometric methodology. As Chaski explains, there are three current approaches to forensic author identification: forensic stylistics, computational stylometry, and forensic computational linguistics.¹ Stylistics has its roots in handwriting identification; stylometry in computer science and digital humanities; and forensic computational linguistics in linguistic theory and computational linguistics. Among the many ways that these three approaches differ, the most important is the attitude and productivity of a litigation-independent validation testing program to determine error rates and standard operating protocols with data requirements. Currently, only the forensic computational linguistics approach carries on a validation testing program on forensically feasible data (i.e., experimentally collected data or actual known data from cases and investigations, where all the data is “ground truth” for the tested method). Traditionally, computational forensic linguistics has focused on using hard-to-imitate, low-salience features that are psychologically real and theoretically valid: these features are syntactic structures categorized in a particular way.² Further, this feature set has yielded high accuracy (94%-95%) for author identification in two different datasets, one experimentally collected and the other from case investigations. Currently, this methodology has been used for both identification and verification. When used for an identification, the method requires a “line-up” of suspect authors who are each tested pair-wise against each other, with the resulting statistical model used to classify the questioned document to one or the other. If there is a large group of suspects, a binomial test can then be used on the multiple pairwise classifications, but often there are only two suspects (for reasons related to the case outside any linguistic analysis and unknown to the forensic linguist). When used for a verification, the questioned document must be long enough that it can be split into segments and tested against the known suspect documents; although the discriminant function procedure forces the documents into two groups, a single author’s documents often cannot be distinguished into two groups.

Using this same feature set on different datasets, this study is testing traditional forensic methodology using a pairwise procedure to determine levels of accuracy and data quantity with both statistical and machine learning classifiers. Thus the current experiments are testing if previous results using discriminant function analysis can be replicated at the 94%-95% accuracy with other statistical classifiers such as logistic regression. Further, the current experiments also test if machine learning classifiers like Support Vector Machine can attain even higher accuracy.

Again using the same feature set on different datasets, this study is also testing a novel biometric methodology to determine if this feature set can be used for verification. Distance and similarity matrices are being used with threshold settings to see how well this feature set performs as a verification metric. Further, a Bayesian analysis is being tested to see if both identification and verification protocols in this framework can be conducted.

D56 Comparing Literary, Biometric, and Forensic Approaches to Author Identification

Carole E. Chaski, PhD, ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947*

After attending this presentation, attendees will understand how to distinguish among the literary, biometric, and forensic approaches to linguistic evidence. Attendees will learn about the four corners of linguistic evidence and how the biometric approach relates to two of these four broad areas. After the presentation, attendees will be able to assess methods and their suitability for use in case investigations and trials.

This presentation will impact the forensic science community by providing a framework for assessing literary, biometric, and forensic approaches to linguistic evidence and how these lessons can be generalized to other forensic disciplines.

Linguistic evidence is evidence in a criminal or civil investigation that hinges on language itself to determine an element of the crime or civil action, such as the authorship of a threatening letter or the speaker of a bomb threat. Generally, linguistic evidence falls into one of four corners: identification, text-typing, intertextuality, and linguistic profiling. Two of these four corners illustrate the intersection of forensic and biometric approaches to linguistic evidence. Identification concerns both speaker (phonetic patterns) and author (lexico-syntactic patterns). Linguistic profiling concerns the sociolinguistic dimensions of language (e.g., age, gender, educational level, dialect, and associates an individual with a group identity).

In some recent high profile cases such as the J.K. Rowling pseudonym, literary author identification has been confused with forensic author identification. Author identification in the forensic setting is difficult and far more difficult than literary author identification for several reasons.¹⁻³ First, the language of forensic data is less sophisticated and more prone to ungrammaticality than literary language, so that automated parsers make far more mistakes on forensic data than on literary data. Second, the quantity of forensic data is usually much smaller than literary data, as forensic data might consist of tweets and other microtexts or emails while literary data can be tomes and novels. Third, in the forensic setting, the known and questioned documents come from different linguistic registers and genres, while literary data is consistently literary, all novels, all fiction, and all a literary register. These three differences mean that methods developed for the literary authorship question are not transferable to the forensic authorship question; however, the approaches can look similar to the public or to news reporters when the approaches both use computational tools.^{1,4} Hence, Chaski makes the distinction between computational stylometry and forensic computational linguistics.¹

A biometric is a measurement that uniquely identifies or individualizes a person by a biologically based characteristic or behavior. Language is biologically- and neurologically-based; the vocal tract and brain can be measured for unique characteristics. But language is typically seen as a behavioral biometric — it is the behavior of speaking or composing text that is proposed as the identifying and perhaps even individualizing characteristic. Behavioral biometrics are prone to intra-person variability, disguise, and imitation. The biometric and forensic approaches to individuality regarding face, iris, and fingerprint have been contrasted well by Geradts, Ruifrok, and Zoun; Houck and Seigal; and Vorder Bruegge, and these differences apply to author identification.⁵⁻⁷ The forensic author identification method developed by Chaski is influenced by the biometric approach because it is rooted in a biological/neurological conception of language, especially syntactic theory, and focused on behaviors that are almost impossible to disguise or imitate due to human memory constraints, but it is clearly within standard forensic methodology because it relies on a closed pool of extra-linguistically identified suspects — the line-up model for finding comparable knowns to which to match the questioned item.^{1,3,8} Further, like the biometric paradigm, the forensic author identification research conducted for this study is experimentally produced outside of any litigation in a proactive way and returns error rates for specific data quantities/qualities. But the biometric approach raises several research questions that are yet to be addressed adequately: Can author identification select an author in the wild, not in a lineup? Can a Bayesian approach solve this problem? How can error rates be calculated if results in the line-up model are 100% accurate, even under the dampening effect of leave-one-out cross-validation? While forensic author identification must be divorced from literary pursuits, the courtship with the biometric approach deserves a great deal of attention.

D57 Pathway for Integrating All Hazard Preparedness/Risk Management With Command and Control

*Robert Pentz, BS**, The Aerospace Corporation, 2350 E El Segundo Boulevard, El Segundo, CA 90245-4691; *Matthew Begert, BS**, 2350 E El Segundo Boulevard, El Segundo, CO 90245-4609; *Alan M. Foonberg, MS**, 2310 E El Segundo Boulevard, El Segundo, CA 90245; *Brendan J. Foran, PhD**, 2310 E El Segundo Boulevard, El Segundo, CA 90245; *Joseph Han, PhD**, The Aerospace Corporation, 2310 E El Segundo Boulevard, El Segundo, CA 90245; *Mark Polak, PhD**, The Aerospace Corporation, 2310 E El Segundo Boulevard, El Segundo, CA 90245; *Donald J. Rudy, PhD**, 3612 Barbara Street, San Pedro, CA 90731; and *Allyson D. Yarbrough, PhD**, The Aerospace Corporation, 2310 E El Segundo Boulevard, Mail Station M4/904, El Segundo, CA 90245

The goal of this presentation is for attendees to see a visual presentation of a systems engineering approach to providing security, safety, and quality of life as related to forensic enterprise.

This presentation will impact the forensic science community by encouraging them with examples for making better strategic and tactical decisions by the use of current and projected mapping capabilities along with their own common sense. It will expand the definition of mapping to include small-scale events, such as crime scenes, interiors and exteriors of buildings, and below-ground objects as well as those visible above ground.

Hazard and forensic preparedness is a fundamental aspect of individual, team, and community safety. Mapping is an integral part of this preparedness; however, no single individual, jurisdiction, or agency is expected or capable of performing every activity. This presentation will describe various types of forensic mapping (surface, above surface, and below surface), both static and dynamic, that deal with current and potential forensic activities.

Forensic maps should have several attributes in common. An earth-centered international coordinate system that allows a dynamic 3D analysis of potential and actual crime scenes is proposed. Also the maps should have an accurate time and date stamp.

While many maps are available, some were developed decades ago and need to be updated using government and commercial off-the-shelf tools; they need updating at least once a year. The maps should be easily prepared, easily analyzed by experts and the general public, and easily integrated with local needs. This presentation illustrates how, with urban and rural examples, 3D maps can be applied to planning scenarios and real-time forensics using the federal government's universal task list.

Technology for specific protection and prevention for those going into harm's way is not limited to the defense sector, which has extensive transferable technical expertise. Acknowledged engineering and scientific experts in geomapping and the forensic enterprise want to use their expertise and experience in a proactive role; by being multijurisdictional trusted agents and expert witnesses.

Results from working with architects, lawyers, judges, and developers, and examples of integrated local maps will be presented.

Maps, Security, Safety

D58 The Next Step: Creating and Using the 3D Working Model From Laser Scan Data to Better Seek and Illustrate the Truth

Craig T. Fries, BA, Precision Simulations, Inc, 115 S Church Street, Grass Valley, CA 95945*

After attending this presentation, attendees will better understand the 3D working model, 3D laser scanning, and their effective use in incident documentation, analysis, and visualization.

This presentation will impact the forensic science community by introducing a powerful and proven concept from traditional sciences to the forensic field. The 3D working model will facilitate the search for the truth by reducing conjecture and increasing fidelity to the physical evidence.

All phases of accident and crime reconstruction have been revolutionized by 3D laser scanning. The documentation of physical evidence is now so accurate and complete that experts can work directly with the 3D working model years after the fact as if they were working in the crime scene itself. Measuring millions of data points in mere minutes, a modern 3D laser scan is capable of capturing every inch of a scene with precision and detail sufficient to locate the smallest evidence. A typical scan contains approximately 10,000,000 data points — a level of detail akin to having the entire scene and all the physical evidence extracted and delivered to the expert's lab for thorough and exacting analytical forensics. Harnessing these rich datasets with the analytical power of modern computers allows unparalleled depth of analysis. From determining the velocity of vehicles involved in accidents, deriving critical values from video footage and scene photographs to exacting line-of-sight calculations and ballistic trajectory analysis, the 3D working model provides the expert with a toolset based upon physical evidence that was previously unavailable. The fastest growing areas of growth is the use of the 3D working model to analyze opposing expert's conclusions and opinions. Being able to plug the underlying assumptions back into the 3D working model allows the expert to determine how well, or not, the results match the physical evidence.

Once the dataset has been utilized to complete a thorough investigation and derive fact-based conclusions supported by the physical evidence, the final stage of the process also benefits greatly from the underlying 3D working model. The visualization of the dataset and the conclusions via 3D computer animation and simulation allows the experts to present their findings in a clear, compelling manner. Using the laser scan data directly in the visualization provides a level of realism and accuracy that far exceeds what was possible before. In addition to being visually compelling in its own right, the scan data gives the expert the opportunity to animate over the exact same dataset upon which their calculations were performed. This increases the accuracy of the final visualization, eliminating the need to resort to mere illustrations and elevating the animation to a true engineering visualization. This ability to maintain the highest level of scene fidelity increases the likelihood that the animation will be admitted into the trial setting and significantly helps combat the CSI-effect often seen in urban courtrooms. Today's juror comes to the trial with an expectation, born from television and other media, that the facts and findings will be presented in a visually compelling manner. The use of the 3D working model and 3D laser scanning in forensics in the United States will be demonstrated via compelling graphics and analyses in all three phases of the reconstruction process, pulling from 20 year's experience and more than 1,000 cases.

Laser Scanning, 3D Animation, Visualization

Engineering Sciences Section - 2015

D59 You View Your World in 3D — Shouldn't You View Your Case in the Same Manner? The Use of High-Definition Survey (HDS) Laser Scanning in Forensic Engineering

Steven M. Schorr, PE, DJS Associates, Inc, Forensic Engineering Services, 1603 Old York Road, Abington, PA 19001*

After attending the presentation, attendees will understand how 3D data is collected, how the data is processed, and most importantly, how the data is utilized in actual case examples of all types.

This presentation will impact the forensic science community by bringing to the forefront the benefits of the most accurate and comprehensive 3D data collection available — HDS laser scanning.

A far cry from just a few years ago when measurements on all cases were collected using rulers and rolling wheels, new technology has allowed engineers and others to quickly collect accurate, comprehensive data in 3D. HDS laser scanning has opened a whole new world for any engineer, scientist, or technical person who needs to collect accurate, comprehensive 3D data. HDS laser scanning can be utilized to collect data from vehicular collisions, fires, building collapses, slip-and-fall events, and any other type of case that warrants accurate measurements.

The HDS laser scans provide invaluable data for analysis purposes (especially when the data is collected soon after the events occurred). The HDS laser scan data also provides a foundation of data (collected with unparalleled comprehension and accuracy) to allow the expert, the attorney/client, and the trier of fact to view the events in a 3D environment. Commercially available software allows for the creation of a 3D “real-world” environment that allows one to view the event or scene from almost any orientation. For example, a 3D environment allows for: an evaluation of what a driver could see through his/her windows and mirrors as he approached and executed a turn; an evaluation of what a witness could see through a window or door; a pedestrian's view of a pavement irregularity as he/she approached; and/or, 3D views of products such as vehicles or machines.

This presentation will focus on the accuracy of the data, how to get the data into evidence, and the cost of this new, must-have technology.

High-Definition Survey (HDS), 3D Data Collection, Laser Scanning

D60 The Assessment of Facial Modifications Due to Mimicry: Possible Influences on Personal Identification From Video Surveillance Systems

*Daniele M. Gibelli, PhD**, LABANOF, Sezione di Medicina Legale, Dipartimento di Scienze Biomediche, per la Salute, V. Mangiagalli, 37, Milan 20133, ITALY; *Danilo De Angelis, DDS*, via Mangiagalli 37, Milan 20133, ITALY; *Pasquale Poppa, BS*, V. Mangiagalli, 37, Milan 20133, ITALY; *Federica Collini*, Via Mangiagalli 37, Milan 20133, ITALY; *Chiarella Sforza, MD*, V. Mangiagalli, 31, Milan 20133, ITALY; and *Cristina Cattaneo, PhD*, Universta Degli Studi Di Milano, Milan 20133, ITALY

After attending this presentation, attendees will better understand the facial modifications due to mimicry and their impact on the reliability of 3D/2D superimposition for personal identification from video surveillance systems.

This presentation will impact the forensic science community by providing clues for facial modification concerns that are due to different facial expressions.

More and more frequently, forensic anthropologists are requested by judicial authorities to assess personal identification from video surveillance systems: 3D/2D superimposition is one of the most commonly used methods which consists of the comparison between a 3D model obtained from the suspect through advanced 3D image acquisition technologies (laser scanner and stereophotogrammetry) and 2D images taken from the video surveillance records. Faces to compare are expected to be neutral, but the culprit may have different facial expressions which may add a bias to the 3D/2D superimposition, therefore resulting in an error in the identification process.

This presentation proposes to expose two pilot studies concerning the assessment of facial modifications due to different expressions.

In the first project, ten male adults, between 30 and 40 years of age, underwent five acquisitions by stereophotogrammetry (VECTRA-3D[®]) with different expressions (neutral, happy, sad, angry, surprised). On each 3D facial model, nine landmarks (right and left endocanthion; right and left exocanthion; right and left cheilion; on the midline, selion, pronasale, subnasale) were identified using VAM[®] software; the acquisition of each individual with happy, sad, angry, and surprised expressions was then superimposed onto the neutral one in order to reach the best match between the corresponding landmarks. This procedure allowed the operator to also obtain a chromatic sheet of the face, where increasing zones are colored in blue and the decreasing zones in red. In all the cases, the Root Mean Square (RMS) value between the two models was calculated as well.

In the second project, five photographs with different expressions (neutral, happy, sad, angry, surprised) were taken from five male adults chosen from the previous group; the 3D model in neutral expression was then superimposed to each photo and the distance between 12 facial landmarks (right and left endocanthion, right and left exocanthion, right and left cheilion, right and left alare, right and left gonion; on the midline, selion, pronasale) located on the 3D scan and the 2D images was estimated by Adobe[®] Photoshop[®] software.

The first study highlighted that the highest difference in comparison with the neutral standard was shown by the happy expression (mean RMS 4.11mm, SD 1.13mm), followed by the surprised expression (mean RMS 2.74mm, SD 1.02mm), the sad (mean RMS 1.3mm, SD 0.49mm), and angry (mean RMS 1.21mm, SD 0.37mm). The happy and surprised expressions showed a wide modification of the mouth, chin, and cheek regions, whereas the upper third of the face does not show relevant modifications. The sad and angry expressions were affected by slight alterations.

The second study confirmed that the highest mean differences between facial landmarks on 3D scan and 2D image was reached by the happy expression (0.17cm, SD: 0.35cm), followed by the surprised expression (0.08cm, SD: 0.19cm). The sad and angry expressions showed the lowest modifications (respectively, 0.07cm, SD: 0.2cm and 0.05, SD: 0.13cm).

This pilot study shows that mimicry affects facial morphological characteristics and the position of facial landmarks, and therefore may influence the outcome of 3D/2D superimposition procedures for identificative purposes: in addition, the study highlighted the facial regions more stable with mimicry and therefore more usable for a possible identification procedures. Further studies on a larger population are needed in order to provide more details of the phenomenon and possibly add corrective values for assessing personal identification from video surveillance systems.

Facial Mimicry, Stereophotogrammetry, Personal Identification

D61 Image Processing Application to Anthropological Automatic Characterization in Forensics

*Alberto L. Geraci**, Via Domenico Tempio 3, Acicastello, Catania 95021, ITALY; and *Giovanna A. Fargione, PhD*, University of Catania, Viale Andrea Doria 6, Catania 95125, ITALY

The goal of this presentation is to propose an automatic method of anthropometric data collection in forensics, making the process as automated as possible.

This presentation will impact the forensic science community by explaining the proposed procedure which was applied to anthropometric examinations performed on subjects whose photos were taken by security cameras in public places.

The goal of this work is the implementation of a software application that provides an automatic method of anthropometric data collection of an individual. In particular, it has created a tool that could detect human physiognomy information starting from a still image, taken from a movie by a security camera, using clear reliefs of sample objects taken at the scene of the crime.

The photo shows the objects on a flat surface and the illusion of depth is given solely from the perspective and chiaroscuro. It is therefore not immediately possible to detect the actual size of an object represented in a still image. The only method of obtaining this information is through direct confrontation with another item in the same creative whose size is known. Based on this principle, the proposed software application was produced. For this study, video recordings at the crime scene were viewed to capture an image that reflected the subject at full length, then a number of steps were performed, including the following: (1) identifying an item in the recording whose measurement is known or readily available, that can be used as a reference object; (2) carrying out a survey in order to detect the object reference measurements and any other useful elements for the same purpose; (3) highlighting inside the image points, which identifies the reference sample and the element to gain size perspective; and, (4) carrying out appropriate scaling operations, dictated by the rules of perspective, between actual measurements and those selected in the image. Based on the results, an anthropomorphic profile of the individual can be obtained.

Previously, it was already possible to perform all the above operations using manual methods to calculate all anthropometric data, minus a margin of error due to the tools and methods used for the measurement.

The proposed procedure was initially applied to an anthropometric examination performed on an armed subject, taken by security cameras in a public place. These pictures were used to finally conduct a functional testing of the software produced. The application that is described here will make the process the most automated possible, in such a way as to minimize measurement errors of an accidental and instrumental type.

Image Processing, Automatic Characterization, Software Implementation

E1 Use of Earprints as Evidence in Spain

Carlos J. Lopez-Gobernado, PhD, Cuerpo Nacional De Policia, 1 UIP XI Grupo Operativo, C/ La Tacona S/N, Madrid 28030, SPAIN*

After attending this presentation, attendees will be familiar with the concept of earprint and earmark evidence used by the Spanish Cuerpo Nacional de Policia (CNP), with how this evidence is collected and classified by technicians, and with how it is used as evidence in criminal courts.¹

This presentation will impact the forensic science community by implementing new ways to use earprints, applying a scientific method to classify them, showing the problems associated with the use of this technique, and pointing out the advantages that have helped police department investigations.

While numerous studies have looked into the various parts of the ear to classify earprints, the CNP uses a pattern to measure different parts of an earmark found at a crime scene, then records it in the database. With this classification, earprints obtained in the laboratory or earmarks found at other crime scenes can be compared. This comparison helps investigators eliminate suspects or open new investigative paths. There are open research areas that are attempting to demonstrate this technique's validity and statistical research has been performed to evaluate its accuracy.^{2,3}

This study demonstrates the pattern and how the technician uses it to obtain different points for measuring the earmark/earprint. The formula obtained will have five numerical values and one non-numerical value. With this formula, classification will indicate if the earmark or earprint was from a right or left ear.

Judicial sentences from Spanish criminal courts from 2000 to 2013 were studied and it was determined that earprints have been admitted as circumstantial evidence. Circumstantial evidence has been delineated by Spanish Supreme and Constitutional court jurisprudence and this evidence must meet this criteria in order to be effective. The cases where earprints were involved came primarily from CNP burglary investigations. Credible, reliable testimony from a forensic expert in a criminal case is essential and in the studied cases, the CNP experts proved the suspect was in/at the crime scene and that the earmarks left there, after comparison with earprints taken at the police laboratory, were from one of his/her ears. Another goal of this research is to discover if this evidence is legitimate for the Spanish courts or deemed as unreliable evidence.

The opinions or assertions contained herein are the private view of the author and are not to be construed as official or as reflecting the views of the Spanish Ministry of the Interior or Spanish Cuerpo Nacional de Policia.

Earprint, Evidence, Classification

E2 Differentiation of Human, Animal, and Synthetic Hair by ATR-FTIR Spectroscopy

Jeremy M. Manheim*, University at Albany, Sta, Dept of Chemistry, 1400 Washington Avenue, Albany, NY 12222; Kyle C. Doty, BS, 2165 Robinwood Avenue, Schenectady, NY 12306; Gregory McLaughlin, MS, 100 Manning Boulevard, Albany, NY 12203; and Igor K. Lednev, PhD, 1400 Washington Avenue, Albany, NY 12222

After attending this presentation, attendees will understand the current problems forensic hair analysis faces and how Attenuated Total Reflectance-Fourier Transform Infrared (ATR-FTIR) spectroscopy combined with chemometrics provides a faster, quantitative, and inexpensive method for hair identification.

This presentation will impact the forensic science community by demonstrating a method that is able to quantitatively identify a sample of hair as human with no false negative human assignments, using a non-destructive and rapid approach without the need for sample preparation or specialization.

Hair fibers are ubiquitous to every environment and are a common form of trace evidence found at crime scenes. The primary difficulty forensic examiners face after retrieving a hair sample is determining its origin: if it came from a human or an animal and, if human, what is the race, gender, and type of body hair (e.g., head, pubic, underarm, etc.). Currently, the methodology of microscopic examination of potential hair evidence is absent of statistical probability and is inherently subjective.¹ In the 2009 National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Path Forward*, it was concluded that there are no accepted statistics about the frequency with which certain hair characteristics are distributed within a population and that hair comparisons for individualization have no scientific support without nuclear DNA.² In early 2013, the Federal Bureau of Investigation (FBI) began a review of more than 2,000 convictions based on hair evidence.³ Of the first 310 cases, DNA analysis revealed that 72 of the convictions were grounded on faulty hair evidence.³ Despite its increasing popularity, the process of extracting DNA is costly, destructive, time consuming, and the majority of times is unsuccessful due to its degradation and absence from the hair.⁴ A method for determining the identity of an unknown fiber quickly, with a high degree of certainty, and eliminating examiner bias would be extremely useful and cost-effective for the field of forensic science.

ATR-FTIR spectroscopy is a technique rising in popularity for analytical and biological purposes. The attributes of ATR-FTIR spectroscopy are very attractive for forensics because of its rapid and non-destructive nature, its ease-of-use, and minimal-to-no-sample preparation. An infrared spectrum displays the vibrational characteristics of a sample based on the different absorption frequencies of the individual functional groups.⁵ The advantage of combining ATR-FTIR spectroscopy with chemometrics is its ability to enhance the selectivity of the instrument and create classification models.⁶ With the availability of portable ATR-FTIR instruments, there is the potential for on-field analysis of the identification of a single hair fiber.

This study demonstrates the ability to discriminate natural hair from a synthetic fiber and differentiate human hair from animal hair (i.e., dog and cat hairs) using chemometric modeling of ATR-FTIR spectroscopic data.⁷ Two Partial Least Squares Discriminant Analysis (PLSDA) models were constructed: one to differentiate natural hair fibers from a synthetic fiber (binary) and the second discriminating human hair from animal hair (species specific). Hair samples were collected from a synthetic wig and a diverse population of humans, dogs, and cats. Of the many variables that can influence the chemical make-up of hair (bleaching, waving, straightening, and extensive sunlight exposure), only chemically treated (i.e., dye, bleaching, etc.) hairs were excluded from this study.⁸ Both models were successful in differentiating these classes; synthetic hair was completely separated from natural hair in the binary approach and all human samples were correctly predicted as human in the species-specific model. An external validation, using untrained donors, resulted in zero false positive and false negative assignments for the human class; however, one of the five external dog samples, from a breed of dog not accounted for in the training dataset, was misclassified and all spectra were incorrectly predicted as cat.

Overall, this demonstrates the significance of the model's unique ability to quantitatively identify a sample of hair as human with a high degree of confidence. Most importantly, the method can be conducted without the need of a trained expert, is non-destructive, requires no sample preparation, and results in rapid identification, making it of ample importance to the field of forensic science.

ATR-FTIR Spectroscopy, Chemometrics, Hair

E3 From 20 to 12 in 42 Years: A Case of Inflated Age Estimation and the Role of Forensic Anthropology in Cold Case Investigations

Katie M. Rubin, MS, University of Florida, C.A. Pound Human Identification Laboratory, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610; and Joshua A. Mott, Volusia County Sheriff's Office, Crime Scene Unit, 1330 Indian Lake Road, Daytona Beach, FL 32124*

After attending this presentation, attendees will have a better understanding of the forensic anthropologist's ability to redirect 40 years of investigative efforts through routine analysis of human remains.

This presentation will impact the forensic science community by illustrating the utility of forensic anthropology in cold case investigations involving human remains that would not have originally fallen under the auspice of the forensic anthropologist. In particular, this presentation demonstrates the practical value of traditional forensic anthropology in scenarios where DNA analysis may be of limited investigative significance.

In May 1972, partially decomposed human remains were located in a pond near Daytona Beach, FL. An autopsy indicated that the victim was a White male, approximately 20 years old, and determined the manner of death to be homicide. In an effort to not only identify the victim but also to locate any witnesses or suspects, the Volusia County Sheriff's Office (VCSO) pursued leads generated from this autopsy report and evidence found at the scene. They sought the help of the media in publicizing descriptive information regarding the decedent and the crime, as known at the time, in order to identify the victim; however, their investigative efforts failed to yield an identification. The subject was interred as a John Doe and added to the list of unsolved cold cases. Over the next four decades, law enforcement focused all further identification efforts on a specific subset of the population — young, adult White males.

In 2013, John Doe was exhumed in order to obtain a DNA sample for analysis as part of continuing efforts to identify the decedent. The University of Florida C.A. Pound Human Identification Laboratory (CAPHIL) assisted in the exhumation and further performed an anthropological examination not previously conducted. As the casket was opened on-scene, the decedent's ankle was exposed; the distal tibial and fibular epiphyses were open. It was immediately clear that the assumptions of the investigation were false; the remains were not those of an adult. The VCSO was immediately notified that their decedent was significantly younger than reported and the remains were transported back to the CAPHIL for extensive analysis.

The precise age of John Doe was assessed using extent of epiphyseal closure, long bone length, and degree of dental development. Additionally, both a non-ossifying fibroma and an osteochondroma, two distinct pathologies associated with actively growing subadults, were found. It was determined that the decedent was 11 to 14 years old, and most likely 12 to 13 years old, at the time of death. The result of this study was the most significant change to the case since its origin in 1972. The anthropological findings changed the dynamics of the crime itself and served to all but nullify the previous 40 years of investigative efforts by law enforcement well before the DNA results could even be submitted. Indeed, given the limited number of nuclear DNA comparative samples available as of 1972 and the taphonomic condition of the remains, the DNA may yield little novel information.

While advancements in the ability to extract and analyze DNA and the development of comparative DNA databanks have revolutionized the field of human identification and provided numerous invaluable identifications of decedents, DNA's role in cold cases that predate the Combined DNA Index System (CODIS) may be more limited. An extended postmortem interval and poor preservation of the remains may limit analysts' abilities to extract usable nuclear or mitochondrial DNA. Nuclear exemplars are likely unavailable; mitochondrial exemplars may likewise be limited and typically require a prospective identification for direct comparison. Even in the absence of a database match, DNA analysis may provide information about the biological sex and ancestry of the decedent, but cannot provide information regarding age-at-death or numerous other identifying characteristics (e.g., stature, idiosyncratic morphology, life history traits, etc.).

In summary, cold cases are routinely being reopened due to advances in DNA analysis; however, the original assumptions implicit to cold case investigations are not always correct and DNA is not always capable of correcting these errors. When investigative entities reopen cold cases, DNA analysis should be conducted, but the unique value of forensic anthropology — even for cases that underwent full autopsy — cannot be overlooked.

Anthropology, Cold Case, Age Estimation

E4 A Study of Morphological and Metric Variations of the Human Ear — Applications in Personal Identification

*Kewal Krishan, PhD**, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160 014, INDIA; *Tanuj Kanchan, MD*, Dept of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; and *Swati Thakur, MSc*, Panjab University, Dept of Anthropology, Sector-14, Chandigarh, AB, INDIA

After attending this presentation, attendees will understand the significance of the variability of the human ear, which may help them in conducting further studies and in solving forensic cases usually encountered in airplane crashes, intentional mutilation and dismemberment, explosions, or other mass disasters.

This presentation will impact the forensic science community by presenting new information on the variability and uniqueness of the human ear in an Indian population and the usefulness of the human ear in personal identification.

In the past, many morphological and metric features of the human body have been used for personal identification in forensic examinations. Fingerprints, footprints, facial characteristics and features, iris, gait, teeth, bitemarks, gait pattern, lip prints, voice characteristics, and DNA fingerprinting from a variety of tissues of the human body have successfully been utilized in forensic situations as well as for identification of criminals. The human ear is another organ of the body which is unique to an individual. Like fingerprints and other individualistic characteristics of the human body, an ear retains certain individualistic characteristics which are unique due to variations in the anatomical structures of the external ear. In certain situations, where the dead body is recovered in dismembered or mutilated conditions, the shape, size, and individualistic features of a person's ears may be useful in identifying the deceased along with other identification characteristics of the human body. In the recent past, it has also been shown that, like the ear itself, the prints left by the human ear are also individualistic to an individual; the earprints can be left by the criminals/burglars while listening at the doors or windows of the target house. So looking at the value of the human ear in forensic identification, the objective of the present study was to study the morphological and metric characteristics of the human ear in a north Indian population. The sample for the present study is comprised of 90 males and 87 females ranging in age from 18 to 30 years of age taken from the upper reaches of Himachal Pradesh State in North India. The morphological characteristics such as overall shape of the ear, size and shape of the tragus, ear lobe, shape of helix, forms of Darwin's tubercle, and rare and special characteristics as well as congenital deformities were studied in all the subjects. To generate data for the metric characteristics, physiognomic ear length and physiognomic ear breadth were measured using standard landmarks.

The physiognomic ear length and breadth in males were found to be significantly larger than those of the females. The length and breadth measurements of the ear show bilateral variations, although they were statistically insignificant. The other findings of the study indicate that the oval-shaped ear was present among 40% of the males and 44.8% of the females in the study sample. The flat-shaped ear was the rarest variant, reported only among 1.1% of the males in the study. The other types of ear, such as the oblique, rectangular, round, and triangular, were found in both sexes. Bilateral asymmetry exists in regard to the shape of the ear. The size and shape of the tragus also vary with respect to the left and right sides as well in sexes. The ear lobe showed different characteristics in different individuals. In nearly half of the cases in both males and females, the ear lobe was found to be attached to the face; in many cases, it was free, and, in some, partially attached. The size and shape of the ear lobe also showed variations with respect to sides as well as sexes. The shape of the helix varies in individuals showing certain characteristics such as concave, rolled, flat and wide covering scapha, etc. The Darwin tubercle showed a variety of structures in both the left and right sides in both the sexes.

Personal Identification, Human Ear, Variations and Uniqueness

E5 A Pilot Study to Evaluate Baseline Quantities of Recovered Touch DNA From a Pistol and Ammunition

Maher Nouredine, PhD, 5687 Wolf Ridge Court, Oak Ridge, NC 27310; and James A. Bailey, PhD, Minnesota State University Mankato, 617 Chestnut Street, Wilmington, NC 28401*

After attending this presentation, attendees will be familiar with collecting touch DNA samples from a pistol and ammunition, the DNA profile results from different parts of the pistol, and interpretation of results.

This presentation will impact the forensic science community by describing a method of collecting touch DNA on a pistol and interpreting distribution of profiles on different parts of the pistol and on ten rounds of ammunition.

The recovery of DNA samples from firearms has proven invaluable in the course of forensic investigations, in large part due to improvements in DNA sample collection, preservation, processing, and result interpretation. Typically, this type of evidence yields a limited quantity of biological material containing DNA template from perspiration and epithelial cells, the source for “touch DNA” samples. The quantity of DNA recovered by swabbing can vary based on the frequency of handling and cleaning surfaces of firearms, types of cleaning oils and solvents, physiology of the handler, number of contributors, and downstream testing methods. This research was conducted to evaluate the baseline level of Short Tandem Repeat (STR) DNA that can be recovered from a pistol and cartridges.

A 9mm Smith & Wesson® Model 5906 pistol was handled by one right-handed owner/shooter. The pistol was fired and stored without cleaning for a period of two weeks before swabbing. The shooter removed ten 9mm full-metal jacketed cartridges from a new unopened box of American Eagle® ammunition, loaded a full magazine, then inserted the magazine into the pistol and ejected it. The pistol, full magazine, and the original ammunition box were collected and swabbed for DNA as follows: two swabs were collected from the ammunition box, one swab was collected from the outer cardboard package, and one swab was collected from the inner plastic case holding the cartridges. A total of five swabs were collected from the magazine’s right, back, left, front, and base sides; ten swabs were collected, one from each 9mm cartridge, ordered by sequence of insertion into the magazine. Finally, 19 swabs were collected from the 9mm pistol to cover right side surfaces, left side surfaces, top surfaces, and specific parts of the pistol such as the trigger, trigger guard, and hammer. All samples and appropriate controls were collected using the COPAN® Crime Scene 4N6 FLOQSwabs™ that were pre-wetted with sterile water. DNA samples were extracted using the COPAN® Nucleic Acids Optimizers (NAO), a semi-permeable basket which retains fluid until centrifuged with the PrepFiler® Express™ on the *AutoMate Express™* DNA Extraction System by Life Technologies™. DNA quantitation was performed using the Quantifiler® Human DNA Quantification Kit by Life Technologies™. The AmpFLSTR® Identifier® Plus PCR Amplification Kit by Life Technologies™ was used for DNA amplification, the fragments were run on the Applied Biosystems™ 3130 Genetic Analyzer by Life Technologies™, and the analysis was performed with GeneMapper® ID-X v1.4.

The results show full STR profiles from the user on the cartridge box (one of two swabs), magazine (four out of five swabs), and various areas on the pistol (12 out of 19 swabs). Even though this shooter was right handed, a complete DNA profile was obtained on the right side of the pistol safety lever. Characteristically, a right-hand shooter manipulates an ambidextrous safety on the left side of the pistol; however, possibly in this case, the DNA on the right safety lever originated from the method of retracting the slide on the pistol. The shooter retracted the pistol slide by placing the left thumb on the right side of the slide over the safety lever with the index finger contacting the safety lever on the left side of the slide. Consequently, a DNA profile on one side of an ambidextrous safety does not indicate the shooter’s handedness. All swabs from the 9mm cartridges resulted in partial STR profiles with no direct correlation to the number of markers compared to the loading order of the cartridges in the magazine. This data can aid criminal investigators in assessing the probative value of DNA evidence recovered from specific parts of a pistol.

Touch DNA, DNA on Pistol, Swab From Firearm

E6 Mummified Tattoo Rehydration, Photography, and Reconstruction in Cold Case Investigations

Meredith L. Tise, PhD*, University of Lincoln, School of Life Sciences, Brayford Pool, Lincoln LN6 7TS, UNITED KINGDOM; David C. Boyer, MA, Pasco County Sheriff's Office, 36409 State Road 52, Dade City, FL 33525; and Melanie S. Linton-Smith, BA, Pasco County Sheriff's Office, 36409 State Road 52, Dade City, FL 33525

After attending this presentation, attendees will be familiar with the procedures conducted by the Pasco County Sheriff's Office in Pasco County, FL, on a small amount of mummified tissue in order to rehydrate, clean, and expose the details of a colored tattoo on a skeletonized cold case from 1989. This protocol allowed for effective photography using various color filters to expose the details and color of the tattoos to aid in the process of identification.

This presentation will impact the forensic science community by offering details into the successful process used on a small amount of mummified tissue recovered with skeletal remains. The process allowed for the exposure, reconstruction, photography, and preservation of tattoos, which has the potential to significantly improve case solvability for highly decomposed or skeletonized remains.

On January 24, 1989, the skeletal remains of an individual were found in an orange grove in Dade City, FL. The individual has remained unidentified and, in 2007, new efforts were initiated to further investigate the case in an attempt to make an identification. The skeletal remains were sent to the University of South Florida Forensic Anthropology Laboratory for a skeletal analysis to estimate the biological profile, and forensic investigators at the Pasco County Sheriff's Office began working with a small piece of mummified tissue found with the remains. The initial police report in 1989 stated that the tattoo on the mummified skin was "what appeared to be a rose with green leaves, purple stripes going from the rose to an area that resembles a spider web colored in yellow and black lines;" however, no efforts had been made at the time to clean or rehydrate the tissue.

After the tissue was rehydrated with a 50/50 glycerin and water solution in 2007, Pasco County Sheriff's Office forensic investigators cleaned the still-submerged tissue with sterile swabs. Prior to and after rehydration, the exposed tattoos on the tissue were thoroughly photographed using colored light filters at different nanometers (including red, orange, yellow, green and blue light filters, each at 450, 485, 530, and 570 nanometers) to visualize the different aspects and colors of the tattoos. These photographic techniques allowed for the reconstruction of very detailed and colored tattoo images that were very different from the original police description, including a bicep tattoo containing the initials "HFD," wings, flames, a cross, a rebel flag and swastika, as well as a forearm sleeve tattoo of a green flaming dragon winding down the arm around a nude female with red high heels on a rebel flag background. These updated details and images were included in the law enforcement agency bulletins and media releases.

This case is an excellent example of the use of innovative forensic techniques employed by the Pasco County Sheriff's Office that allowed the details of the preserved tattoo to be exposed and reconstructed almost 20 years after the remains were recovered. A limited amount of research has been published regarding the use of various imaging techniques to visualize tattoos on cadavers; however, most of these publications involve fresh cadavers where rehydration and cleaning is not necessary.¹⁻³ This presentation clearly outlines the protocol performed on the mummified tissue which can aid forensic investigators with other law enforcement agencies or medical examiner's offices if presented with similar mummified tissue that may have the potential to contain tattoos. By having the opportunity to update the tattoo description with clear photographs and reconstructions, the visibility and solvability of an unidentified cold case in law enforcement investigations, as well as mass disaster situations or human rights recoveries, will be dramatically increased.

E7 Carbon Monoxide Poisoning: A Study of Five Cases and Literature Review

Renata S. Razaboni, Doctor Mario Vicente Avenue, 1007 Ipiranga., Sao Paulo 04270-001, BRAZIL; Ivan D. Miziara, MD, PhD*, Rua Teodoro Sampaio, 352-22, Sao Paulo 05406000, BRAZIL; Carmen Silvia M. Miziara, MD, PhD, Rua Capote Valente, 127/111, Sao Paulo 05409000, BRAZIL; and Daniel R. Muñoz, MD, PhD, Rua Teodoro Sampaio, 155, São Paulo 05406000, BRAZIL

The goal of this presentation is to highlight the importance of coloration of the hypostases in suspected carbon monoxide poisoning and the importance of quantitative measurement of Carboxyhemoglobin (COHb) in the diagnosis of the cause of death.

This presentation will impact the forensic science community by providing results from a study of five cases of carbon monoxide intoxication and a literature review of carbon monoxide poisoning. This presentation is also an alert to medical examiners of the importance of hypostases coloration in the diagnosis of Carbon Monoxide (CO) poisoning.

CO is the leading cause of poisoning death in the world.¹ CO has a high affinity for hemoglobin, decreasing its ability to carry oxygen, causing hypoxia tissular.² At necropsy, there is blood fluidity, clear hypostases, and the organs have a red carmine color.³

This study presents five cases of death due to CO poisoning. The diagnosis was confirmed by autopsy in the Central Forensic Institute of Sao Paulo and the quantitative laboratory measurement of COHb was performed by spectrophotometry at the Oscar Freire Institute Department of Toxicology. A review was made of the literature regarding the signs and symptoms of this type of poisoning, as well as COHb values found in other studies. The review used complete studies, using MEDLINE® data from 2009 to 2014, published in English and Portuguese.

The five autopsies were from the same family, but were not performed simultaneously. The first one happened approximately 30 days before the other four; cause of death was unknown, despite a highly suggestive hypostases of CO poisoning. Later, four more necropsies of this same family came to light. Due to the arrival of four more bodies of this same family, with the same descriptive characteristics, CO poisoning was suspected. Laboratory tests showed the qualitative dosage of COHb was positive and the quantitative dosages were 84%, 88%, 94%, 87%, and 88%. Death may occur with COHb concentrations above 30%.⁴ Carbon monoxide is colorless, odorless, tasteless, and invisible, features that make this agent imperceptible to an exposed person. The main cause of death due to CO poisoning occurs in fires where the release of gases is due to the combustion of fuel or from defective heaters. Local expertise revealed that the source of emission of carbon monoxide was a gas heater located in the service area of the residence.

In order to suspect CO poisoning, the coroner must be aware that there are cases in which the main symptom, if not the only one, is the red carmine color that the hypostases acquire. Therefore, while performing a necropsy, the hypostases should be evaluated for their existence and location but, most importantly, for their color.

Carbon Monoxide Poisoning, Carbon Monoxide Intoxication, Death

E8 Does Probing Enhance the Decomposition Odor Released From a Gravesite?

Shari Forbes, PhD*, University of Technology Sydney, PO Box 123, Broadway, NSW 2007, AUSTRALIA; Amanda Troobnikoff, BSc, University of Technology Sydney, PO Box 123, Broadway 2007, AUSTRALIA; Katelynn A. Perrault, BSc, University of Technology Sydney, PO Box 123, Broadway 2007, AUSTRALIA; and Maiken Ueland, BSc, University of Technology Sydney, PO Box 123, Broadway 2007, AUSTRALIA

After attending this presentation, attendees will understand the impact of probing a gravesite with respect to the release of decomposition odor and its subsequent detection by Human Remains Detection (HRD) dogs.

This presentation will impact the forensic science community by expanding the general knowledge base relating to the decomposition odor profile of buried remains. The information will be valuable to law enforcement agencies who utilize HRD dogs to locate buried remains as it demonstrates the abundance of decomposition odor available at the grave surface and the impact of probing in releasing the odor for detection.

HRD dogs are trained to locate and respond to the odor produced by decomposed remains. The odor consists of a diverse range of Volatile Organic Compounds (VOCs) which are released into the atmosphere as the body decomposes over time. The concealment of a body in a gravesite will slow the decomposition rate and reduce the odor at the grave surface, proving a considerable challenge for HRD dogs tasked with locating buried remains. HRD handlers will often probe the ground surrounding a suspected gravesite with the intent of venting the soil to release the odor; however, due to its potential to damage remains sub-surface, the soil probe is typically used with caution. Damage to the remains can cause challenges for the medical examiner in determining whether the trauma occurred during the antemortem, peri-mortem, or postmortem period. Hence, the goal of this study was to determine whether probing offered any benefit to search investigations involving HRD dogs by releasing decomposition VOCs and enhancing their detection at the grave surface.

Pig carcasses (*Sus scrofa domestica*) were used as human decomposition analogues. Carcasses were buried in shallow graves to a depth of approximately 60cm. Control graves were established in close proximity to monitor the natural VOC profiles of the soil and vegetation without the presence of a carcass. The decomposition odor within the gravesites was monitored by placing a VOC sample collection tube permanently in the center of the graves. This provided a reference VOC profile throughout the decomposition period which could be compared to the VOCs detected at the grave surface. A stainless steel hood was placed over the surface of the graves prior to probing to allow the VOCs to accumulate. VOC samples were collected onto sorbent tubes and subsequently analyzed by thermal desorption — comprehensive Two-Dimensional-Gas Chromatography/Time-Of-Flight/Mass Spectrometry (TD-GC×GC/TOF/MS). This process was repeated after probing to determine whether the probe released additional VOCs that were not previously detected at the grave surface. Temperature data loggers were used to determine grave temperatures at the middle and base of the graves and a weather station was utilized to monitor environmental conditions at the site.

Comparison of the experimental and control sites allowed a list of VOCs to be identified within the grave and at the grave surface that were specific to the decomposition process. Over the eight-month study, more than 100 decomposition VOCs were detected within the grave but fewer were found at the grave surface. The abundance of VOCs at the grave surface peaked during early decomposition before quickly declining, suggesting that the soil texture can play a large role in the migration of VOCs to the grave surface. The profile detected at the grave surface did not always reflect the profile within the grave, supporting the ability of the soil microbial community to modify VOCs in the soil column. Some variability was seen in the grave surface samples collected before and after probing, which is likely attributed to the dynamic sampling environment, an important aspect to consider in search and recovery investigations. The benefits of probing should not be disregarded as on several of the sampling days, the air samples collected after probing displayed a greater abundance and more diverse profile of decomposition VOCs.

Decomposition Odor, Probing, Human Remains Detection Dogs

E9 Hammercide: A Bloody Hammer, a Dead Husband, a Bloody Wife, and a Bloody Live-In Friend, as Well as a False Confession

Steven E. McGibbon, MFS, PO Box 8204, Chandler, AZ 85246-8204; and Michael Bishop, BS*, Gilbert Police Department, 75 E Civic Center Drive, Gilbert, AZ 85296*

After attending this presentation, attendees will understand the complexity of having an individual trying to claim responsibility for a homicide they did not commit. Attendees will see how the forensic evidence will help to determine the truth.

This presentation will impact the forensic science community by exemplifying the use of different forensic disciplines that were necessary to arrest and prosecute the proper individual involved in a violent homicide when two people confessed.

In the early morning hours of January 14, 2009, the Gilbert, AZ, police department responded to a call from a local residence. Upon arrival, the first officer found a female outside with blood in her hair and on her clothing. Inside, the officer found a male (the victim) on the floor lying in a pool of blood as well as another male with blood on his clothing. There were also two young children asleep in the house.

The injured male was taken to an area hospital in extremely critical condition. Chance of survival was minimal despite state-of-the-art medical intervention at a major trauma center. The female (Suspect 1) at the scene was the spouse of the injured party. The other male (Suspect 2) was a live-in “friend of the family.”

Evidence at the scene and injuries to the victim indicated blunt force trauma. A bloody hammer on a table at the scene appeared to be the weapon used on the victim. It was time to put the pieces of the crime scene together based on forensic evidence as well as suspect and/or witness statements. Expectations were that certain forensic evidence should or could yield valuable types of information.

Suspect 2 stated that he beat the victim and was the one responsible for the carnage at the crime scene. Suspect 1 told police that Suspect 2 saved her as she was being raped by her husband. As Suspect 1’s story was proven inaccurate based on evidence at the scene, she changed her story and admitted she was the one who beat her husband with the hammer. She said she beat her husband with the hammer because he was an abusive husband and he raped her earlier in the evening. Suspect 2 made numerous efforts to confess and take blame for the crime, including going to a newspaper and another police department to confess. The confession of either Subject 1 or Subject 2 was false and the evidence was what would contradict or support the confessions.

In this case, like many others, the forensic evidence should provide valuable information as to what occurred and who committed this crime. With two people confessing to the crime, which became murder three weeks later when the victim died, the evidence needed to be carefully evaluated. What was expected from the evidence and what the evidence yielded was not as simple as sending items to a lab and getting the positive results one was expecting.

This presentation will describe the forensic evidence, what was expected from the evidence, what the results were, and, more importantly, how the evidence was used to prove or disprove the confessions of the two people taking the blame.

False Confession, Bloody Hammer, Live-In Friend

E10 Development Process Validation for Kinship Analysis Algorithm

Sharada Vijaychander, MS, Thermo Fisher Scientific, 180-120 Oyster Point Boulevard, South San Francisco, CA 94080*

After attending this presentation, attendees will gain an understanding of the established Life Technologies™ (LT) kinship algorithm analysis program, its features, flexible implementation, and standard calculations for trio analysis, including complex pedigree trees such as incest, motherless/fatherless cases, and inclusion/exclusion of mutations, and rare alleles based on currently used methods. The analysis program has established processes for Short Tandem Repeat (STR) analysis but a feasibility study using Single Nucleotide Polymorphism (SNP) data has also been proven.

This presentation will impact the forensic science community by not only using a standardized approach but will also show the ability to include concepts of both STRs and SNPs for better discrimination power.

Computing likelihood ratio in kinship analysis for autosomal markers is straightforward and well defined. Such calculation provides a value for evidence given the prosecution-versus-the-defense proposition. It is recommended and widely used in forensics, missing persons cases, and paternity cases. The forensics community has validated stand-alone software for calculating Likelihood Ratio (LR) using trios and many biologically related family members. Software such as Familias and MPKin™ FS Edition are used regularly for such calculations.¹⁻³ Because these implementations are stand-alone, transcription errors can occur on transferring data from data collection, table input, and result storage; in addition, it can also be time consuming.

LT has incorporated its version of a kinship algorithm, based on the Error Standard (ES) algorithm, to data collection and storage for ease of use and reliability of results, therefore avoiding human transcription errors.²⁻⁵ This presentation will encompass the steps taken by this study to validate the kinship analysis algorithm, given the available methods, data, and external collaborators. Building on previous literature, this study used the National Institute of Standards and Technology (NIST), the Council on Education for Public Health (CEPH), and real data from collaborators to compare results of the kinship algorithm to those currently used in the paternity and forensics laboratories. This study shows that the standard calculations, including complex pedigree trees, mutations, and rare alleles concur with currently used methods.

Through this work, the LT-kinship algorithm, a more flexible implementation with state-of-the-art models, has been established as accurate. The algorithm with SNP data has been further tested, showing that, for a small number of SNPs, the algorithm produces LR values, which may be an option once expert data and tables become available.

For Research, Forensic, or Paternity Use Only. Not for use in diagnostic procedures.

Kinship Algorithm, STRs, SNPs

E11 An Assessment of the Volatile Organic Compounds (VOCs) of an Agricultural Biothreat Agent, *Raffaelea lauricola*, and Training Aids for Canine Detection

*Alison Simon**, 555 NE 15th Street, #407, Miami, FL 33132; *Julian L. Mendel, MSc*, 10005 SW 141 Court, Miami, FL 33186; *Kenneth G. Furton, PhD*, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199; and *DeEtta Mills, PhD*, Florida International University, OE 167, Biological Sciences, 11200 SW 8th Street, Miami, FL 33199

After attending this presentation, attendees will learn about an agricultural biothreat agent known as the laurel wilt pathogen. Attendees will gain an understanding of how research is combatting the spread of this biothreat by analyzing the Volatile Organic Compounds (VOCs) present in the headspace above the fungus in order to create a mimic training aid to be used in canine detection.

This presentation will impact the forensic science community by presenting a novel method of preventing the spread of a biothreat through canine detection. It will also strengthen the validity of canine detection as it is currently used in the fields of forensics and agriculture by showing the canines' ability to detect biothreats and distinguish diseased trees from uninfected ones.

Invasive biological agents pose a huge threat to the agriculture, environment, and economy of the United States. These biothreats can enter the United States through ports-of-entry accidentally, as is the case of the invasive and phytopathogenic fungus *Raffaelea lauricola*. The current research identified the VOCs of the laurel wilt pathogen in order to create a mimic training aid. Using this aid, canines can be trained to detect infected trees before physical symptoms develop so that infected trees can be removed from groves and healthy trees protected. The vector of the *Raffaelea lauricola* fungus is the invasive redbay ambrosia beetle (*Xyleborus glabratus*), which entered the United States from Southeast Asia on infected wood. The symbiosis between the beetle and the fungus is a relationship where the beetle carries the fungus to a tree, bores into the host tree, and farms the fungus for food. The fungus colonizes the xylem of the tree, which then causes the tree to systematically shut down its transpiration mechanism in order to stem the spread of the infection. This leads to the tree's death within four to six weeks. Symptoms include wilting of the leaves and discoloration in the bark. Laurel wilt is advancing through the Lauraceae forests in the southeastern United States, and now is found in commercial avocado groves in Florida.

Because of the rate of advancement of the disease, a method of detection before the development of physical symptoms must be developed. Canines are often used in law enforcement and in ports-of-entry to prevent the entry of substances such as known biothreats or banned agricultural items; however, novel biothreats such as *Raffaelea lauricola* have not been stopped at the port-of-entry and are now spreading through the forests and agricultural environments. The current study focuses on identifying the VOCs above the laurel wilt pathogen in infected trees through Solid Phase Microextraction/Gas Chromatography/Mass Spectrometry (SPME/GC/MS). The goal is to create a biological mimic with which to train canines to locate the pathogen in avocado groves so the diseased trees can be removed and healthy trees preserved. Bipolar SPME fibers were used to sample compounds in the headspace above samples of infected wood and uninfected wood. The compounds were then desorbed and separated through GC/MS. Results show that avocado trees infected with the laurel wilt produce different VOCs than trees that are uninfected by the pathogen. Based on these differences, a training aid will be created and subsequently verified through canine trials. This mimic training aid can then be used to combat the biothreat caused by *Raffaelea lauricola* and the skills and practices developed applied to the wider effort of protecting the nation's food supply from foreign invasive pests and other biothreats.

Biothreat, Canine Detection, *Raffaelea lauricola*

E12 Breaking Glass: Case Review of an In-Hospital Suicide

Bethany L. Bless, MS, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will have reviewed a case of suicide by sharp force injuries in a hospital inpatient setting.

This presentation will impact the forensic science community by contributing to the understanding of common reasons a person may commit suicide, although, in some cases, why the person committed suicide may never be known.

Suicide is the act of intentionally causing one's own death. It is often carried out as a result of despair, the cause of which may be associated with a psychiatric condition such as depression, bipolar disorder, schizophrenia, or borderline personality disorder. It may also be associated with substance abuse problems, such as alcoholism or drug abuse. Stress factors such as financial difficulties, declining health, or troubles with interpersonal relationships often play a role in why a person commits suicide. Occasionally the underlying reason for the suicide is unclear at the time of death and can remain unknown forever.

Harris County has a population of over four million people with approximately 4,000 deaths being reported to the medical examiner's office each year. Roughly 450 cases each year (approximately 11-12%) are classified as suicides. In Harris County in 2009, a total number of 4,153 cases were examined at the medical examiner's office. Of those cases, 484 (approximately 12%) were classified with a manner of death of suicide. Suicides by sharp force injury (cut and/or stab wounds) are rare and in 2009 accounted for only 3% of those deaths were classified as suicide.

This presentation will be a case review of suicide by sharp force injuries that occurred in a hospital inpatient setting. The decedent had a medical history of Hypertension (HTN) and was transported to the hospital after experiencing a syncopal episode. He reportedly had a history of alcohol abuse and had ceased drinking approximately nine days prior to the syncopal episode initiating the hospitalization. He denied any pain, shaking, nausea, or agitation. The decedent was admitted to the hospital with the diagnoses of syncope, severe hypertension, hyponatremia, hypokalemia, tachycardia, and rhabdomyolysis. He was admitted to a regular room on a medical floor and other than a slightly elevated temperature and heart rate, he had no documented complaints. Over time, and for unknown reasons, he became increasingly agitated. He reportedly attempted to asphyxiate himself using the cord of the nurse call button. Multiple nurses were required to remove the cord from around the decedent's neck. The decedent then proceeded to run and crash through the glass window of the hospital room in an attempt to jump out the window. Hospital personnel were able to keep him from jumping out the window; however, he grabbed a large shard of broken glass and utilized it to stab himself in the neck. Prior to this episode, the family reported no history of mental illness and no history of suicidal ideations or attempts. The decedent had voiced no complaints prior to the incident. Toxicology screens performed on hospital blood from the time of admission as well as autopsy samples were negative for common substances of abuse, including illicit drugs.

Although it is important to note any history of mental illness, suicidal ideations, or past attempts, the lack of such does not indicate the death could not be suicide. Scene investigation and witness accounts of the circumstances surrounding the death are crucial. Though adequate information can be obtained in order to classify the cause/manner of death, families may not ever have an answer to the question of why.

Suicide, Sharp-Force Injuries, Hospital

E13 Mortality Directly Related to Abuse Against the Elderly in Brazil: A Reality That Needs to Be Reported

Carmen Silvia M. Miziara, MD, PhD, Rua Capote Valente, 127/111, Sao Paulo 05409000, BRAZIL; Fabiana I. Carvalho, MD, Rua Capote Valente, 127/111, São Paulo, BRAZIL; Thiago Victa Teixeira, MD, Medical School of ABC, Rua Príncipe de Gales, 755, São Paulo, BRAZIL; and Ivan D. Miziara, MD, PhD, Rua Teodoro Sampaio, 352-22, Sao Paulo 05406000, BRAZIL*

After attending this presentation, attendees will better understand the reality of the causes of elderly deaths in Brazil. Attendees will learn how these deaths occur primarily due to physical violence; however, the majority of these assaults could be avoided if identified sooner.

This presentation will impact the forensic science community by communicating the aspects of mortality involved with the elderly due to recurrent physical assault in Brazil.

Purpose: Brazil is an “old country,” according to the World Health Organization (WHO), as more than 7% of the population is 60 or more years old (Census of the Brazilian Institute of Geography and Statistical, 2012).^{1,2} Along with this growth, the incidence and prevalence of deaths directly related to abuse against the elderly has also risen. The identification of violence against this vulnerable population is one way to prevent an increase of these fatal cases. The purpose of this study is to discover ways for professionals who care for the elderly to remain alert to this problem and, when discovered, to report the problem to the authorities.

Methods: This is a descriptive study based on data from the Information System for Notifiable Diseases (SINAN), a database of the Health Ministry of Brazil. The mortality rate of the elderly (more than 60 years of age) as a direct result of violence were analyzed for the period from 2009 to 2012 in relationship to the total number of deaths from violence in all ages during the same period.

Results: Men were the primary victims. The female mortality rate was high (above 10% in all years analyzed) and exceeded the male rate in the years 2009 and 2012 (10% and 13.8%, respectively). Regarding the recurrence of violence, men were the most frequent victims as compared to women; men were the most frequent victims of death as a direct result of violence, except in 2010 when female mortality exceeded that of males. In 2012, more than 15% of deaths due to recurrent violence in all age groups were elderly men. The instruments most used by offenders, in cases of physical violence, were blunt instruments, followed by knives and firearms, with the first resulting in the most fatalities. Among aggressors, sons were the major perpetrators, followed by friends and unknown people. Lower victim education was associated with higher frequency of deaths directly caused by violence. Neglect occurred predominantly in females, while economic violence was more common among men, although it has shown high rates in both genders.

Conclusions: The results shown in this study are alarming, even considering that the data most likely are underestimated. Many deaths are not associated with maltreatment. The omission of the aggressors concerning the precise reasons of deaths is a factor to be considered. As the elderly are susceptible victims of accidents, especially those accidents related to falls, many traumatic injuries caused by violence are not reported.

Elderly, Violence, Death

E14 Forensic Physical Evidence vs. Eyewitness Evidence: A Look at Their Contributions to Wrongful Convictions and Exonerations

Irene A. Estrada, MFS, National University, 11255 N Torrey Pines Road, La Jolla, CA 92037; Ismail M. Sebetan, MD, PhD*, National University, Forensic Sciences Program, 11255 N Torrey Pines Road, La Jolla, CA 92037-1011; and Paul Stein, PhD*, National University, Forensic Science Program, 11255 N Torrey Pines Road, La Jolla, CA 92037*

The goal of this presentation is to provide forensic scientists and legal personnel with information that would allow them to develop stricter policies and practices regarding the handling of eyewitness evidence and physical evidence in order to prevent wrongful convictions in the future.

This presentation will impact the forensic science community by allowing attendees to better understand the impact each type of evidence has in criminal investigations as well as the importance that reliability and accuracy of eyewitness testimony and forensic physical evidence have as independent contributors to wrongful convictions.

This presentation is based on the growing epidemic of wrongful convictions and exonerations taking place in the United States since 1989. Two main databases were referenced in this research: The National Registry of Exonerations and The Innocence Project. This study examined misinterpreted or falsified forensic physical evidence and three types of eyewitness evidence: mistaken witness identification, perjury, and false confessions. After the late 1980s, modern DNA typing methods allowed for successful testing of older and smaller biological sample quantities, helping to secure 316 exonerations. In this study, statistics were generated by calculating the frequencies at which each type of evidence occurred in the 1,362 wrongful convictions to date as well as the 316 DNA exonerations.

This study examined whether erroneous forensic physical evidence or erroneous eyewitness evidence was responsible for the majority of wrongful convictions; however, in many cases, multiple types of falsified or misleading evidence were involved simultaneously; therefore, results do not total 100% and do not allow for a direct comparison. The first hypothesis tested was that eyewitness evidence will be more impactful and credible to legal personnel and juries than would be forensic physical evidence. The second hypothesis was that eyewitness evidence will be less accurate and reliable than forensic physical evidence. The third hypothesis was that forensic evidence will be more likely to exonerate while eyewitness evidence would be more likely to wrongfully incriminate.

Results showed that eyewitness evidence was more than twice as prevalent as forensic physical evidence in wrongful convictions. Out of 1,362 exonerations, perjury was the leading cause of wrongful convictions (55.5%), mistaken eyewitness identification was the second (36.5%), misinterpreted or falsified forensic physical evidence was the third (22.1%), and false confessions were the fourth (12.2%); however, modern DNA testing was responsible for 316 exonerations (23.2%) since 1989. Of the 316 DNA exonerations, 134 cases (42.4%) involved falsified or misinterpreted evidence in the wrongful convictions, while nearly all cases (96.5%) involved erroneous eyewitness evidence.

These results show that the policies regarding handling of eyewitness evidence needs the most modification. If new policies and procedures are established for handling eyewitness and physical evidence, then the likelihood of erroneous evidence leading to wrongful convictions will be reduced. More research must be done to conclude exactly how many wrongful convictions and exonerations were a result of one particular form of evidence over the other.

DNA, Eyewitness, Physical Evidence

E15 Effective Use of the Multidisciplinary Approach Is Critical to Solving Contemporary Violent Crime

David J. Zeliff, MFS, 102 Glacier Way, Stafford, VA 22554; and Michael J. Bosse, MFS*, HQ, 19th MP Bn, CID, 314 Sasaoka Boulevard, WAAF, Schofield Barracks, HI 96857*

After attending this presentation, attendees will better appreciate the necessity of employing a multidisciplinary approach in violent crime investigation.

This presentation will impact the forensic science community by demonstrating that the complexity, motivations for, and high-level education-based execution of violent crimes necessitate effectively using a wide spectrum of disciplines within the forensic community.

The “Forensic Family” came together as part of task force and was responsible for solving several cold case murders and rapes.

The explosion of forensic crime dramas, true-life documentaries, and the parallel increase in available academic forensic education has forever impacted the art of criminal investigation. Savvy criminals are taught in a wide variety of areas how to circumvent traditional crime fighting strategies, thwart traditional crime scene processing techniques, and mask or obliterate various types of physical evidence traditionally associated with interpersonal violent crimes. The killer highlighted in this presentation owned multiple text books on trace evidence.

Over the course of more than 60 years of criminal investigative experience, a dramatic shift in the time and effort spent by perpetrators in staging or simply altering crime scenes, in an effort to avoid forensic detection, in even the most emotional and anger-fueled violent crimes has been seen. This study will present a case which illustrates how knowledge of forensic science affected the planning and execution of a murder, and how leveraging the multidisciplinary approach in processing the crime scene, incorporating the forensic pathology findings, and combining the results with traditional stalwart investigative methods resulted in identification of the perpetrator.

The illustrated case involved the murder of a single female soldier (mother of two children) in her government quarters where she was beaten, stabbed once, hit in the head with a hammer, manually strangled, and finally asphyxiated with a ligature. After seven months, a task force was formed and multiple members of the “Forensic Family” participated in the resolution of this investigation. The medical examiner’s office provided pathological assessment; the scene itself was assessed to include all blood patterns that allowed a sequencing of events; a panty hose wrapper was collected and analyzed which revealed a latent footwear impression that ultimately matched the footwear of the subject; skilled interviewing and cognitive interviewing techniques were used; and criminal analysis of method of operation resulted in the subject being identified in a triple murder, along with multiple break-ins, and rapes over a multi-year period along the east coast.

Ultimately, the subject was convicted and received a life sentence in prison. He was subsequently convicted of a triple murder and received the death sentence. The subject was executed in 2005 after all appeals were exhausted.

Multidisciplinary, Forensics, Violent Crimes

E16 Multidisciplinary Approach to a Staged Sexual Assault

*Steven Geniuk, MS**, 91-1043 Hookaahea Street, Ewa Beach, HI 96706; and *Arthur S. Chancellor, MA**, 131 Wed Denning Road, Angier, NC 27501

After attending this presentation, attendees will better appreciate the value of a multidisciplinary approach to investigations, including various principles of sex assault crime scene investigation, identification of key evidence, a diverse spectrum of laboratory examinations, and expert analysis of staging elements.

This presentation will impact the forensic science community by demonstrating how positive results were achieved through cooperation and teamwork among the entire forensic family involved in the case. No matter how far-flung the incidents, how remote the crime scenes, or how complex the scenario, investigators should coordinate efforts and approach the case from several angles for the highest chance of success.

This a case study demonstrates how an interdisciplinary approach to the investigation resolved a unique example of a complex staged sexual assault. Proper crime scene processing and collection of evidence allowed investigators, laboratory technicians, crime analysts, and subject matter experts to properly evaluate what happened, recognize how the subject of the investigation went about staging multiple scenes, and ultimately secure a confession and subsequent conviction of the perpetrator.

In this case, the victim, a soldier deployed to Afghanistan, reported she was assaulted by two men intent on raping her; however, she was able to fight them off. The victim was eventually returned from the combat zone to Georgia, where she then reported receiving two threatening notes, apparently from the suspects involved in the initial assault in Afghanistan. The victim was then transferred to Hawaii for her safety, but within two weeks of her arrival, she reported a blitz assault in her barracks room, where she was assaulted, tied up, and raped with a knife handle. In the last instance, the victim also claimed that the offender had written threatening comments on her body. Complicating the issue was the fact the victim positively identified a suspect during a lineup based on information from the initial incident. Investigation combined with several forensic examinations established all the reports were false. Once confronted with overwhelming forensic evidence, the victim confessed to falsifying each incident to facilitate a final transfer to a military base near her family.

This case study illustrates how a multidisciplinary approach provided investigators with the tools they needed to successfully resolve the case through proper application of sex assault crime scene investigation, analysis of the key pieces of evidence, appropriate use of a wide variety of laboratory disciplines, and incorporation of expert analysis.

Crime Scene, Sex Assault, Investigation

E17 Do We Have the Right Guy? Connecting One Suspect to Two Brutal Attempted Sexual Assaults in Neighboring Police Jurisdictions

Matthew C. Wietbrock, BS, 629 N 6th Street, Lafayette, IN 47909*

After attending this presentation, attendees will learn the details surrounding two brutal attempted rapes which occurred on a cold night in November 2005 on the campus of Purdue University. The offender of these attacks was quickly apprehended and the subsequent investigation led to a criminal conviction.

This presentation will impact the forensic science community by detailing forensic tasks which occurred as part of the criminal investigation as well as investigative strategies which were employed. The techniques which the suspect used to conceal his identity will be presented to educate the attendees as to these methods. The results of forensic laboratory examination, which helped lead to conviction, and lessons learned at trial will also be discussed.

The details of this case began just before 9:00 p.m. on November 29, 2005, when the Purdue University Police Department received an emergency 911 call which reported a possible sexual assault in the parking lot of a university sorority. A basic description of the suspect was obtained, and officers responded to the scene, looking for a “skinny-framed,” White male who had fled from the scene in an unknown direction.

Approximately 90 minutes later and 1.5 miles away, a second attack was reported, this time to the West Lafayette Police Department, as it occurred within their jurisdiction. Although the manner of the reported attack seemed similar, the description of the suspect was wildly different from the first attack. This description was that of a large, muscular Black male.

Shortly thereafter, a day-shift patrol sergeant, who had been working an overtime assignment, began patrolling the area between the attacks at his own initiative. He soon located an individual, matching the second suspect’s description, who appeared to be following a female who was walking down the sidewalk. Upon closer investigation, it was clear that the person had blood visible on his clothes and hands. He was then approached by officers and detained for further investigation. After a few initial denials, and a story about a bloody nose, he was taken into custody.

At the time of his detention, the suspect clearly resembled the description of the second attacker and immediate evidence as to his possible involvement in the first attack was yet to be provided by laboratory analysis.

The next night, another sexual assault was reported in the same area. This second night with a reported attack caused great alarm within and around the community. There was a question that had to be answered for investigators, more quickly than laboratory results could provide: Did they have the right suspect?

An unorthodox solution was thought of by a Purdue detective who made a call to a bloodhound handler with whom he had worked in the past. With the help of “Sam” the bloodhound and her trusty nose, investigators were able to connect, albeit circumstantially, the suspect of the first crime.

Later, the investigation proved that prior to the first attack, the suspect had fashioned a mask out of a tee-shirt to conceal his identity, and had even gone back to his residence to change clothes, prior to committing the second attempted rape.

This presentation will detail the forensic evidence which was collected and the eventual laboratory DNA results. Techniques utilized and lessons learned about the challenges of a complex investigation will also be discussed as well as the eventual sentence received by the suspect.

Attempted Rape, DNA, Bloodhound

E18 **Obscene Phone Calls: How to Consider This Hands-Off Offense**

Ingrid Bertsch, MA, University Hospital Center of Tours, Hopital Trousseau, Tours 37044 Cedex 9, FRANCE; and Sebastien Prat, MD, Forensic Psychiatry Department, St. Joseph's Centre for Mountain Health Services, 100 W 5th Street, Hamilton, ON L8N 3K7, CANADA*

After attending this presentation, attendees will be informed about obscene phone callers and their victims, their different profiles and associated behaviors, and the risk and impact of this type of hands-off offense.

This presentation will impact the forensic science community by highlighting an offense that is always considered as a non-dangerous behavior.

Introduction: For more than two decades, sexual offenses have been extensively studied. From those studies, many categories and profiles have been developed. This study makes a notable difference between hands-off and hands-on sexual offenses, and one particular type of offense came to light during this study — obscene phone calls. Most of these calls contain sexual words or are driven by sexual fantasies. One of the characteristics of this offense is that it impacts random victims, sometimes in the offender's professional area. In addition, this type of offense contains a wide range of behavior, from silent calls to the most pornographic and vulgar speeches.

Methods and Results: A literature review was conducted to analyze existing knowledge regarding the matter, particularly in terms of understanding this behavior. Unfortunately, this topic does not seem to have been something of interest as less than 20 scientific papers, over a period of more than 40 years, were collected.

Discussion: The apparent low level of interest of this offense seems to be in relation to the fact that obscene phone call are often disregarded and not considered as psychological violence; however, these offenders truly suffer from a mental condition. This presentation will describe the offenders' and victims' profiles and the psychopathological theories underlying this behavior. Prevention of re-offense by leading the callers to a therapeutic program seems to be hard to develop, since the victims often do not report the calls to the police. Raising public awareness of the reality of this behavior could help to protect both the victims and the offenders.

Obscene Phone Call, Hands-Off Offense, Phone Scatologia

E19 A Ten-Year Study of Suicides From a Rural/Suburban County

Robert J. Bready, MS, Dutchess County MEO, 168 Washington Street, Poughkeepsie, NY 12601; Jennifer C. Bready, PhD*, Mount Saint Mary College, 330 Powell Avenue, Newburgh, NY 12550; and Dennis J. Chute, MD, Dutchess County MEO, 168 Washington Street, Poughkeepsie, NY 12601*

The goal of this presentation is to share trends in suicide data compiled over ten years in Dutchess County, NY.

This presentation will impact the forensic science community by providing suicide data compiled in a rural/suburban setting for reference and comparison by medicolegal investigators and pathologists.

This data was based on reporting and examination standards recommended by the National Association of Medical Examiners and Department of Justice death investigation standards. Specifically, this study looks at suicide data from 2003 to 2013 collected from autopsies and external examinations reported to the Dutchess County Medical Examiner's Office. Almost 300 cases were analyzed using Statistical Package for the Social Sciences (SPSS) 20.0 in terms of the deceased's gender, age, race, presence of a suicide note, method of suicide, and weapon used. More than $\frac{3}{4}$ of the cases were male and less than $\frac{1}{4}$ were female, agreeing with the 2011 reporting of the Centers for Disease Control and Prevention (CDC) which states that 78% of all suicides are male.¹ The large majority of the deceased were White, with Blacks and Hispanics at less than 6% each. There was a wide variety of ages ranging from 15-94 years of age, with an average age of 49.29, and a standard deviation of 18.11. The largest age group was 46-55 years of age, with just over $\frac{1}{4}$ falling into this age bracket. This also matched other studies that indicate the highest rate of suicide is in the 45-54 years-of-age group.^{1,2} Only four cases were juveniles. There was no significant difference in the average age for men and for women.

Research shows quite a discrepancy in the percentage of suicides in which a note is found. Eckert and Helpert state about $\frac{1}{3}$ of victims left a note; in contrast, a study by Tewksbury, Suresh, and Holmes found 26.3% of males left a note, and a study by Shaw et al. that only looked at adolescents, found that 39% left a note.³⁻⁵ Furthermore, while there is much research about the content of notes, little more has been said about the presence of notes. In this sample, just over 40% of the cases left a suicide note, but there was no significant difference in the presence of a note for men or women, for different races, or for different age groups. Most common methods of death were gunshot wounds, hanging or asphyxia, and overdose, which is consistent with CDC data and other studies.^{1,4,6,7} The remaining methods include carbon monoxide or other poisoning, blunt force trauma, sharp force, drowning, or self immolation. Numerous studies cite that men are more likely to commit suicide by violent means, such as gunshots, whereas women are more likely to commit suicide by poison.^{2,7,8} Results from this study agree with other reports showing significant differences for method of death both in terms of age and gender, with men more likely to choose gunshot and women more likely to choose overdose. Furthermore, the older the deceased was, the more likely they were to commit suicide by gunshot, and the younger they were, the more likely they were to commit suicide by overdose. Of note, all four juveniles committed suicide by hanging. Statistical analysis could not be performed for race and method of suicide due to small numbers of other races, but there were interesting trends that will be discussed.

Lastly, the weapon used for method of death will be discussed as time permits. Specifically, the type of gun used, classified as handgun, shotgun, or rifle; materials used for hanging, which include ropes, cords, belts, sheets, and shoelaces; different gases used for poisoning; and weapons used in blunt force trauma cases.

Suicide, Suicide Note, Suicide Method

E20 Investigating Elder Deaths

*Julie A. Howe, MBA**, Saint Louis University, Franklin, Jefferson & St Charles MEO, College of Health Sciences, 3084, St. Louis, MO 63104-1028; *Kim A. Collins, MD**, LifePoint Organ and Tissue Donation Services, 3950 Faber Road, Charleston, SC 29405; and *Patricia King, RN**, Dept of Human Services Division of Aging Services, Forensic Special Investigation Unit, 2 Peachtree NW, Ste 33-284, Atlanta, GA 30303

After attending this presentation, attendees will better understand the signs and symptoms of elder maltreatment and the need to perform complete and thorough medicolegal death investigations in these cases, including scene investigations, ancillary studies such as toxicology screening, review of medical records, autopsy, and imaging when warranted in order to properly determine the cause and manner of death. Elder Death Review Teams (EDRT) provide interdisciplinary review of elder deaths in an attempt to develop prevention strategies to decrease the incidence of elder abuse.

This presentation will impact the forensic science community by emphasizing the need for comprehensive medicolegal death investigations in order to differentiate elder maltreatment from deaths due to natural disease of elders aged 60 years and older in suspicious deaths and to conduct interdisciplinary EDRT in an attempt to improve outcomes for this population.

The population of elders aged 60 years and over is projected to double in size and comprise 20% of the total United States population by 2050.¹ As this population grows, the maltreatment of elders is an increasing and disturbing problem worldwide. Research suggests that at least one in ten elders experiences some type of abuse but only one in 23 cases will be reported, according to the National Center on Elder Abuse.^{2,3}

Elders are a vulnerable population due to their pathophysiology and lack of overall healthcare understanding. Conditions other than natural disease processes, such as hip fractures, subdural hematomas, sepsis, untreated decubitus ulcers, and malnourishment, may hasten their death. The medicolegal community must ensure that thorough investigations are completed to separate normal and expected findings from abuse and neglect.

Only two states, Arkansas and Missouri, have laws that mandate reporting of elder deaths that occur in a residential care facility, assisted living facility, intermediate care facility, or skilled nursing facility to the medical examiner/coroner regardless of whether or not the death was due to natural causes.^{4,5} Furthermore, only 33 states or United States territories require the medical examiner/coroner or persons who perform the duties of the medical examiner/coroner to report cases of suspected abuse, leaving 31 states or territories without mandatory reporting requirements.⁶ In order to address epidemiological studies, consistent reporting is necessary.

It is paramount for individuals who investigate and document elder deaths to be properly trained in order to recognize possible signs of maltreatment. A systematic approach, beginning with the death and scene investigation, followed by a complete autopsy, concluding with an interdisciplinary elder death review ensures proper classification of cause and manner of death. This methodical approach also allows for the development of prevention measures to decrease the incidence of future cases.

Deaths of elders should not automatically be assumed to result from natural disease. Accidents, suicides, and homicides can and do occur in the elder population. The development of a comprehensive standardized reporting form to collect appropriate information will assist in differentiating these cases and will be discussed.

The Georgia Department of Human Services Division of Aging and the Fulton County Medical Examiner's Office collaborated to develop a database documenting demographic and risk factors for elder abuse, neglect, and exploitation cases.⁷ The team reviews cases weekly, notifying the medical examiner/coroner of any suspected maltreatment, initiating further investigation which may not have been pursued otherwise. The project will be discussed in detail.

Premature deaths of elders should be investigated as seriously as those of children and younger adults. This outlook will decrease the incidence of maltreatment occurring in a population that continues to grow as individuals live longer.

Elder Maltreatment, Geriatric, Scene Investigation

E21 **Bleeding Out: A Case of Mistaken Homicide**

Bethany L. Bless, MS, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand the importance of a complete and unbiased investigation when it comes to death investigations.

This presentation will impact the forensic science community by contributing to the understanding of the laws pertaining to assisted suicide and potential problems in determining the legal next-of-kin for disposition of remains.

Harris County has a population of more than four million people with approximately 4,000 deaths being reported to the medical examiner's office each year. In many cases, the cause of death is consistent with the witness statements and preliminary death scene investigation; however, sometimes the witness statements and preliminary law enforcement investigations are not consistent and a more in-depth death scene investigation is required by trained medicolegal death investigators. It is important for the medicolegal death investigator to approach all scene investigations without bias or predisposition as to cause of death.

With an evolving population, emerging technology, and the increase of crime scene-related television shows, death investigations are becoming more complicated. Not all crime scenes are what they appear to be. This presentation will review a case of mistaken homicide which was due to false/inconsistent witness statements. Law enforcement arrived on scene to find a large amount of blood throughout the decedent's residence. The decedent's 14-year-old grandson was reportedly in the residence with the decedent. Per the law enforcement report, the grandson reported that he stabbed the decedent two times. At first glance, the scene investigation was consistent with foul play due to the amount and location of blood and evidence including a bloody knife and a bleached footprint on the carpet. Trace evidence was collected on scene. During the medicolegal death investigation of the decedent's body, it was found that what had first appeared to be a homicide was now looking to be something very different. Photographs of the scene and autopsy will be used to show the evolution of the investigation, from the initially suspicious scene findings to the autopsy determination of the cause and manner of death.

This presentation will demonstrate the importance of a complete and accurate death scene investigation. The presentation will illustrate the importance of gathering accurate information and seeking further information when inconsistencies and questions arise during the initial scene investigation. Pathologists who perform the autopsies rely partly on a clear report from the medicolegal death investigator of the circumstances and observations of the death scene. Attendees will enhance their knowledge of death scene investigations and the need for clarity in death scene reports, despite inconsistencies that may arise.

Death Investigation, Homicide, Inconsistent Findings

E22 The “Spaghetti Bullet”: Difficulties Inherent in the Medicolegal Investigation of Deaths Caused by Non-Standard Ammunition

Lindsey A. Bayer, MS, 809 Pine Street, Leesburg, FL 34748; Brett E. Harding, MBA, District 5 MEO, 809 Pine Street, Leesburg, FL 34748; Wendy A. Lavezzi, MD, Office of the ME, District 5, 809 Pine Street, Leesburg, FL 34748; and Barbara C. Wolf, MD, District 5 MEO, 809 Pine Street, Leesburg, FL 34748*

After attending this presentation, attendees will understand the importance of forensic investigators and medical examiners being familiar with non-standard ammunition and firearms that they may encounter in medicolegal death investigations.

This presentation will impact the forensic science community by familiarizing forensic scientists and investigators with the importance of the multidisciplinary investigation in the medicolegal evaluation of deaths associated with firearms, particularly those involving atypical ammunition and/or weapons.

A wide variety of firearms ammunition is commercially available; however, many types of the ammunition are no longer being manufactured but can still be found in private collections and stockpiles. Knowledge of the composition and morphology of non-standard ammunition is essential for forensic investigators and pathologists, since these rounds are sometimes encountered in medicolegal death investigations. Similar to home-made ammunition, the interpretation of the morphology of the wounds caused by such rounds as well as the radiologic findings can be difficult for unfamiliar examiners. The following case illustrates these potential difficulties.

A 62-year-old man who was staying at the home of a friend’s parents telephoned his ex-wife, with whom he had a contentious relationship, and informed her that he planned to kill himself. She then heard what she thought were two gunshots and the phone line went dead. She called the local sheriff’s office and a deputy responded to the residence where the ex-spouse was staying. The residence was locked, but the deputy obtained a key from a neighbor and found the man deceased on the garage floor with a pistol in his hand and a pool of blood around his head. Three suicide notes were found in envelopes on the kitchen counter. The decedent was a former police chief in another jurisdiction and had been a police academy instructor.

Examination at the medical examiner’s office revealed an intra-oral gunshot wound involving the posterior hard palate. No exit wound was found. Radiographs of the head showed the presence of two unusual radio-opaque densities over the cranial vault, in addition to multiple skull fractures. The recovered projectile, which had produced an incomplete exit perforation in the posterior midline of the skull, consisted of a gray metal structure that resembled a tangled ball of spaghetti. The deformed, copper-colored jacket of a medium caliber bullet was also recovered. The postmortem examination was otherwise remarkable only for severe coronary arteriosclerosis and postmortem toxicological studies were negative. The cause of death was certified as “gunshot wound of head” and the manner of death was suicide. Because of the unusual nature of the projectile, consultation was sought from several firearms experts. It was eventually identified as a round introduced in the 1990s as non-toxic, lead-free ammunition for use by law enforcement. This round, which consisted of a woven, multi-stranded, jacketed, frangible zinc bullet, was subsequently found not to meet Federal Law Enforcement Training Centers (FLETC) standards and its production was discontinued.

This case demonstrates the difficulties that may ensue in the medicolegal evaluation of firearm deaths when atypical ammunition, including outdated and home-made rounds, as well as unusual firearms such as zip guns and nail guns, are used and highlights the importance of the multidisciplinary investigation.

Firearms Deaths, Atypical Ammunition, Medicolegal Investigation

E23 Blunt Force and Fire — Four Victims and the One Who Got Away: Case Study of a Serial Murderer

Dayle L. Hinman, BS, Farrell & Associates, Inc, 3830 S Highway A-1-A, Ste 4, #200, Melbourne Beach, FL 32951*

After attending this presentation, attendees will better appreciate the efficacy of collaborative working relationships between the various professional disciplines involved in criminal investigations.

This presentation will impact the forensic science community by exposing participants to some of the key steps that were utilized in solving a difficult serial murder investigation.

In the early morning hours of August 1, 1995, a man walking on the railroad tracks in the Allapattah produce district of Miami discovered the body of Vida Hicks. There was trauma to the victim's head and she was partially burned. It was not readily apparent if she was the victim of an accident or homicide. Nine weeks later, the body of Diane Nelms was discovered approximately 20 feet away at the same location. She had also sustained blunt trauma to the head and was burned postmortem. The similarities between the two cases were striking. The police presence in the area was immediately intensified and the business owners reacted by removing all foliage and debris to prevent cover for further attacks. This tactic effectively worked for the produce district but moved the offender a mile away. Cheryl Ray was attacked in a cemetery across from Biscayne Bay approximately three months later. Like the first two victims, she was bludgeoned, doused with an accelerant, and wooden matches were used to start her clothing on fire. A witness came forward who reported seeing Ms. Ray sitting on a bus bench outside the cemetery. She was talking with an African American male who had his hair styled in long dreadlocks. The witness assisted a police artist with a composite of the suspect. The intensity of the investigation increased significantly along with the area of patrol. Two months later, the offender struck again. Janice Cox was attacked inside an abandoned gas station west of the previously targeted areas in a very similar manner. The indoor scene provided a distinctive boot print that had not been available in the three previous outdoor scenes.

With the attacks occurring over an eight-month period of time, law enforcement strongly suspected that the offender was local to the area. The victims were all similar in age and appearance. The perpetrator most likely brought a weapon to the scene along with an accelerant and matches. Investigators suspected that the purpose of the fire was for some reason other than to destroy evidence and the offender apparently did not remain at the scenes to watch the fire. A task force comprised of law enforcement officers from the Miami Police, Florida Department of Law Enforcement, and the Federal Bureau of Investigation flooded the area in an effort to prevent further attacks, develop new leads, and hunt for the perpetrator. The investigation seemingly turned a corner when a woman they interviewed reported that she had previously fled from a man who attacked her and struck her on the head — before the murders began.

The investigation was successfully concluded due to the synergy created by the collaboration of the law enforcement and forensic community.

Serial Murder, Case Linkage, Interrogation

E24 Case Study: How the Murder of a 4-Year-Old Girl Changed the System

Carrie Costello, BA, 6329 Munsee Drive, West Lafayette, IN 47906*

After attending this presentation, attendees will have an understanding of how, after police found a four-year-old girl dead in her home from a head injury and blunt force trauma and learned that she had been tortured at the hands of her stepmother for at least six months prior to her death while her biological father did nothing to stop the abuse, multiple changes occurred within the Child Protective Services Department, Law Enforcement response, and resulted in new legislation.

This presentation will impact the forensic science community by not only examining the crime scene itself, but by also showing how an abusive stepmother intimidated police, child case workers, court-appointed advocates, family members, and neighbors into not recognizing and/or ignoring the horrific torture her 4-year-old stepdaughter endured. In addition, this presentation will show how the traditional gender roles in domestic violence cases can change, with the female (wife) being the abuser while the male (husband) takes on a more traditional victim role, resulting in his failure to protect his biological daughter. Finally, it will discuss how a sheriff's deputy lied about a well-being check on the victim, resulting in the deputy pleading guilty to charges of perjury.

On the morning of March 16, 2005, shortly after 6:00 a.m., a 911 call came into the Tippecanoe County Sheriff's Department reporting that a child had been choking and was possibly dead. Through the sheriff's and the coroner's investigation, it was learned that the night prior to the 911 call, the victim had her hands bound and her mouth duct taped shut. The torture this child endured included, but was not limited to, being beaten with a broken wooden cutting board, zip-tied to a highchair, forced to sleep on plywood in a make-shift room in the unheated garage, tied to a plastic playpen, and forced to eat a type of gruel her stepmother concocted, all in the name of discipline to correct unwanted behavior. The victim also had to endure cold baths, as she was secured to the faucet as punishment for wetting her pants and bed.

This presentation demonstrates how a happy, healthy, go-lucky child who thrived in a good environment turned into a child who rarely laughed and played, causing a learned-helplessness behavioral response.

There were multiple contacts with various agencies and missed opportunities for the system to protect this 4-year-old murder victim. From the age of two, the child was appointed a ward of the court, assigned a Court-Appointed Child Advocate and a Child Protective Services (CPS) case worker. The victim's biological mother was addicted to prescription drugs and had five child neglect cases against her. There are over 1,000 pages of court records related to the victim's status as a child in need of services. The victim's father had a previous conviction of battering a 13-year-old boy.

In the five years prior to her death, there were more than 40 calls/complaints to police about the stepmother's abusive behavior, including her alleged attempt to run over a neighborhood child with her vehicle. The maternal grandparents, who had temporary custody of the victim, obtained a lawyer and filed for visitation rights due to the victim's stepmother's refusal to allow the victim to interact with her extended family. This case dragged on and never received a hearing in court. Finally, court records show that one complaint filed with CPS was not investigated because, a case manager, noted "inappropriate discipline does not meet legal sufficiency for CPS to investigate."

The end result was how all of these different agencies came together to support the prosecution of the stepmother for murder and neglect and the father for neglect.

Homicide, Child Abuse/Torture, Domestic Violence

E25 Homicide Investigation and Cold Cases: Why Aren't We Clearing More Cases?

James M. Adcock, PhD, 175 Braeburn Road, East Longmeadow, MA 01028*

After attending this presentation, attendees will be informed concerning the improvement of the low resolution rate (clearances) of homicides and cold cases.

This presentation will impact the forensic science community by providing suggestions on how clearances of homicides can be improved.

Over the past decades, there has been a significant change in the numbers related to homicides in the United States with what appears to be little progress over the past 20 years. In 1993, nearly 25,000 murders were recorded by the Uniform Crime Reports (UCR) program with a clearance of about 67%. In 2012, 13,092 homicides were reported with a clearance of 62.5%. In 2010, ScrippsNews reported that from 1980 to 2008 the United States had accumulated nearly 185,000 unsolved murders. Based on the present known clearances of reported homicides through 2012, coupled with the thousands of unidentified bodies where manner-of-death is still undetermined, there are probably in excess of 200,000 unresolved murders.

It is known that physical evidence, especially DNA, is helpful in identifying perpetrators and exonerating the innocent. But the process is limited as DNA only resolves about 27%-30% of all the cases, therefore begging the question, what about the other 70%? Experience has shown not all homicides are solvable and some are more difficult than others even when the right protocols are followed. In the meantime, political leaders have allocated hundreds of thousands of dollars through the National Institute of Justice (NIJ) for items like the NIJ-sponsored DNA Cold Case Grants.

While many have benefitted from these funds, this grant limited recipients to only evidence that contained DNA potential with no consideration or even the potential use of other personal identifying evidence being found, such as latent prints. If it did not have DNA potential, then one was not allowed to use these funds for their cases. Furthermore, looking at the cold case research conducted for the NIJ, it was found that most of these grant-receiving agencies probably would not have even looked at their unresolved homicides or rapes had it not been for the availability of outside funds. Then, following the grant, many of the cold case units fell apart with few remaining, most likely due to the lack of adequate funding and support from management. So, the question is: how much is someone's life worth?

Sadly, as the literature regarding the clearances of homicides is reviewed, a plethora of articles are found, from sociological journals to criminal justice journals and others such as homicide studies. While these all have value, they do very little toward providing police supervisors or detectives with information that will help them increase their homicide clearances. Do not misunderstand — some authors from these journals have actually described specific measures that police can take that will help them resolve more cases; however, after valid research was published in 1999, there has not been any improvement in the percentage of clearances, even with a 47% drop in the number of reported homicides. It is highly likely that the same holds true of the publications by the other authors as well. Examples will be provided to illustrate the issues at hand and introduce possible solutions.

Homicides, Cold Cases, Clearances

E26 **Hyperspectral Remote Sensing: Detection of an Experimental Mass Grave Over Time and at Different Scales in a Temperate Environment**

Gabriela Ifimov, BA*, McGill University, Dept of Geography, 805 Sherbrooke, W, Montreal, PQ H3A 0B9, CANADA; George Leblanc, PhD, National Research Council of Canada, Flight Research Laboratory, Ottawa, ON K1A-0R6, CANADA; Margaret Kalacska, PhD, McGill University, Dept of Geography, 805 Sherbrooke, W, Montreal, QC H3A-0B9, CANADA; and Tim Moore, PhD, Dept Geography, 805 Sherbrooke Street, W, Montreal, Quebec H3A 2K6, CANADA

After attending this presentation, attendees will have a better understanding of hyperspectral remote sensing applications in clandestine mass grave detection at different spatial scales and of its limitations in a temperate ecosystem.

This presentation will impact the forensic science community by offering insights on the temporal changes in spectral reflectance of an experimental mass gravesite and will illustrate the utility of these results for the detection of deep clandestine gravesites to narrow down search areas.

Worldwide events such as war crimes and human rights abuses can result in the death of people who have historically been buried in mass graves. Common methods used for gravesite location, such as witness testimony, geophysical resistivity, magnetometry, or ground penetrating radar, can be time consuming and cover small geographical areas. Novel advances using remotely sensed data and techniques to detect changes in both soils and vegetation characteristics due to cadaver decomposition provide an alternative tool to detect buried remains.¹⁻³

The goal of this study is to determine, through the integration of field data, spectrometry, and airborne hyperspectral imagery, how an experimental mass gravesite's surface reflectance changes over time. The study consisted of the establishment of three experiment study sites, at a depth of approximately one meter, in June 2013: one experimental mass gravesite containing 20 pig carcasses (*Sus scrofa*) and disturbed soil; one reference containing only disturbed soil; and one undisturbed control site. To investigate the changes in the spectral reflectance of the experimental mass gravesite and its distinction from the non-gravesites, hyperspectral data was collected at different spatial scales over two growing seasons. Airborne hyperspectral imagery covering the Visible Near Infrared (VNIR) range (376nm to 1,048nm) and the near to shortwave infrared wavelength range (870nm to 2,500nm), was collected over the research area. A full-range spectroradiometer, (350nm to 2,500nm) was used to collect vegetation spectra in the field. In addition, leaf pigmentation (chlorophyll and carotenoids), and soil chemistry (e.g., C, N, Ca, Mg, Na) are used to inform the spectral analyses to differentiate between the gravesite and non-gravesite (disturbance and control).

Preliminary results show that burial depth and site age play an important role in the detectability of a mass gravesite in terms of changes in soil and vegetation. In the early stages of the study, differences in spectral signatures between the gravesite and the non-gravesite are a result of the overall disturbance effects rather than attributed to changes in soil and vegetation characteristics due to cadaver decomposition.

Hyperspectral Remote Sensing, Cadaver Detection, Mass Grave

E27 Debunking Three Myths About Rape Victims' Responses to Their Attacks

Mary Carr, MD*, Regions Hospital, 640 Jackson Street, MS 11102F, Saint Paul, MN 55101

After attending this presentation, attendees will learn that, contrary to endorsed beliefs, victims of rape do not necessarily immediately report the assault, suffer severe physical or anogenital injury, or forcefully resist their attacker during the assault.

This presentation will impact the forensic science community by providing supporting evidence, obtained from a retrospective study conducted at a Sexual Assault Nurse Examiner (SANE) program, that following a self-report of sexual assault, victims will seek medical care over a wide variation of time following the assault, rarely suffer moderate or severe physical or anogenital injury, and commonly do not resist their attacker throughout the assault.

Stereotypical and prejudicial misconceptions regarding sexual assault and victim responses to this type of violence continue to exist. These misconceptions are collectively referred to as rape myths. Three existing rape myths are that sexual assault victims: (1) immediately report the crime; (2) suffer severe physical and/or anogenital injuries; and, (3) forcefully resist their assailant. Failure by the lay public to understand the variability of victim response during and following a sexual assault can result in victims blaming themselves and lack of support provided to victims. In the courtroom, it can result in jurors misunderstanding that the victim did not consent and may result in not guilty verdicts for criminals. Having an expert witness provide testimony to the mythological nature of some long-held beliefs allows jurors to evaluate victim behaviors they otherwise find incomprehensible or counterintuitive.

A retrospective cohort study examining the time to seek medical care following the incident, presence of physical or anogenital injury, and level of physical resistance during the assault was conducted at Regions Hospital in St. Paul, MN, in 2011 and 2012. Study subjects were female sexual assault victims undergoing examination by a SANE.

SANE reports for 317 subjects met the inclusion criteria and were reviewed. Twelve (4%) victims experienced physical injury requiring medical intervention. A total of 34 (11%) sustained anogenital injuries requiring medical intervention. Overall, 253 (81%) victims did not actively resist at some point during the assault, with 178 (57%) victims never actively resisting. Nearly half (129; 43%) did not appear in the emergency department for 12 or more hours from the time of the assault.

It can be concluded from this study that female victims reporting a sexual assault seek emergency department assistance after the sexual assault in a variable amount of time, rarely suffer moderate or severe physical or anogenital injury, and commonly do not resist their attacker throughout the assault.

This study helps refute three rape myths which previously may have contributed to further victimizing the victim.

Rape Myth, Delayed Reporting, Injuries

E28 **Murder or Accidental Drowning in a Bathtub? Case Studies of Drowning and Non-Aquatic Homicides Staged as Bathtub Drowning Accidents and Suicides**

Andrea Zaferes, BA, PO Box 601, Shokan, NY 12481; and Mary E.S. Case, MD*, 6059 N Hanley Road, St. Louis, MO 63134*

After attending this presentation, attendees will be able to better recognize signs of foul play specific to several different types of pediatric and adult homicides committed either by drowning or by non-aquatic means that are then staged as bathtub drowning accidents or suicides.

This presentation will impact the forensic science community by providing an increased awareness of these types of Bodies-Found-In-Bathtub (BFIB) homicides with the goal of facilitating early recognition of red flags, more effective investigations, and successful, justified prosecutions.

Seven BFIB homicide cases will be reviewed. Initially, almost all of these cases were treated as drowning accidents until significant red flags of foul play were recognized, sometimes years later, causing the cases to be re-investigated with subsequent homicide conviction results. Each of these cases provides lessons learned that can be applied to all BFIB death investigations and prosecutions.

Homicides staged as drowning accidents in bathtubs present a number of challenges with the main challenge being a lack of specialty training. Law enforcement and medicolegal investigators investigating motor vehicle, fire, and airplane crash fatalities are usually assisted by crash reconstructionists, fire investigators, and Federal Aviation Administration/National Transportation Safety Board (FAA/NTSB) investigators, respectively, who typically have 40-1,000 hours of specialty training. When investigating aquatic fatalities, law enforcement and death investigators are rarely given similar assistance by aquatic death specialists and are at a further disadvantage by having little to no aquatic death and homicidal drowning investigation training.

The case studies presented represent several different types of BFIB homicides of which the forensic community needs to be made aware.

Two cases involved children. In one case, a 4-year-old male victim of premeditated homicide by his father was suffocated with Freon® with the scene staged as an accidental slip-and-fall bathtub drowning. The second case involved a 3-year-old male who was staged as a choking death on land after being drowned by his foster mother when dunking punishment went too far.

Five cases involved adult women murdered by their husbands or other family members. In the first case, a 45-year-old woman was assaulted and strangled in her bathroom, then deposited in her hot tub to stage an accidental drowning due to alcohol intoxication. This case remained diagnosed as a drowning accident until the offender confessed to family members years later.

A 46-year-old woman was drowned by her husband in a hot tub with subsequent accidental slip-and-fall staging. The first trial ended with a hung jury. A subsequent investigation was conducted, including a reconstruction that was necessary to support the statement of the neighbor who witnessed the assault but who didn't understand what she was observing. The second trial resulted in a homicide conviction.

Two cases involved elderly women murdered by suspected family members for monetary gain and staged to look like falls in bathtubs. One of the cases was an 87-year-old woman found in the bathtub filled with water in a secured condo with her face under the water. Autopsy revealed she had been strangled and beaten. The second case was a 74-year-old woman found in a bathtub with no water with extensive trauma to her posterior head and cervical spine and chest trauma. A soap dish on the wall was broken and fragments of that dish were found in her head wound. The trauma to the scalp was seven lacerations which certainly exceeded what would be expected in a simple fall. The cause of death was fracture of the C1 caused by the impacts to the head.

The remaining cases were of women drowned by their husbands with additional useful lessons learned regarding scene investigations and autopsy findings.

Drowning, Bathtub, Homicide

E29 Conservation Genetics of Bioko Monkeys

Cynthia R. Zmich, BS*, 40-44 196th Street, Flushing, NY 11358; Heather E. Mazzanti, MSFS, 450 S Easton Road, Glenside, PA 19038; Susan M. Gurney, PhD, Drexel University, Dept of Biology, 3245 Chestnut Street, PISB, Philadelphia, PA 19104; and Naomi Phillips, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038

After attending this presentation, attendees will understand how genotypic information from three endangered primate species can be used to further develop forensic wildlife molecular methods.

This presentation will impact the forensic science community by demonstrating how the use of genetic information can be used to assess the genetic health of three endangered primate species. More importantly, it will illustrate how this information can be used by forensic biologists to develop testing methods that can be used to deter crimes against wildlife.

Wildlife forensics deals with the legal and environmental aspects of crimes against animals. Newer research in this field is exploring the use of molecular approaches to forensic testing which can be used to deter crimes against wildlife. The focus of this research is three endangered primate species, *Procolobus pennantii pennantii* (red colobus), *Colobus satanas satanas* (black colobus), and *Mandrillus leucophaeus poensis* (African drill), from Biko Island. Biko Island is home to a multitude of unique species and is one of the world's top biodiversity hot spots. Many of the primate species on the island are endangered due to a thriving bushmeat market and habitat degradation. Despite legislative efforts and hunting bans making it illegal to kill these endangered species, the people on the island continue to do so with little to no consequence. While it is difficult to fine or prosecute individuals who hunt these creatures, the availability of genetic testing which can be implemented for forensic testing purposes, may deter hunters from preying on these protected species.

The goal of this research is to genotype the three endangered primate species mentioned above in an effort to determine genetic health of the populations for conservation efforts while evaluating loci for phylogeographic utility. No previous studies regarding the loss of heterozygosity of these primates have been published. Therefore, this research is desperately needed. Three classes of loci — traditional, bioinformatic and International Haplotype Map Project (HapMap) pairs — totaling 67 loci across the whole genome, have been identified as potentially valuable for genetic testing within these populations. This research focused on those loci located between chromosomes 1 and 2, of which there are 19 in total. Of the three species of interest, 49 individuals were genotyped using the three primer methods indicated above. Loci were scored as homozygous or heterozygous. Currently, four loci with heterozygosity ranging from 9% to 33% have been identified for use in determining the genetic health of these populations. Additionally, two of these loci are promising candidate markers for implementation in forensic conservation efforts.

Wildlife Forensics, Bioko Primates, Genome Sequencing

E30 Evaluating Methods for Removing Radioactive Contamination From Traditional Forensic Evidence: Moths

*Kelly Daniel**, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701; *Rachel Lindvall, BA*, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; *Lauren L. Richards-Waugh, PhD*, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; *Jason Chute, MSFS*, 1401 Forensic Science Drive, Huntington, WV 25701; and *Michael Kristo, PhD*, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550

After attending this presentation, attendees will understand some of the principles behind nuclear forensics and the need to decontaminate radioactively contaminated evidence.

This presentation will impact the forensic science community by demonstrating the potential of several solvents for removing radioactive contamination from traditional forensic evidence, specifically insects, without damaging the evidence.

Traditional forensic evidence, associated with interdicted nuclear material or an attack using a Radiological Dispersal Device (RDD or “dirty bomb”), may become contaminated by dispersible radioactive material. If so, such evidence must either be analyzed by a forensic laboratory capable of handling nuclear material or decontaminated prior to entering a traditional forensic science laboratory. There are few laboratories that are capable of handling dispersible radioactive material and, therefore, decontamination of the evidence with a method that does not destroy the evidentiary value would be preferred.

In 2009, Victoria, Australia, police found 300 grams of a uranium oxide compound in a storage property. After initial analysis by the Australian Science & Technology Organization (ANSTO), aliquots of the material were sent to Lawrence Livermore National Laboratory (LLNL) for further analysis. While aliquoting the sample for analysis, researchers at LLNL found the head and body of a moth. Analysis of the nuclear material indicated that it could not have originated within Australia. Entomological study of the moth could prove useful for understanding the history of the material from production to interdiction within Australia, a type of signature referred to as a “route attribution” signature in nuclear forensics; however, before the moth could be sent to an entomological laboratory, it would need to be decontaminated, a process that could well prove destructive.

To determine an effective and non-destructive method for decontamination of the evidence moth, exemplar moths were collected and contaminated with a uranium ore concentrate. Then, these contaminated moths were ultrasonicated in 11 solvent systems chosen for their potential decontamination properties. Mass difference was initially used to determine the efficacy of these solvents for decontamination, but Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) will be used in future work to determine residual uranium levels.

Four of the solvents (5% Radiacwash™, 5% Decon® 90, acetone, and 1% nitric acid) provided promising results. They removed a significant mass of the uranium ore concentrate without extensive damage to the moth; however, using mass difference to determine the amount of uranium ore concentrate removed from each moth by the solvation proved to be imprecise and sometimes difficult to interpret. For example, mass loss was sometimes greater than expected because of incomplete initial desiccation of the moths followed by a more complete desiccation after decontamination. In addition, the loss of wing scales during solvation seems to be unavoidable in all solvent systems. The moths decontaminated with the promising solvents were ashed and will be analyzed for remaining uranium content by ICP/MS. Future work may include DNA analysis of the moths to determine if DNA can be cleanly extracted from radioactively contaminated evidence.

Radioactive, Decontamination, Insects

E31 Discrimination of Human and Animal Blood Traces Via Raman Spectroscopy

Kyle C. Doty, BS*, 2165 Robinwood Avenue, Schenectady, NY 12306; Gregory McLaughlin, MS, 100 Manning Boulevard, Albany, NY 12203; and Igor K. Lednev, PhD*, 1400 Washington Avenue, Albany, NY 12222

After attending this presentation, attendees will become knowledgeable about how Raman spectroscopy coupled with chemometrics can be used to analyze, accurately identify, and discriminate between bloodstains from humans and 11 species of animals.

This presentation will impact the forensic science community by introducing a unique method for non-destructive bloodstain analysis and confirmatory identification, with a statistical level of confidence, which could potentially be performed at the crime scene.

The identification of a body fluid stain is an important and necessary aspect of many forensic investigations. Various presumptive tests are currently used for identifying a stain as blood; however, these tests are most commonly oxidation-reduction assays, which use hazardous chemicals and are destructive. Common confirmatory blood tests are microcrystal assays (e.g. Teichmann or Takayama assays). The Ouchterlony test, or similar immunochromatographic assays, can be employed to determine if the blood is non-human. It is ultimately preferable to confirm the presence of blood and the species of origin before forensic DNA profiling, but this can be practically problematic.

If a DNA profile is not extracted from the sample, then the suspected blood is usually presumed to be non-human and further characterization omitted. This is an erroneous testing scheme primarily because there is a lack of confidence that the sample is in fact blood, and of human origin, due to potential false positives. This approach could also be detrimental for crime labs since time and money would be wasted on non-human or non-blood samples. Since the amount of suspected blood evidence may be miniscule, it needs to be preserved and analyzed efficiently. Therefore, a non-destructive method to competently identify human blood would be highly valuable. Raman spectroscopy is a technique that has the potential as both a non-destructive confirmatory identification for blood and as a species of origin assay.

Raman spectroscopy has been proven as an effective and versatile analytical technique for a variety of forensic applications, including identification of lipsticks, drugs, explosives, paints, and fibers. Raman analysis often requires no sample preparation, is typically non-destructive, and has the ability to analyze microscopic amounts of sample. This technique is based on the detection of light that is inelastically scattered by a sample upon irradiation from a monochromatic light source. A Raman spectrum contains numerous distinctive bands which correspond to specific molecular vibrational modes. For blood in particular, Raman spectra provide rich detail and has been targeted in previous forensic studies. Popularity of Raman spectroscopy has been growing in forensic science especially due to reduced cost of instrumentation, including portable instruments, and its numerous possible applications.

This study has analyzed blood from twelve different species, including human. For forensic relevance, the animal (non-human) samples were selected to represent three groups: (1) animals that are bred for domestication (cat, dog, horse); (2) those consumed as food (chicken, cow, pig, rabbit); and, (3) those integrated with human existence (mouse, rat, opossum, raccoon). Analyzing a variety of animals' blood enhances the forensic practicality of the study and adds more certainty to model predictions. To account for the complexity of the dataset, Partial Least Squares Discriminant Analysis (PLSDA) classification models were utilized. The first PLSDA model differentiated between human and animal blood spectra in a binary fashion (human vs. animal).¹ The second PLSDA model was used to differentiate between human blood spectra and those from each species of animal surveyed.² To validate both models, classification predictions were made for a set of internal and external unknown samples. The constructed models exhibited a great ability to discriminate human from animal blood. This study demonstrated a comprehensive and robust method for analyzing a suspected bloodstain to identify human origin. The goal of the analytical approach is to be used for the rapid and non-destructive identification and characterization of a bloodstain at a crime scene.

This project was supported by Award No. 2011-DN-BX-K551 awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.

Raman Spectroscopy, Blood, Human

E32 The Optimization of Spermatozoa Extraction and the Study of the Retention of Spermatozoa on Machine-Washed Clothing

Nicole Gallo, BA*, 55 VA Braam Street, Pittsburgh, PA 15219

The goals of this presentation were to determine the variables/factors optimal for spermatozoa extraction and to determine if spermatozoa has the ability to retain on machine-washed clothing under various factors. The optimization of spermatozoa was performed while examining various factors including the time of extraction, the extraction solvent, and in-house vs. commercial stain. The retention of spermatozoa was examined under the variables of type of fabric, temperature of water, and detergent type.

This presentation will impact the forensic science community by discussing the preliminary results which suggest that not only is DNA able to retain on clothing through machine washing but also enough spermatozoa retains to obtain DNA profiles.

The presence of a suspect's seminal fluid on a victim's clothing often indicates the possibility of a sexual assault, particularly when the suspect and victim are not in close relation or association with each other. Many have speculated as to whether or not the detection of spermatozoa is either hindered and/or prohibited by machine washing; however, such areas are largely understudied. Previous work has failed to not only determine this possibility, but it also failed to address varying factors that may affect the retention of the spermatozoa.

The objective of this study was to determine if spermatozoa was, in fact, able to retain on clothing after machine washing under various factors such as the type of fabric and temperature of water (hot or cold). Furthermore, this study attempts to determine if the retained spermatozoa, if found, could produce a DNA profile adequate for analysis.

The seminal samples used in this study were collected from five donors and deposited via Pasteur pipets onto approximately 6"x6" swatches of five types of fabrics: cotton (underwear), denim, a sheet, a towel, and a cotton t-shirt. The transfer of spermatozoa onto the fabrics via pipet was performed as a laboratory control in order to eliminate uneven distribution as a factor of retention. Each of the five pre-stained fabrics were tested prior to machine washing for both Acid Phosphatase (AP) activity and fluorescence under the Alternative Light Source (ALS). All five fabrics tested positive for both AP and ALS. Additionally, an approximately 3x3mm cutting from each of the pre-stained samples underwent a two-hour, 1% Hydrochloric Acid (HCL) extraction, Christmas tree (Keruechtrot-Picroindigocarmine) staining, microscopy, and rating. The ratings ranged from 3+ to 4+ for all pre-stained samples. Each of the five pre-stained fabric samples were washed with a set size of pristine clothing for both the hot and cold wash. After washing, ten cuttings were taken from each fabric and viewed via microscopy. The cuttings were extracted under the same procedure as listed above, and examined via microscopy. Each of the fabrics were positive for spermatozoa in 100% of the cuttings taken. The sperm heads were counted for each fabric and ranged from 2-352 for the hot wash and 3-390 for the cold wash. During each of the washes, the washing machine, laundry detergent, cycle type, and size of load were kept constant to ensure no other factors were affecting the spermatozoa's retention. Also, a blank was run before each load to ensure no contamination from the machine itself. Finally, the cuttings were tested for DNA using a chelex extraction and Y-chromosomal Short Tandem Repeat (Y-STR) kit. The preliminary results suggest that not only is DNA able to retain on clothing through machine washing but also enough spermatozoa retains to obtain DNA profiles.

Retention, Spermatozoa, Washing

E33 Adding Value to Your Learning Event

Shirly Berends-Montero, PhD, Boomsluiterskade 39, Den Haag 2511VK, NETHERLANDS*

The goal of this presentation is to explain how to design an effective learning event through the implementation of the concepts of constructive alignment and Bloom's taxonomy.

This presentation will impact the forensic science community by creating awareness about the optimization of the process of teaching/training-learning forensic science. Although the content/example is given within the context of criminalistics at the professional level, the pedagogical and didactical concepts and methods are applicable to all levels and all fields.

Have you tried getting oranges from a fig tree? Would you use a trace elemental chemical profile to identify a substance as cocaine? Intuitively in daily work, activities are aligned with the expected products in mind. Forensic scientists constantly build and (re)validate knowledge and skills that could be applied to the respective fields in order to strengthen the justice system; however, when it comes to transferring that knowledge and skills, the goal is sometimes forgotten. It does not help the situation that the topics are incredibly interesting or that the interdisciplinary character of the profession is fascinating. As a matter of fact, the highly motivated learners and their perception of what they have actually learned may obscure the measuring of the learning results, which are used to calculate the Return On Investment (ROI). Effectively teaching forensic scientists has become a difficult task, especially when the relevancy and amount of knowledge is changing at a rapid rate. Instructors are expected to adapt their programs with a minimal time investment. In addition, they are expected to do so without sacrificing the content or the essential academic/professional skills that new practitioners need to have, such as scientific critical thinking and independent learning.

Traditional one-way (instructor-led) learning events as the only teaching modality has become ineffective with the new generations of learners, some accustomed to cutting corners and studying for the assessments. The instructor is expected to assume diverse roles such as organizer, planner, coach, and facilitator of the learning process. In other words, the role of the instructor as an effective instructional designer has become highly relevant. This is especially true when considering both the increasing scrutiny of the accreditation agencies responsible for the control of the quality of the educational curricula and the competences desired by the future employers.

Taking a closer look at how people learn and how this process can be optimized are necessary activities for all instructors, old or new. Although there are multiple teaching-learning theories available, the preferred ones agree that stimulating deep learning is an effective teaching practice. Constructive alignment is "a design for teaching calculated to encourage deep engagement."¹ As with other approaches to active learning, the essence of the constructive alignment theory is that the instructor/trainer doesn't have the central role in the knowledge transfer, but that the learner does. Integrating the Bloom's taxonomy of the cognitive domain in the design of a learning event becomes a necessity.² In other words, the cognitive skills desired as a consequence of the learning event have to be explicit. The alignment process starts by defining the desired results — they can be as high as strategic organizational results or a hypothetical assessment — and translating them to the operational learning outcomes according to Bloom's taxonomy for the cognitive domain. Next, the beginning situation is assessed and the learning activities are designed to "practice" the cognitive processes chosen for those learning outcomes.

This process will be exemplified with a curriculum for coordinators of forensic investigations within the Dutch police. This curriculum was the product of a team effort of the police academy, the Dutch police expertise center, the Netherlands Forensic Institute, and two universities. During this presentation, the process of designing, developing, implementing, and evaluating two modules of this curriculum, pertaining to criminalistics, will be discussed.

Constructive Alignment, Bloom's Taxonomy, Education and Training

E34 Comparing Resolution of Analog vs. Digital Imaging Systems in Postmortem Applications

Tania Grgurich, MS, Quinnipiac University, 275 Mount Carmel Avenue, NH-MED, Hamden, CT 06518; Gerald J. Conlogue, MHS, Quinnipiac University, Diagnostic Imaging Program, 275 Mount Carmel Avenue, Hamden, CT 06518; Natalie A. Pelletier, MHS, 275 Mount Carmel Avenue, Hamden, CT 06518; and Robert Lombardo, BS, Quinnipiac University, 275 Mount Carmel Avenue, Hamden, CT 06518*

After attending this presentation, attendees will have an understanding of the advantages and disadvantages of analog and digital imaging systems and the practicality of each for postmortem radiography, particularly when high-resolution images are necessary.

This presentation will impact the forensic community by identifying the imaging methods and modalities that maximize the resolution of radiographic images.

Radiography is often an integral part of the postmortem examination, and high quality radiographs are essential. Goals of postmortem radiography include screening for the presence or absence of bony trauma and foreign bodies such as bullets or knife blades, determining the presence of air emboli, identifying the decedent, and determining accidental vs. non-accidental trauma. In the past, film was the only available recording media for radiographic examinations and limitations of analog systems often made it difficult to acquire optimal images. Presently, several types of recording media are available for both medical and postmortem radiographic examinations. Analog systems, also known as film-screen radiography, consist of intensifying screens contained within a cassette and film as a recording media. A significant advantage of analog systems is their unmatched spatial resolution. Unfortunately, a number of disadvantages exist such as the inability to manipulate an analog image once it is taken and sub-optimal radiographs needing to be repeated. Analog radiography requires an automatic processor and darkroom to convert latent to manifest images and maintenance of the film processor and chemistry is essential for optimum image quality. Film cost and storage space are considerations, as are the inability to store, transmit, or view analog images electronically without first digitizing them.

In addition to analog, two types of digital imaging systems exist: Computed Radiography (CR) and Direct Digital Radiography (DR) systems. Digital recording systems, both CR and DR, provide high-quality images while overcoming many of the limitations of analog systems such as the inability to manipulate the image and the need for a darkroom, processor, and storage space. Unfortunately, many digital imaging systems are unable to achieve the resolution of their analog counterparts. This presentation compares the resolution of skeletal survey and specimen images of several infants radiographed using both analog and CR imaging systems. Each radiograph was evaluated for visibility of recorded detail by a board-certified radiologist and a pathologist. This presentation will weigh the advantages and disadvantages of analog and CR imaging systems, identify the imaging methods and modalities that optimize image resolution, and discuss the practicality of each type of imaging system for its use in postmortem radiography.

Forensic Radiography, Image Resolution, Digital Radiography

E35 Forensic Discrimination of Ballpoint Pen Inks on Documents Using LA-ICP/MS

*Jisook Min**, 331-1 Sinwol7-dong Yangcheon-gu, Seoul 158-097, SOUTH KOREA

After attending this presentation, attendees will learn the differentiation of ballpoint pen inks (black and blue) written on documents through an Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) methodology.

This presentation will impact the forensic science community by describing how to achieve discrimination on a forged document.

The differentiation of ballpoint pen inks (black and blue) written on documents through an LA-ICP/MS methodology is proposed. Size A4 white office paper containing ink strokes from ballpoint pens of known origin were cut and measured without any sample preparation. In a first step, Magnesium (Mg), Calcium (Ca), and Strontium (Sr) were proposed as Internal Standards (IS) and used in order to normalize elemental intensities and subtract background signals from the paper. Then, specific criteria were designed and employed to identify target elements which resulted independent of the IS chosen in most of the cases and allowed a qualitative clustering of the samples. In a second step, a normalization data based on the targets previously identified was used to obtain mass independent intensities and perform pairwise comparisons by means of statistical analyses. This treatment improved the Discrimination Power (DP) and provided objective results, achieving a complete differentiation among different brands and a partial differentiation within pen inks from the same brands. The results show that 25 samples of black ballpoint pens and 14 samples of blue ball point pens, all available on the local market, were successfully discriminated and identified.

Ballpoint Pen Inks, LA-ICP/MS, Forensic Discrimination

E36 Comparing 6,000 Consecutively Fired .40 Smith & Wesson® Bullets and Cartridge Cases From a Sig Sauer® P320 Pistol Utilizing 3D Imaging and Objective Comparative Analysis

Jennifer L. Stephenson, MSFS, Federal Bureau of Investigation, Laboratory Division, 2501 Investigation Parkway, Quantico, VA 22135; and Erich D. Smith, MS*, 2501 Investigation Parkway, Rm 4340, Quantico, VA 22135*

After attending this presentation, attendees will be aware of the acquisition techniques used by two types of 3D instruments, the correlation procedures used to interpret the data collected from test-fired bullets and cartridge cases, the application of the results as it relates to firearms identification, variations occurring throughout the sequence, and interpretation of the variations.

This presentation will impact the forensic science community by establishing/developing an objective means to evaluate an identification and serve as a confirmation to the firearms/tool marks theory of identification that the extent of sufficient agreement of individual characteristics occurring in tool marks produced by the same tool exceeds that agreement which occurs in tool marks produced by different tools. The presentation will also inform the forensic community of applications of emerging technologies within comparative-based disciplines.

This study was conducted to determine the variation of individual characteristics on test-fired bullets and cartridge cases over the lifetime of a Sig Sauer® P320 .40 Smith & Wesson® semiautomatic pistol. The pistol was purchased new and had only been fired by the manufacturer for a standard function test prior to this study. The ammunition selected for this study contained brass-jacketed bullets and nickel cartridge cases with nickel primers.

A total of 6,000 cartridges were consecutively fired for this study over a period of two weeks. Of the 6,000 cartridges, 342 were collected for analysis. Cartridge sets of 1-10, 91-100, 491-500, and 991-1,000 were collected and inter-compared for each 1,000-cartridge interval. In addition to the multiple test fire sets, every 50th cartridge was collected. Cartridges that were collected for analysis were fired into a ballistic water tank. Prior to test firing, a screw was inserted into the hollow-point cavity to prevent bullet expansion upon entry into the water tank. Cartridges that were not collected for analysis were fired in an indoor firearms range, then the bullets and cartridge cases were disposed of. No parts of the pistol were cleaned until after cartridge 6,000 was fired.

The first test fire was used as the reference sample for comparative analysis against all of the subsequent test fires. Prior to the 3D image acquisition, the bullets and cartridge cases were laser etched with a unique identifier and cleaned with acetone. The instruments were subjected to daily performance checks. Images of land impressions on the bullets were acquired using confocal microscopy and analyzed with the application of a cross-correlation function. Images of breech face marks on the cartridge cases were acquired using photometric stereo and analyzed with the application of a bidirectional reflectance distribution function. Both the cross-correlation and bidirectional reflectance distribution functions provided objective numerical values representing the similarity between two samples topography. The numerical values were used to determine if there was a significant variation of individual characteristics over the sequence of test fires and whether or not the variations would prevent a result of identification from being rendered. The bullets and cartridge cases were also examined by several firearms/tool marks examiners to determine if they were still identifiable by traditional means. Photographs of the pistol's barrel and breech face were taken prior to firing and at every 1,000-round interval. These photographs serve as an additional indication of variation of individual characteristics over the sequence of test fires due to wear. The photographs also indicated the extent of buildup of brass, lead, and other residues over the lifetime of the pistol without cleaning.

Reproducibility of Marks, Confocal Microscopy, Photometric Stereo

E37 Accidental Trauma Mimicking Homicidal Violence

*Samuel Prahlow**, Valparaiso University, 1212 Galien-Buchanan Road, Galien, MI 49113; *Alexander Arendt, BS*, Mishawaka PD & St. Joseph Co Metro Homicide Unit, 523 E Jefferson Boulevard, South Bend, IN 46617; *Thomas J. Cameron*, South Bend PD & St. Joseph Co Metro Homicide Unit, 523 E Jefferson Boulevard, South Bend, IN 46617; and *Joseph A. Prahlow, MD*, The Medical Foundation, 530 N Lafayette Boulevard, South Bend, IN 46601

After attending this presentation, participants will: (1) recognize that occasional deaths that initially appear to represent homicides actually represent accidental traumatic deaths; (2) understand the importance of careful scene and autopsy investigation in establishing whether or not a particular case represents a homicide or an accident; and, (3) appreciate the cooperation necessary between police agencies, death investigation agencies, and forensic pathologists in arriving at the correct conclusions regarding deaths due to trauma.

This presentation will impact the forensic science community by highlighting inter-agency cooperation in the investigation of cases in which initial police investigations are suspicious for homicide, yet, following careful scene and death investigation, it is determined that the cases actually represent accidental traumatic deaths.

One of the most important and publicly recognized responsibilities of death investigators involves the investigation of homicides. The identification and documentation of injuries, the appropriate collection and preservation of evidence, and the proper communication of findings can represent invaluable components to the overall crime investigation and eventual adjudication of a case. Despite the importance of excellent death investigation in the overall realm of homicide investigations, it is at least equally important, if not more important, for forensic pathologists and other investigators to work together to identify the occasional case where initial presentation is suspicious for homicide, but upon closer investigation, it is determined that death is due to accidental trauma. This study covers three cases, each of which had an initial investigation indicating a possible homicide. In each, only after a thorough scene and postmortem examination did it become evident that each decedent was the victim of an unfortunate accident.

Case 1: Police responded to a call in which an unknown male was found dead, lying in a bathtub that contained a pool of blood. An extensive hemorrhage appeared to be emanating from his axilla/chest. A blood-covered, broken ceramic pedestal sink stand was adjacent to the bathtub. Police considered the case a probable homicide. Autopsy revealed a deep sharp force injury of the axilla, with transection of the right axillary artery and right axillary vein. Toxicology testing revealed acute ethanol intoxication. Subsequent investigation revealed that the pedestal had been broken for many weeks. Based on these findings, it was determined that the drunken man apparently fell into the already-broken pedestal stand, causing the severe injury.

Case 2: Police responded to a call in which a 49-year-old male worker was found dead, lying face up at his workplace, a recycling center, with apparent head injuries. Two distinct lacerations were evident on the left side of his scalp and the initial police impression was that the case represented a probable homicide due to blunt head injuries. Autopsy revealed severe craniocerebral trauma, confirming the initial police suspicion of lethal head injuries. Subsequent investigation revealed that the man had been using a crane-operated heavy weight to break apart metal scrap for recycling. He had repeatedly been reprimanded for not staying in a designated protective work booth during this activity. He was found outside of the booth, with a piece of bloodstained shrapnel near his body. Based on these findings, it was determined that the man died as a result of an industrial accident.

Case 3: An elderly man living in a retirement home was found dead next to his bed, with his head resting against a blood-soaked mattress. His scalp had a large laceration, there was extensive blood spatter on the walls and elsewhere at the scene, and there were also items of overturned and broken furniture. The initial scene findings suggested a possible homicidal attack. A postmortem examination revealed a scalp laceration with underlying arterial injury. Subsequent investigation revealed that the intoxicated man had likely fallen onto a lamp, striking his head on a metal portion of the lamp, thus explaining the head wound. Toxicology testing revealed an elevated ethanol level, providing an explanation for the fall. His past medical history was significant for chronic alcoholism.

As exemplified by the three cases presented, correct cause and manner of death determinations are the result of cooperation between police, death investigation agencies, and forensic pathologists, as well as careful, detailed scene investigation, postmortem examination, and toxicology testing. Although each of the cases presented was initially considered an apparent homicide, detailed investigation allowed for appropriate death certification. The importance of careful observation, with correlation of scene, historical, toxicological, and postmortem examination findings cannot be overemphasized.

Homicide-Mimic, Accidental Death, Death Investigation

E38 Theoretical Evaluation of the Use of the Bloodstain Pooling Method as a Screening Technique

Khudooma S. Al Na'imi, MSc, Abu Dhabi Police General Directorate, Forensic Bio Sect, Forensic Evidence, PO Box 66722, Al Ain City - Abu Dhabi, UNITED ARAB EMIRATES; Zaina Alhattali, MSc*, Forensic Evidence Department, Abu Dhabi Police, Abu Dhabi, UNITED ARAB EMIRATES; Anwar M. Siddiqi, MSc, Abu Dhabi, PO Box 253, Abu Dhabi, UNITED ARAB EMIRATES; and Mahmoud B. Al Sharairi, BS, Abu Dhabi Police GHQ, PO Box 253, Abu Dhabi, UNITED ARAB EMIRATES*

After attending this presentation, attendees will understand the theory of the method which is used in sampling large numbers of bloodstains following blood-pattern analysis through pooling techniques as a screening method. The possible obstacles of this technique and its positive side will be discussed.

This presentation will impact the forensic science community by reviewing the method of using blood-pattern analysis in sampling bloodstains and the use of pooling techniques to check for the presence of stains from different contributors.

There is a continuous effort to make forensic testing more efficient and economical and to lower turn-around time and cost. This is especially important in cases that include large numbers of bloodstains being submitted for testing. Differentiating, sampling, and identification of different contributors of bloodstains are important for more accurate crime scene reconstruction and to identify the suspect or other persons related to the case.

Large numbers of bloodstains can be encountered in a multitude of crime scene-related areas such as clothes, different surfaces, tools, and the human body. The Scientific Working Group on Bloodstain Pattern Analysis (SWGSTAIN) identified multiple types of stain patterns which can be detected including altered drop, projected pattern, satellite stain, splash stain, swipe stain, transfer stain, swipe pattern, bubble ring, cast-off pattern, drip (stain, pattern, and trail), flow pattern, impact pattern, insect stain, and cessation cast-off patterns. Similar and different blood patterns from the same or different persons can be found either at the crime scene or on the collected evidence. Blood patterns can be used to differentiate between possible sources, but may be less helpful when the information about the case circumstances are limited or incorrect, making sampling based on Bloodstain Pattern Analysis (BPA) less effective.

Reliability of BPA was examined by a United States Department of Justice report which indicated that contextual information can affect the analysts' conclusions, which is a confirmatory bias.¹ This could show the need for a more quantitative method to be followed in the sampling decision.

The challenges reported by different experts in examining large numbers of bloodstains include the time-consuming nature of such sampling for DNA, when there is less reliability on BPA. To solve this issue, there is a need for a stain-screening method to check for the presence of a mixture or a single profile.

The pooling samples technique, suggested by Dorfman in 1943, is a known method in genetics and chemistry which examines members of a large population based on group testing theory.² It was Dorfman's proposed pooling for blood samples of groups of men inducted into the military service that tested the combined blood samples for antigens to identify the presence of syphilis.³ Currently, this method is used in biological testing, such as mutation detection.⁴ Forensically, based on this method, groups of bloodstain are pooled and tested for mixture profile.

When required, stains are classified into groups, either on the basis of the blood pattern(s) or of their location. Each group of samples is taken using either a wet swab or by excising a small piece of the material. Each group of samples is then pooled together for DNA analysis. In the case of the pool showing a single profile, there will be no future testing. The samples number in one pool will increase if there is a higher possibility of a single contributor, but the samples number will decrease in cases where there is a higher possibility of more than one contributor. If the pool of a group indicates a mixed profile, each stain in the group will be further assisted and resampled individually to locate the bloodstain which may have caused the mixture.

The advantages of this method include less testing required, the ability to screen large numbers of bloodstains, quicker results, less manual effort, reduced cost, and quicker location of different contributor's bloodstains. The use of the pooling method has several challenges including pool group size, equivalent quantity of DNA from each bloodstain, degradation of some mixed bloodstains (missing profile), and masked allele by major profile. The conditions which can affect using the pooling technique include the sample quantity, contamination issues, stain size, stain location, case requirements, number of contributors, unknown suspects, laboratory budget, laboratory quality procedures, case strategy, and results retention time. More research is needed to evaluate this method forensically.

Bloodstains, Blood Pattern Analysis, Pooling Technique

E39 A Bloodstain Pattern Analysis (BPA) Approach to the Shroud of Turin: A Step Forward

Luigi Garlaschelli, Via Ponte Vecchio 52, Pavia 27100, ITALY; and Matteo Borrini, PhD, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will understand how a Bloodstain Pattern Analysis (BPA) could be performed on the Shroud of Turin to reconstruct the original position of the man impressed on the linen.

This presentation will impact the forensic science community by demonstrating the new developments and potential of the BPA approach on uncommon pieces of evidence, suggesting further evaluation of one of the most controversial and valuable Christian relics.

Some of the presumed blood stains from the crucifixion wounds on the Shroud were approached forensically to reconstruct the body position during the blood flow, the crucifixion, and the ancient death penalty practice. A previous analysis presented the reconstruction of the position of the condemned with the hands above the head (arms/body angle near 80°).¹

Part of this new study focuses on the possibility of being nailed to a simple pole and not to the horizontal branch of a cross (patibulum), as proposed by biblical interpretation. The end of a transfusion cannula, connected to a drip chamber, was fixed at the wrist at Destot's space to simulate the bleeding from a puncture-type injury where it is usually believed that the nail for the crucifixion was positioned. Real human blood and synthetic blood for BPA were used with comparable results.

A ballistic angle finder was used, measuring the forearm-body angles when the hands are directly above the head (110° and 130°). In these cases, the blood trickled down on the radial part of the forearm, opposite to what is observed on the Shroud.

To verify whether the rivulets could be generated by a postmortem bleeding, the subject was laying with his hands crossed on the pubis, therefore the blood flow was in the same pattern as in the Shroud. Tests with different angle of the support surface (-5°, 0°, +5°) have been performed.

In none of these positions did the rivulets run as on the Shroud, but flowed parallel to the forearm for a few centimeters, then dripped toward the lateral or medial side of the forearm. The rivulets also never ran at an angle comparable to the two shorter stains located on the back of the left hand of the Shroud.

To investigate the shape of the nail wound on the hand and the two short rivulets, a preliminary test was set up to simulate the bleeding on contact with a wood surface, like the patibulum. Synthetic blood (0.3mL) was applied onto the back of the hand of a living volunteer; pieces of wood with different textures (from bark to smooth finish) were pressed on the hand for ten seconds and the resulting pattern observed. The results were not conclusive, since the wound is not clearly decipherable and in some cases the texture of the wood left its own imprint. This result underlines how difficult it is to speculate on the actual location of the nail's exit wound based on the imprint on the Turin Shroud.

In addition, this study set up a first BPA for the spear wound on the chest. On a mannequin's torso, a sponge with the same dimension of the wound was soaked in synthetic blood and then pressed at the corresponding area. In a standing position, according to the theory of the bleeding on the cross, vertical rivulets flow only on the front of the torso, with a shape congruent with the Shroud image.

Other theories suggest that the "blood belt" on the back of the image was the result of a postmortem bleeding of the subject after the removal from the cross. On a horizontal torso (support surface angle -5°, 0°, +5°), the rivulets flow sideways and posteriorly to the scapular region, where they form a large pool absorbed by the fabric and create a corresponding imprint on the body. All of this evidence is completely non-consistent with the features on the Shroud. Further studies should be performed on this topic.

New in-depth analyses on the presumed bloodstains on the Shroud of Turin will be presented, corroborating the previous results regarding the arm positions and illustrating some inconsistencies regarding the other red stains. Further BPA evaluation is highly recommended to better understand this controversial relic and the crucifixion as a death penalty.

E40 The Flipped Classroom — Turning Your Forensic Education Program Upside-Down

Thomas P. Mauriello, MFS, 8775 Teresa Lane, Laurel, MD 20723*

After attending this presentation, attendees will be acquainted with the new blended-learning pedagogy movement, which is the art and science of teaching and learning, and learn how this pertains to the forensic sciences education community. Blended learning is a formal education program in which a student learns, at least in part, through online delivery of content and instruction. The Flipped Classroom format, a form of blended learning, demonstrates how students learn new content online by watching video lectures at home or in the office, and what used to be homework is now done in the classroom.

This presentation will impact the forensic science community by providing attendees with the knowledge and technical skills used to present academic content in a manner that best meets the needs and expectations of today's students. The Flipped Classroom blended-learning format provides flexible time and delivery for both the student and teacher; manages content quality control; engages students in the learning process; and satisfies the new teaching and learning pedagogy movement being experienced in our universities today.

The term "Flipped Classroom" has become something of a buzzword in the last several years, driven in part by high-profile publications in *The New York Times*, *The Chronicle of Higher Education*, and *Science*.¹ In essence, "flipping the classroom" means that students gain first exposure to new material outside of the classroom. This is usually accomplished via readings, lecture videos or YouTube® clips, and extensive online activities; students then use class time (live events) to do the harder work of assimilating that knowledge through laboratory experiences, problem-solving, discussion, case studies, and debates.

The advantages of the Flipped Classroom format is that it: (1) meets the needs and expectations of students today; (2) allows for maximum flexibility of time and delivery for both the instructor and students; (3) allows for the management of content quality control; (4) engages students in the learning process; and, (5) satisfies the new teaching and learning pedagogy movement that is sweeping the globe. For example, scheduled video lectures are not hampered by inclement weather, outside commitments, holidays, etc., so you are always on track. Video lectures are viewed on demand by the student 24/7 and therefore, reduce the in-class time requirements.

This presentation will highlight the positive outcomes achieved by "flipping" the forensic classroom and strategies used to rebuild forensic coursework derived from 36 years of teaching forensic sciences. In addition, the dynamics of rebuilding forensic coursework and a demonstration of the power of today's technologies to "make a difference" by "making it different" will be described.

E41 Asylum Seekers Alleging Torture in Their Countries: Evaluation of a French Center

Renaud Clément, MD, 1 Rue Gaston Veil, Nantes 44093, FRANCE*

After attending this presentation, attendees will better understand methods and circumstances of assault which are crucial for performing efficient forensic examination of asylum seekers.

This presentation will impact the forensic science community by presenting the clear clinical characteristics, the methods of torture used, and the evidence of corroborating wounds that permit us to build a body of knowledge of torture's physical aspects for forensic medical examiners.

This study will characterize the physical evidence of torture experienced by asylum seekers requesting treatment at an academic hospital in western France.

Materials and Methods: Over a six-year period, all refugees examined by forensic physicians were evaluated with the goal of cataloging the physical evidence of torture. Sociological data, declared violence (single physical altercation, repeated physical violence less than one year or more than one year, incarceration not more than one week, or incarceration more than one week), and method of violence (blows by blunt object, crushing, burns, electrical shocks, attempted drowning, smothering, incision, or gunshot) were studied. An association between victims' statements and physical evidence of torture was determined.

Results: Of the 570 survivors assessed, 70% were male with an average age between 31 and 93 years. Dagestan was the country most represented among asylum seekers, followed by Guinea-Bissau and Guinea-Conakry. These countries were dominated by political conflict. Beatings were reported by 27.89%, confinement was reported by 40.22%, and repeated violence was reported by 30.16% of refugees. The average time interval between the first assault and evaluation was 53 months. Forms of torture reported included blunt force trauma (82.51%) including truncheon blows (27.50%), arm incision (30%), and burns (16.3%). Statistically, truncheon blows were experienced more often by males in confinement due to political conflict. The use of crushing methods and electrical shocks also were experienced more often by males during confinement. Victims who had received incision wounds were significantly younger. Gunshots were statistically associated with male survivors of political conflict. Men experienced drowning and electrical shocks while in confinement in the Balkans, Asia, and Russia. Electrical shocks were reported by males during confinement and in northern Caucasus countries. The association between assertions of burns and the presence of cutaneous scars was significant ($p=0.0105$); similarly, assertions of incision wounds were significantly corroborated by evidence of scars ($p=0.0009$). Of note, the association between victims' claims of gunshot and the presence of physical evidence was not significant.

Discussion: Asylum seekers who requested forensic medical examinations were usually young men. The geographic distribution and proportion of asylum seeker countries of origin were different between this single site in France when compared to French national statistics and those of the European Union. Beatings with blunt objects were the most often-reported form of torture used during episodes of repeated violence and during confinement. Assertions of burns were not associated with any particular circumstances. Electrical shocks were reported during confinement and most often in countries of the northern Caucasus. Attempted drowning, smothering, and shocking were noted, but these methods typically do not leave physical evidence or have health sequelae. Wounds resulting from burns and incisions usually leave scars that corroborate refugee statements. Torture by crushing and gunshot were reported by asylum seekers for the first time.

Conclusion: Investigation of the types of torture and circumstances under which torture occurs is critical for efficient forensic evaluation of claims of torture experienced by asylum seekers.

Asylum Seekers, Physical Assessment, Torture/Scars

E42 Forensic Podiatry — Pedal Evidence in Forensic Casework

Kewal Krishan, PhD, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160 014, INDIA; Tanuj Kanchan, MD, Dept of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575 001, INDIA; and John A. DiMaggio, DPM, 1450 Polaris Lane, SW, Bandon, OR 97411-8816*

After attending this presentation, attendees will understand the value of an important and emerging sub-discipline of forensic science, i.e., forensic podiatry, which deals with the examination of pedal evidence usually encountered at crime scenes.

This presentation will impact the forensic science community by presenting the utility of a comparatively new sub-section of forensic science which is concerned with the inspection of pedal evidence at crime scenes; this may motivate young forensic scientists to take up this discipline for research and practice.

Forensic podiatry is a comparatively new scientific sub-discipline of forensic science which deals with the examination of pedal evidence generally encountered at crime scenes. According to DiMaggio and Vernon, it is defined as the application of sound and researched podiatric knowledge and experience in forensic investigations, to show the association of an individual with a scene of crime, or to answer any other legal question concerned with the foot or footwear that requires knowledge of the functioning foot.¹ Forensic podiatrists contribute to the personal identification in forensic investigations whenever foot-related evidence is recovered from a crime scene. The need to establish the identity of dismembered remains may arise in cases of mass fatality incidents such as terrorist attacks, mass murders, transport accidents, tsunamis, floods, and earthquakes. Dismembered and mutilated remains are usually encountered in these mass fatality incidents. There is an increased likelihood of the recovery of feet (often enclosed in shoes), separated from the body in mass disasters such as high-power explosions and bomb blasts, airplane crashes, and other high-impact transportation accidents. In this regard, forensic podiatrists can collect the evidence related to the foot and assist in the identification of the individual from the foot and its parts. Furthermore, forensic podiatrists conduct the examination of footprints generally recovered at the crime scene. Footprints are commonly recovered at every crime scene in the form of bare footprints, socked footprints, or shoe prints.

There are many ways in which footprints can be used in establishing personal identification in forensic podiatry. The analysis of bare footprints involves identification based upon the individualistic characteristics of the footprints. Features such as corns, pits, ridges, humps, creases, deformity, an extra toe, riding toes, missing toe in the foot impression, and flat footedness are considered as individualistic characteristics of the footprints which can be utilized as forensic evidence in establishing personal identification. This kind of physical evidence can positively link a suspect to a crime or it can prove one's innocence. By using different anthropometric methods, the stature, sex, and body weight can also be estimated from the footprints recovered at the crime scene. As stature and body weight can provide an idea about the size of the individual, they can also provide useful clues to a forensic scientist in criminal investigation. Apart from these evidences in forensic podiatry, gait analysis and step/stride length analysis can also furnish some indication about the criminals involved in a particular case.

This presentation will discuss various methods of personal identification related to the pedal evidence which is usually recovered from the crime scene or scene of occurrence in the form of mutilated/dismembered remains, footprints, or questioned footwear.

Forensic Podiatry, Pedal Evidence, Foot and Footprint Characters

E43 Analyzing Law Enforcement Officer Reaction Time in Shooting Events Using 3D Computer Animation

Parris Ward, JD, Biodynamics Engineering, Inc, 17383 W Sunset Boulevard, Ste 290, Pacific Palisades, CA 90272; and William J. Lewinski, PhD, Force Science Institute, 124 E Walnut Street, Ste 120, Mankato, MN 56001*

After attending this presentation, attendees will understand how 3D computer animation can be used to demonstrate officer reaction time in lethal force situations.

This presentation will impact the forensic science community by demonstrating techniques for illustrating, and thus better understanding, how reaction time affects law enforcement officers' performances in shooting events.

Bullet paths in shooting events are routinely analyzed by 3D computer modeling. Computer-Aided Design (CAD) and 3D-animation software are excellent tools for the analysis of such events because of the software's ability to demonstrate spatial relationships between objects and people. When a model of a scene is created, bullet paths can be depicted as lines through space, from their point of origin to the objects they strike. When reviewing dynamic shooting events, animation software can be used to analyze the event in terms of motion and timing, which can be helpful in explaining why an officer's recollection of the event is not consistent with the forensic evidence.

A typical example of such an event is when a suspect in a motor vehicle attempts to run over a police officer. The officer, in fear for his or her life, remembers shooting at the driver through the windshield of the vehicle as it approached; however, examination of the physical evidence shows that the bullet entered through the side of the vehicle and not the windshield. How can this discrepancy be explained? If one were to diagram just that instant in time when the bullet left the gun, one might draw the conclusion that the officer was no longer in mortal danger since the vehicle had already passed by. And, that being the case, was the use of such lethal force still justified?

Law enforcement officers often have to make split-second decisions on when to use lethal force. A failure to take appropriate action could cost them their lives or the lives of others. When confronted with a threat, the officer must mentally perceive, process, and react to that threat, which requires a certain amount of time. Thus, there is a reaction-time delay between when the threat occurs and when the officer pulls the trigger on a gun. The same is true when a threat has abated. Once an officer starts shooting, it takes a certain amount of time for an officer to realize that he or she is no longer in danger and to stop firing.

This presentation will look at three shooting incidents where officers fired at moving vehicles and provided statements that were in some ways inconsistent with the physical evidence. In each case, the speed and path of the vehicle, as well as the location of the officer relative to the vehicle, could be accurately defined, and thus could be modeled and animated with a high degree of precision. Once the animated model was created, it was then possible to go back and look at what the officer saw at various points in time, prior to actually pulling the trigger. Correlating that information with data from reaction-time studies helped to explain why the officers fired when they did.

Computer Animation, Shootings, Reaction Time

E44 Death During Restraint: Excited Delirium vs. Positional Asphyxia

Werner U. Spitz, MD*, *Forensic Pathology/Toxicology, 23001 Greater Mack Avenue, Saint Clair Shores, MI 48080*

After attending this presentation, attendees will understand the mechanism of death during restraint.

This presentation will impact the forensic science community by discussing how to evaluate, certify, and testify in cases of deaths during restraint.

Rarely in the history of medicine has there been so much controversy regarding the mechanism of sudden collapse and death during restraint. Then, many years of speculation came to a sudden halt when Dr. Theodore Chan, an Emergency Room (ER) physician in San Diego who headed a number of studies on this topic, laid to rest previously held opinions that compression during restraint is unrelated to asphyxia, but due instead to Excited Delirium (ED).

On March 5, 2010, in Federal Court in Laramie, WY, Dr. Chan testified that his experiments with volunteers in the prone position, with up to 225 lbs. on their backs, were not meant to replicate conditions in the street. Indeed, Judge Johnson in his ruling states that Dr. Chan, in his testimony and in his published research, explicitly acknowledges that the two situations are not comparable (i.e., testing in the laboratory and restraint in the street).

Considering these recent developments, it is clear that ED is simply a long-known reaction to catecholamines. If ED were a cause of death, why then does it occur exclusively during restraint in prone position with compression causing immobilization of the chest and abdomen, when the abdominal organs are pushed against the diaphragm? Ronald O'Halloran, MD, past medical examiner of Ventura County, CA, asked why is it that the police are always present when someone dies of ED.

Consider the case of an autistic teenager who was in a state of acute psychosis. His parents called 911 to transport their son to the hospital. Police accompanied an ambulance to the scene.

A scuffle developed with several of the officers, during which the boy was placed in prone position and forcibly held to the ground. He suddenly calmed down and stopped fighting and screaming. His mother thought he was dead. When fire rescue personnel arrived, he was still face down, handcuffed, hobbled, unresponsive, and in cardiorespiratory arrest. Cardiopulmonary Resuscitation (CPR) was performed en route to the hospital. On arrival at the ER, he was diagnosed with anoxic encephalopathy and put on life support. Three weeks later, life support was withdrawn and death was pronounced.

The medical examiner handling the case had the event re-enacted using the two original officers to perform the restraint on one of their own officers in the same way as they had previously restrained the boy.

Within <1 minute, the officer being restrained indicated he could not breathe. The restraining officers did not believe him and continued the restraint. The restrained officer became panicked and violent because he was experiencing air hunger. When the officers finally realized he was in trouble, they released him.

Dr. Vincent DiMaio testified in this case. He opined that the cause of death was ED syndrome. Further, he stated that 225 lbs. doesn't impair the ability to breathe and it would probably take approximately 800-900 lbs. to arrive at that point.

One can only look forward to a time when compression of an individual in an acute psychotic state is replaced by treatment in a medical facility.

Positional Asphyxia, Excited Delirium, Restraint

E45 **Spatters Matter: How Bloodstain Evidence Influenced the Police at the Scene and the Prosecutor and Jury in the Courtroom**

Daniel V. Christman, MS, Snohomish County Medical Examiner's Office, PO Box 823, Bothell, WA 98041*

The goals of this presentation are to analyze the relationship of science and the law and apply the principles of forensic science with crime scene investigation techniques. This presentation will also discuss scientific methods and examine the evidentiary value of bloodstain patterns within a homicide scene, on the victim, and on the suspect and will illustrate that an investigator's opinions must be grounded in the analysis of the physical evidence and all known facts in the case.

This presentation will impact the forensic science community by helping attendees understand some basic principles associated with bloodstain pattern analysis, crime scene investigation, and scientific correlations of fluid dynamics to the resulting evidence within the featured homicide case. Attendees will also be challenged to give equal emphasis to all feasible and reasonable possibilities when considering answers to unknowns by implementing scientific methods to problem-solve the crime scene and develop a hypothesis.

This study uses a homicide case which includes bloodstain pattern analysis, blunt force trauma, and the correlation of injuries as well as a series of misdirected efforts to implicate and prosecute a husband in his wife's murder. On May 18, 1992, Gerald L. O'Grady relaxed in his West Vancouver, Canada, apartment and watched television while his wife worked in the kitchen. He wanted his wife to join him so Mr. O'Grady left the television room and walked toward the kitchen. There he found the room painted with blood and his wife's lifeless body on the floor — a victim of a brutal attack. The 70-year-old O'Grady started Cardiopulmonary Resuscitation (CPR) but, when fatigue set in, he stopped and called 911 for help.

Police and Emergency Medical Services (EMS) responded to the apartment where they found the front door dead-bolted. O'Grady opened the door from the inside and, standing before them, the first responders saw an elderly man with bloodstains covering his face, arms, clothing, and shoes. While EMS tended to his mortally wounded wife, the police became increasingly suspicious of Mr. O'Grady, questioning him at length about his alleged discovery of his injured wife as well as the exceptional bloodstains covering him. Mrs. O'Grady was taken to the hospital and Mr. O'Grady was taken to the police station for further questioning. Mrs. O'Grady died a short time later and Gerald O'Grady was ultimately charged with murdering his wife and was booked into jail.

Mr. O'Grady's defense counsel alleged that someone else entered the apartment that fateful night and savagely attacked Mrs. O'Grady in the kitchen while Mr. O'Grady watched television in another room in their residence. The prosecution countered that Mr. O'Grady murdered his wife. They believed the bloodstain evidence found at the crime scene, and most especially on Mr. O'Grady, would serve to convict him of his wife's murder.

During the first trial in 1993, the primary crime scene investigator gave conflicting, but honest, testimony. The jury found Mr. O'Grady guilty of second-degree murder. That conviction was successfully appealed in 1995, and a new trial was ordered on the grounds that "fresh evidence regarding blood spatter could have affected the result." New evidence was presented in the second trial, which ended in a mistrial in 1996 because the jury was unable to reach a unanimous verdict. The Crown Counsel (prosecution) then tried Mr. O'Grady for a third time. In the final trial, Gerald O'Grady was ultimately convicted of the second-degree murder of his wife and sentenced to life in prison; however, the physical evidence collected at the crime scene tells its own compelling story and, presented objectively, it supports Mr. O'Grady's account of the actions he took on that fateful night. In the end and in spite of the verdict, the physical evidence proves beyond a reasonable doubt that Mr. O'Grady did not commit his wife's murder.

This presentation examines the role physical evidence played in the trial process and how it was, or wasn't, used in Mr. O'Grady's original trial, in the second direct appeal trial, and in his third and last trial wherein Mr. O'Grady was finally convicted of murder. Mr. O'Grady died of natural causes while serving his sentence at the Ferndale Institution in Mission, British Columbia, Canada in 2004. He was 81 years of age.

Bloodstain, Evidence, Fluid-Dynamics

E46 Are We There Yet? The Testing of Unsubmitted Sexual Assault Kits and the Development of New Research Partnerships

Heather E. Waltke, MS, 3601 Connecticut Avenue, NW, Unit 120, Washington, DC 20008; and Gerald M. LaPorte, MSFS, National Institute of Justice, Office of Inv & Forensic Science, 810 Seventh Street, NW, Washington, DC 20531*

After attending this presentation, attendees will be more knowledgeable about federal support to state and local law enforcement agencies in their efforts to reduce the number of unsubmitted Sexual Assault Kits (SAKs).

This presentation will impact the forensic science community by demonstrating what research reveals regarding the nature of unsubmitted SAKs.

The National Institute of Justice (NIJ), the research, development, and evaluation agency of the United States Department of Justice, leads the nation in supporting the forensic sciences through research and by providing state and local crime labs with funding to help process and test evidence more efficiently in an effort to reduce backlogs. NIJ continually draws on the needs of practitioners to inform its research and programmatic agenda. This presentation will focus on a research initiative that is designed to help provide information concerning evidence collection, processing practices, and testing protocols for SAKs. Specifically, this research initiative is an endeavor to help address a major need in our nation's forensic science and criminal justice communities: to support state and local law enforcement agencies in their efforts to reduce the number of unsubmitted SAKs.

The focus of this effort is in the collection and analysis of valuable data concerning the nature of sexual assault evidence contained in previously unsubmitted SAKs. Further, obtaining an understanding of the various processes associated with analysis such as screening and testing are fundamental in the effort to inform best practices for collecting, analyzing, and testing evidence from sexual assault cases specific to the processing of large quantities of unsubmitted SAKs. The knowledge garnered as a result of this effort will be used to fulfill the long-term goal of improving current and future best practices for collecting quality evidence and processing SAKs in a more timely and efficient manner.

Over the years, forensic DNA analysis has proven to be invaluable to the law enforcement community, the victims of violent crimes, and their families. This initiative also directly supports the goal of carrying out analysis of samples from untested, unsubmitted SAKs so DNA profiles can be developed and placed in the National DNA Index System (NDIS). More violent crimes are solved as more DNA profiles are placed in NDIS, which is considered one part of the Combined DNA Index System (CODIS), the Federal Bureau of Investigation's (FBI) program of support for criminal justice DNA databases, as well as the software used to run these databases. NDIS has been particularly helpful to investigations that are very old and no longer producing new leads.

Decades ago, crimes from cold cases would have remained unsolved. The national database has been instrumental in solving violent crimes and providing valuable investigative leads to law enforcement. The upload of eligible profiles generated from DNA analysis as a result of this research initiative into NDIS provides direct aid in the investigation of violent crimes involving sexual assault and in the capability to solve more crimes to ultimately hold more criminals accountable. After attending this presentation, attendees will learn about NIJ's efforts to support state and local law enforcement agencies in their efforts to reduce the number of unsubmitted SAKs. In addition, attendees will learn about what research reveals regarding the nature of unsubmitted SAKs.

Sexual Assault Kits, Rape Kits, Untested Rape Kits

E47 Estimation of Human Age Using N-Glycan Profiles From Bloodstains

Dragan Primorac, MD, PhD, 471 Wolcott Lane, Orange, CT 06477*

After attending this presentation, attendees will learn the importance of glycans in human age estimation and that a bloodstain could be used to predict the age of an offender who committed a crime even few years ago, which represents valuable progress in the field of forensic science.

This presentation will impact the forensic science community by providing findings demonstrating that the analysis of the N-glycan profile could be a useful tool in forensics for determining human age estimation from dried bloodstains found at the crime scene.

Protein glycosylation is the most common epiproteomic modification that is involved in numerous physiological and pathological processes. Previous studies reported strong associations between human plasma N-glycans and age, prompting this study to evaluate the potential application of this biological phenomenon in the field of forensics.

Blood from 526 blood donors from different parts of Croatia was collected on bloodstain cards during the period of 2004-2007 and stored at +4°C for 6-9 years. Glycosylation profiles of the bloodstains were analyzed using Hydrophilic Interaction Liquid Chromatography/Ultra Performance Liquid Chromatography (HILIC/UPLC). The statistically significant correlation between N-glycan profiles of bloodstains and chronological age was found and the statistical model that can be used for the age prediction was designed ($Age = 75.59 - 5.15 \times (GP4)^2 + 17.07 \times GP6 - 5.30 \times (GP10)^2 - 16.56 \times GP16 + 20.07 \times GP20 - 7.54(GP20)^2 + 16.47 \times GP22$).

$$Age = 75.59 - 5.15 \times (GP4)^2 + 17.07 \times GP6 - 5.30 \times (GP10)^2 - 16.56 \times GP16 + 20.07 \times GP20 - 7.54(GP20)^2 + 16.47 \times GP22$$

This model explains 47.78% of variation in age, with the prediction error of 9.07 years. This study's findings demonstrate that the analysis of the N-glycan profile could be a useful tool in forensics, providing human age estimation from dried bloodstains found at the crime scene.

Glycans, Age, Bloodstain

E48 Ambient Ionization Mass Spectrometric Detection of Homemade Explosives in the Presence of Precursors

*Edward Sisco, MS**, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 20899; and *Thomas P. Forbes, PhD*, National Institute of Standards and Technology, 100 Bureau Drive, Gaithersburg, MD 21075

After attending this presentation, attendees will have a better understanding of how the concurrent mass spectrometric detection of homemade explosives and their precursors can be affected by factors such as competitive ionization and differences in chemical properties.

This presentation will impact the forensic science community by providing methods for the detection of homemade explosives in the presence of their precursor chemicals and other complex matrices. The presentation will also present methods to mitigate deleterious effects caused by the presence of precursor molecules.

Chemical analysis and detection of explosives is a well-explored area of forensic science in which numerous methods have been investigated. Techniques such as Gas Chromatography/Mass Spectrometry (GC/MS), infrared spectroscopy, and colorimetric tests can all readily detect a wide range of explosives in both pure form and in complex matrices; however, the capabilities of one of the emerging techniques in forensic science, Ambient Ionization/Mass Spectrometry (AI/MS), has been significantly less researched due to the recent advent of the platform. Most work completed thus far, regarding AI/MS capabilities, has focused on the detection of pure compounds or common military-grade explosives in known matrices. While it is essential to evaluate the performance characteristics of these techniques under controlled conditions, it is equally as important to investigate common homemade and improvised explosives. Two common classes of homemade explosives are sugar alcohol-based nitrate ester explosives, such as Erythritol Tetranitrate (ETN) and Xylitol Pentanitrate (XPN), and peroxide-based explosives, such as Triacetone Triperoxide (TATP) and Hexamethylene Triperoxide Diamine (HMTD). Since these compounds are typically homemade, it is crucial to understand their performance characteristics and potential detection issues both in pure form and in mixtures with their precursors.

This work focuses on identifying potential advantages and issues in the detection of homemade explosives when found in the presence of their common precursor chemicals using AI/MS platforms. The main platform investigated is Direct Analysis in Real Time Mass Spectrometry (DART[®]-MS). DART[®]-MS has been shown to rapidly and sensitively detect a number of explosive compounds from various classes with minimal-to-no-sample preparation. Utilizing a heated stream of helium metastable atoms, ionization of explosives rapidly occurs through either adduct formation, deprotonation, or protonation. One of the major benefits and drawbacks of the DART[®]-MS and AI techniques in general is the lack of a chromatographic separation prior to ionization and mass spectral detection. While this lends itself to rapid sampling times, it also may prove deleterious when complex mixtures are analyzed. Competitive ionization and differences in chemical properties can favor ionization and detection of one compound over another.

A number of sugar alcohol-based explosives were analyzed by DART[®]-MS as neat compounds and in the presence of their common precursors, sugar alcohols and nitric acid. Through analysis of these mixtures, it was found that competitive ionization does occur when these compounds are concurrently sampled. Relative affinity for free nitrate ions and differences in vapor pressures of the explosives and related sugar alcohols components can lead to diminished detection limits of the explosive component. Furthermore, extracted ion chromatographs of the mixtures highlight how different ionization pathways are preferred in the presence of different combinations of precursors, with adduct formation with free nitrates being the dominant pathway for both components. Studies have also been completed which focused on maintaining the sensitivity of the explosive compound by altering the chemical properties of the atmosphere near the sampling area, through dopant introduction. This work has shown that different ionization pathways can be emphasized depending upon the dopant species present. While current work has focused on sugar alcohol-based explosives, work is now continuing and will be presented on understanding peroxide-based explosives and their precursors as well as investigating additional AI/MS-based techniques such as Desorption Electro-Flow Focusing Ionization/Mass Spectrometry (DEFFI/MS).

Homemade Explosives, DART[®]-MS, Competitive Ionization

E49 Casework Analysis When Reference Data Aren't Available for the Observed Insect Species

Neal H. Haskell, PhD*, 425 Kannal Avenue, Rensselaer, IN 47978

After attending this presentation, attendees will better understand how to use closely related blow fly species growth data to determine Postmortem Interval (PMI) for cases where species growth and development data is not available.

This presentation will impact the forensic science community by enabling estimation of the PMI when growth and developmental data are not available for the blow fly species which are found on decomposing remains. This is accomplished by using known developmental data on closely related species which are available.

The use of insect evidence to determine the Postmortem Interval (PMI) and to answer other questions surrounding a death scene has been in common use in hundreds of case investigations for more than two decades around the globe. In most cases, blow flies (*Diptera: Calliphoridae*) are used singly or in combination as the Primary Indicator Species for the known time of their growth and development which can then be used to calculate an estimated range of time (minimum to maximum) of when the death of the individual occurred. In this calculation, there is usually an additional estimated time for various delays which may occur prior to initial colonization (egg laying). Thus, after the blow fly species is identified, the developmental table for that specific species is then consulted. By factoring in the known environmental temperatures coupled with the growth and developmental data, the estimated range of when death most likely occurred is determined.

However, there are times when a species of blow fly is recovered from remains and the developmental data has not been determined for that species. This is usually due to the enormous effort required in resources, time, and funding to generate reliable growth data for a species. In addition, the species may be limited to a geographic area, but very commonly, the area has not been well surveyed as to what species are present, and thus the species has not been studied to any extent. The forensic entomologist is faced with the dilemma of which data set to select for that unknown (growth-wise) species. Usually, these understudied species will have a closely related, sister species which has been studied extensively. Therefore, it is possible to apply the known rearing data of extensively studied species to the species for which there is little or no data available.

This forensic entomologist has used the data set for blow fly and flesh fly species of Adel Kamal, which have been available for more than 50 years. With a few exceptions for tropical species data sets which have been found to be reliable, these growth and development tables of Kamal have proven reliable, accurate, and verified by information of the known time-of-death for a particular case. With this established, the Kamal data can then be used as the base data for sister species estimations for which there is no established growth and development data.

The most commonly used species in North America is *Phormia regina*, a warmer weather blow fly, and in the same tribe as the screw worm species. Through case work and research, it was seen that *Cochliomyia macellaria* was very near the development range of *P. regina*. Thus, before data were available for *C. macellaria*, data for *P. regina* was applied to *C. macellaria*. Once publication of the developmental data was compiled for *C. macellaria*, it was seen that *C. macellaria* was approximately 12 to 24 hours quicker for the completed total life cycle than *P. regina*. When larval stages were present and the time of development for those larvae was half the total time or less, the difference was negligible. This rationale also followed for the *Lucilia* species complex consisting of the most common green bottle flies, those being *Lucilia sericata*, *Lucilia illustris*, and *Lucilia coeruleiviridis*. There was ample data for *L. sericata*, but nothing for the other two species which were commonly encountered in hundreds of cases across North America. Therefore, the data for *L. sericata* was used as the data for these other two species. Again, once data had been accumulated for growth and development of *L. illustris* and *L. coeruleiviridis*, it was found that these two species were slightly slower than *L. sericata* by 24 to 48 hours for the total life cycle duration. As in the case with *P. regina* and *C. macellaria* where only a portion of the total life cycle was involved, the differences were greatly diminished. Since *L. sericata* is the fastest of the three species studied, when *L. sericata* was used it would establish the absolute minimum time for the time-since-death for that case. Also, the inclusion of variability into the estimated range far exceeded the small difference in the specific calculation.

Forensic Entomology, Blow Fly, PMI

E50 The Impact of 3D Digitizations and Printed Models of Osteological Trauma When Presented to the Jury as Demonstrative Evidence

David A. Errickson, MSc, 18 Woodlea, Middlesbrough, England, UNITED KINGDOM; Tim Thompson, PhD, Teesside University, School of Science & Engineering, Borough Road, Middlesbrough, Cleveland TS1 3BA, UNITED KINGDOM; and Brian W.J. Rankin, MSc, Teesside University, Borough Road, Middlesbrough TS1 3BA, UNITED KINGDOM*

After attending this presentation, attendees will gain better understanding of the importance and the need for 3D digitizations within the courtroom. Furthermore, attendees will recognize the positive impact these digitizations have on jurors.

This presentation will impact the forensic science community by demonstrating the potential of 3D digitizations within forensic anthropology and the courtroom. Additionally, the forensic science community will see the advantages of these techniques as an explanatory tool for the jury.

Virtual environments, simulations, and 3D images are becoming commonplace within some jurisdictions, specifically in the United States; however, there has been a slower adoption of these techniques in the United Kingdom. As osteological trauma cannot be taken into the courtroom due to its sensitive nature, photography and, more recently, 3D digitization through the use of computed tomography, magnetic resonance imaging, and surface scanning has been utilized for visual representation of demonstrative evidence. Although there are a number of advantages discussed within the literature, including its visual and illustrative prowess, some of the negativities have yet to be debated or investigated.

One of the biggest limitations for using this technology within the courtroom is whether these techniques have any influence over the decision-making process or will bias the evidence visualized within the courtroom. Also, it is important to understand whether these displays deflect the viewer's attention away from the key issues and whether the jury is willing to accept the scenario into which they are placed. As a result, experiments must be designed to determine the effects of newer visualization methods so that any influence that could be created can be avoided.

The present study used a transcript to mimic an actual court case. As a control, each of the juries listened to the same case under the same conditions within an actual courtroom; however, for the demonstrational evidence presented by the expert witness, different displays for the same exhibit (osteological trauma to a cranium) were shown. This included verbal description, photographic images, 3D digitizations, and 3D printed models. Following the case, each member of the jury had to answer a questionnaire relating to the case and the particular technique they saw. The questionnaire was designed to determine each individual opinion on the outcome of the case and the demonstrative techniques that were used.

This research showed that the jurors for each of the demonstrative techniques gave the same verdicts in their case. This meant that when using 3D techniques, no influence was created over the jurors. The results showed that the jurors felt that the 3D digitizations and 3D models were more appropriate for demonstrating complicated information and helped clarify technical jargon over standard demonstrative techniques. Furthermore, these techniques do not bias the outcome of the results, demonstrated spatially what was being discussed by the expert witness, and therefore could be implemented within the courtroom to relay technical information to non-technically minded people.

Surface Scanning, Demonstrative Evidence, Jurors

E51 Multidimensional Model for Assessing Student Achievement

Catherine G. Rushton, MSFS, Marshall University Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701; and Ronald B. Childress, EdD, Marshall University, College of Education and Professional Development, 100 Angus E Peyton Drive, South Charleston, WV 25303*

After attending this presentation, attendees will be able to adapt a proposed multidimensional model for evaluating student achievement in forensic science higher education.

This presentation will impact the forensic science community by defining what successful student achievement encompasses. The assessment of student achievement demonstrates accountability and academic quality of a forensic science academic program to the forensic science community and public.

Complex tasks engage students in active learning; however, it is difficult to measure student progress with an objective exam. Students demonstrate their knowledge not as discreet items but rather across a continuum. Assessment strategies should incorporate situated judgments and contextual information to adequately evaluate the decisions made by students while performing complex tasks.

Currently, the primary tool utilized to assess student achievement in higher education forensic science programs is the Forensic Science Aptitude Test (FSAT) or an in-house comprehensive exam. A single standardized test does not accurately assess a student's ability to perform efficiently or effectively in a laboratory. This presentation will present the preliminary findings from a study directed at creating a multidimensional framework by which institutions can assess student achievement in forensic science education. Such a framework would provide a structure for forensic science programs to document student performance and demonstrate program quality and accountability to crime laboratories and the public.

Specific questions addressed in this study include: (1) How do forensic science education programs evaluate student achievement?; (2) How do disciplines other than forensic science evaluate student achievement?; (3) What knowledge, skills, and abilities are forensic science laboratory personnel expected to possess in an accredited laboratory?; (4) What standards/policies/best practices would best define successful student achievement in a forensic science undergraduate program?; and, (5) What standards/policies/best practices would best define successful student achievement in a forensic science graduate program?

The proposed framework was derived from literature assessing student achievement in higher education as well as from accreditation standards for forensic science and other academic disciplines such as nursing, medicine, and education. Accreditation standards for higher education institutions such as Council for Higher Education Accreditation (CHEA) and Middle States Commission on Higher Education (MSHEA) were also reviewed. Additionally, current standards utilized to assess student achievement by forensic science academic programs were reviewed to identify promising models. The practices identified in the various accreditation standards and promising practices were aligned with the International Organization for Standardization and the International Electrotechnical Commission (ISO/IEC) 17025 general requirements for the competence of testing and calibration laboratory standards.

Institution and discipline-specific accreditation standards incorporate several strategies for demonstrating student achievement including: (1) completion of degree coursework; (2) capstone experience or independent research projects, both with a written report; (3) completion of a comprehensive examination (in-house, FSAT, certification, licensure, or boards); and, (4) post-graduation employment or graduate school.

Literature on assessing student learning stresses that evaluation of student learning should occur at all levels and stages of the forensic science education process. Summative assessments, like the FSAT and comprehensive exams, provide one measure of a student's knowledge; however, formative assessments tend to have a greater impact on student knowledge and skills because of the reduced risk. Formative assessments, such as reflection and self-evaluation, allow students to explore both strengths and weaknesses. Most university faculty members have been given little formal training in how to develop formative assessments or measurable outcomes that can be assessed by multiple strategies.

Higher Education Policy, Evaluation, Student Achievement

E52 Creating a Positive Connection for Your Forensic Science Discipline

Sandra R. Enslow, BA, 4700 Ramona Boulevard, Rm LL40, Monterey Park, CA 91754; and Catyana R. Skory Falsetti, MFS, 1312 E Coolidge Street, Phoenix, AZ 85014*

After attending this presentation, attendees will better understand a solution for connecting disparate forensic practitioners within a specific field such as forensic art.

This presentation will impact the forensic science community by describing the process whereby social media has been used as a platform for professional communication.

Using the LinkedIn[®] social networking service, the Forensic Artists Discussion Group was established in 2009. It has more than 300 members globally connecting approximately 275 working forensic art professionals as well as representing affiliated disciplines including anthropology, odontology, pathology, and anatomy. Nurturing the development of this group and encouraging cross-discipline discussion is the primary purpose. Finding common ground in a forensic field where most practitioners are widely distributed and singular in their organization is an issue that has long needed to be addressed. Creating a platform for input, discussion, and exchange of ideas is the first step in developing cohesion. This development included identifying and personally contacting unattached practitioners and inviting them to the group. This is an example of a discipline taking the onus upon itself to create an outlet to advance professionalism, develop goals for advancement, and generate consensus.

The Forensic Artists Discussion Group focuses on professional concerns of the field including updates on new techniques, sponsored training, national events that affect the discipline, and employment opportunities. The group is a moderated, unbiased venue for information and materials. Discussion is monitored and guidelines have been established for professional conduct from participants. It serves as a communication conduit for all professional groups including the International Association for Identification (IAI), American Academy of Forensic Sciences (AAFS), British Association for Human Identification (BAHID), and National Institute of Standards and Technology (NIST).

There are currently 30 forensic art units in law enforcement agencies, universities, and non-profit agencies that employ 55 full-time artists in the United States. There are approximately 20 forensic art units internationally which are similarly distributed among law enforcement, educational institutions, and non-profits or Non-Governmental Organizations (NGOs).

The Forensic Art Discussion Group has developed into an invaluable resource that allows participants to learn from one another, improve their craft, and control the future of their discipline. Positive feedback is continually received from members about the group, which demonstrates the need for such a professional network. The next step is to energize members to improve the profession and increase the perceived and actual value of forensic artists. This is a means of attracting attention to the need for creating and implementing best practices across the discipline and is essential in demonstrating to NIST the need and demand for attention to the forensic art field.

Forensic Art, Communication, Forensic Team Building

E53 National Institute of Justice (NIJ) Programs to Support the Forensic Community: Strategies for Stronger Proposals in a Competitive Environment

Danielle L. McLeod-Henning, MFS, 8137 Loving Forest Court, Springfield, VA 22153; Alan C. Spanbauer, MBA*, 810 7th Street, NW, Washington, DC 20531; and Charles M. Heurich, MFS*, National Institute of Justice, Dept of Justice, OJP, 810 7th Street, NW, Rm 7204, Washington, DC 20531*

The goals of this presentation are to: (1) learn about National Institute of Justice (NIJ) programs that support the forensic science community; (2) learn how to read an NIJ solicitation and what key areas to focus on; and, (3) learn how to write a stronger competitive proposal.

This presentation will impact the forensic science community by providing information about funding opportunities, both competitive and non-competitive, through the NIJ.

There are various types of federal funding opportunities and, generally speaking, they can be broken down into two types: competitive and non-competitive. Non-competitive funding can come in the form of formula grants or sole-source grants/contracts. Competitive funding is just that: competitive. This presentation will focus on competitive funding opportunities issued by the NIJ for research or direct-service assistance related to forensic pathology and medical examiner/coroner services.

This presentation will discuss four programs issued by the NIJ that support the forensic community: (1) Paul Coverdell Forensic Science Improvement Grants Program; (2) Using DNA to Identify the Missing Program; (3) National Missing and Unidentified Persons System (NamUs); and, (4) Research and Development in Forensic Science for Criminal Justice Purposes Program. The NIJ program managers for each of these programs will discuss the specifics of each, including purpose, eligibility, and emphasis on how to write to the selection criteria. Common mistakes and best practices will be reviewed. Requirements including, but not limited to, the program narrative and budget documents will be discussed. A brief overview of NIJ's current forensic pathology research and development and assistance portfolio will also be provided. The goal of this presentation is to provide attendees with an overview of the current NIJ programs that support the forensic science community and to equip attendees with the knowledge and skills to write stronger grant proposals responsive to these programs.

Funding Opportunities, Eligibility, Best Practices

E54 Collaborative Retrospective Research Study Exploring STR and Y-STR DNA on 1,000 Rape Victims: Implications on Practice

Julie L. Valentine, MS, Brigham Young University, 532 SWKT, Provo, UT 84062*

After attending this presentation, attendees will understand the findings from a collaborative retrospective research study on 1,000 rape victims linking data from the sexual assault nurse examiners' forms with data from the state crime laboratory, specifically exploring the findings related to Short Tandem Repeat (STR) and Y-chromosomal Short Tandem Repeat (Y-STR) DNA analysis results.

This presentation will impact the forensic science community by increasing competency for both forensic nurses and scientists on DNA evidence collection and analyses guidelines by presenting the findings from a collaborative, retrospective research study of 1,000 rape victims. It is imperative that these professions work together to establish best practices guidelines for evidence collection in sexual assault cases. The importance of collaboration is reinforced through this retrospective study examining variables affecting positive STR and Y-STR DNA analyses.

Study Proposition: Improvements in DNA analysis methods in sexual assault cases, including Y-STR DNA analysis, have practice implications for forensic nurses and scientists that may be gleaned through a collaborative retrospective study.

Description of Study and Statement of the Methods: The impetus for this research was to explore the impact of enhanced DNA analysis methods, including Y-STR analysis, on crime laboratory findings in sexual assault cases. Implications on evidence collection guidelines in sexual assault cases are also examined in relation to the findings from this study. Practice changes for both forensic nurses and scientists that have occurred due to the findings from this study will be explained.

The setting for the study is a Mountain West urban community in the United States. For each case in the study, 203 variables from the **Sexual Assault Nurse Examiner's** (SANE's) sexual assault examination forms and crime laboratory analysis findings were identified and coded in **Statistical Package for the Social Sciences** (SPSS) statistical software program: 149 variables from the sexual assault examination form and 54 variables from the crime laboratory data on sexual assault kits were returned for analysis.

Summary of the Results: Data analysis is not fully completed, but includes the following points: (1) the percentage of collected sexual assault kits returned by law enforcement to the state crime laboratory for analysis. Preliminary data analysis has found a sexual assault kit return rate of 29.2%; (2) the percentage of returned sexual assault kits to state crime laboratory that underwent DNA analysis. Preliminary data analysis has found 44% of returned sexual assault kits had DNA analysis, with the remaining analyses stopping after serology; (3) descriptive statistics on patients' demographics, suspects' demographics, and relationship of patient to suspect; (4) descriptive statistics on STR and Y-STR DNA analysis findings; and, (5) logistic regression on the following variables — length of time between rape and evidence collection and if patient bathed or showered — on positive DNA profile identification.

Additionally, unusual cases with positive DNA profile identification will be reported as these cases reinforce the importance of expanding DNA evidence collection in sexual assault cases outside of 72 hours between rape and evidence collection.

Implications on Practice/Conclusion: Results from this collaborative study have changed practice guidelines for both forensic nurses and scientists. Preliminary findings from this study have led to the following practice changes: (1) recommended time frame between rape and evidence collection has expanded to five days; (2) biological evidence swabs from body sites other than genital swabs are recommended for collection regardless of whether the patient has bathed or showered; (3) biological evidence swabs from body sites touched by the suspect, in cases of an unknown assailant, are recommended for collection; (4) DNA analysis to be completed on most submitted sexual assault kits prior to serology testing; and, (5) state crime laboratory tracking of all sexual assault kits to determine percentage of kits returned by law enforcement for analysis.

Collaboration, Rape, DNA

E55 Analysis of Suicide Locations in Harris County, Texas

Gavin M. Schmidt, BS*, 1885 Old Spanish Trail, Houston, TX 77054

After attending this presentation, attendees will be aware of the significance of the location chosen by some individuals when they commit suicide through careful examination of the scene and investigation of factors leading up to their death.

This presentation will impact the forensic science community by highlighting the importance of understanding the context and circumstances under which someone takes their own life. By appreciating the significance of the location, forensic practitioners will develop an awareness of how statements and behavior immediately prior to death may relate to the location chosen by the deceased.

While individuals who commit suicide do not always leave notes or other written communication stating their intent, the locations chosen for their suicidal act can often be just as significant. Factors such as religion, financial status, relationship conflicts, and mental illness are common reasons for individuals to commit suicide. Although these factors are often the driving force behind the decision to kill themselves, the location chosen often reflects the significance of those factors.

The jurisdiction of the Harris County Institute of Forensic Sciences (HCIFS) includes the city of Houston and 31 additional law enforcement agencies. According to the 2010 United States Census, the population of Harris County is 4,092,459. Each year, the HCIFS assumes jurisdiction of approximately 4,000 deaths, of which 11%-12% are classified as suicides. The demographic breakdown of individuals who kill themselves has remained constant over the past eight years. The male-to-female ratio is 3-3.5:1 and individuals of White ethnicity are encountered 2.5-3 times more than all other ethnicities combined. The most prevalent method of suicide remains the use of a firearm, followed by hanging and intentional drug toxicities. The largest age demographic is 18-39 years old. These individuals have reached a point in their lives where they are unable to use their present coping skills to address a variety of problems. In cases of spontaneous suicide, the location of their demise typically is opportunistic. In planned suicides, the location of their deaths is specifically chosen, providing clues not only to their thought processes immediately prior to death, but also to the perceived magnitude of their problems.

This presentation will review several suicides in unusual locations in Harris County, TX. An analysis of the location, previous statements made by the individual, and investigative findings will shed light on the significance of the chosen suicide location.

Suicide, Context, Location

E56 Multiple Self-Inflicted Gunshot Wounds: Case Series With a Review of Literature

Avneesh Gupta, MD*, 1300 E Warren Avenue, Detroit, MI 48207; Puneet Setia, MD*, All India Institute of Medical Science, Dept of Forensic Medicine, Jodhpur, INDIA; Vera Mendes-Kramer, MA, 1300 E Warren Avenue, Detroit, MI 48207; Andrea M. Jackson, BA, 1300 E Warren Avenue, Detroit, MI 48207; Kilak Kesha, MD, Wayne County MEO, 1300 E Warren Avenue, Detroit, MI 488207; and Francisco J. Diaz, MD*, 1300 E Warren Avenue, Detroit, MI

After attending this presentation, attendees will understand that a small minority of suicides — less than 1% of all suicides in Wayne and Monroe counties in the state of Michigan — do involve more than one gunshot wound, highlighting that, although rare, the presence of more than one gunshot wound is not a sole hallmark of homicide and requires an open mind when encountering such cases.

This presentation will impact the forensic science community by presenting the largest case series of multiple self-inflicted gunshot wounds. It will specifically impact forensic professionals tasked with determining or assisting in the determination of manner-of-death by reminding them not to immediately rule out suicide in deaths caused by multiple gunshot wounds, whether or not notes are left, as this can occur, evidenced by more than a decade of suicide deaths from a major American metropolitan area.

Suicide by firearm is common and usually ends in a single fatal shot. When two or more gunshots are present, it is frequently viewed as homicide by investigators, police, and the public. This study investigates the incidence, patterns, frequency, and different characteristics of suicide by two or more gunshot wounds, during the period of 2000-2011 in Wayne and Monroe counties. A total of 2,212 cases of suicide were reported and the leading method was by gunshot wound (1,066). Out of those 1,066 cases, there were 17 (1.5%) with multiple gunshot wounds. Nine of these multiple cases had two gunshot wounds and eight cases had more than two gunshot wounds. Fifteen cases involved rifled weapons and two cases involved shotguns. There were two female and 15 male decedents. People 41-50 years of age represented the most suicides involving multiple gunshots. A suicide note was left behind by three (18%) of the decedents, and 14 (82%) did not leave a note. The most common site of entrance was the chest, followed by gunshot wound to the head. In the context of manner-of-death determinations, the characteristics of fatal gunshot wounds along with the importance of keeping an open mind by exploring all physical possibilities during forensic autopsy, are emphasized.

Since multiple gunshots are such a hallmark of homicide, establishing that they are also a fact of suicides is essential, given that Wayne and Monroe counties have a slight rate of occurrence. Of all suicides between 2000 and 2011, less than 1% (17/2,212) had multiple shots. This concurs with Mernerides et al. in noting post-traumatic injury can occur and when it does, may be crucial in differentiating homicide from suicide: *Immediate incapacitation does not occur in every fatal gunshot wound that penetrates the head or perforates the heart.*¹ A study from Lorin on gunshot wounds emphasized the need for careful examination of multiple gunshot wounds for the entrance and exit wounds, estimation of close range, and vital reactions to provide arguments for or against suicidal intent.² A study from Hejna et al. discussed the ability to act in cases of multiple gunshot wounds due to suicide — a frequently asked question during the due course of an investigation and in the courts; the study notes that the character and localization of wounds determine one's ability to act following the gunshot wound.³ Racette et al. reported a rare case of suicide with drowning following two self-inflicted, non-lethal gunshot wounds to the head — this study notes a need for complete and thorough investigation when complex methods for suicide are used.⁴

Suicide, Gunshot, Multiple

E57 Determining the Flow Rate Required to Move Submerged Human Remains

*Jacqueline E. Bleakley, BA**, 1914 Mather Way, Apt A, Elkins Park, PA 19027; *Kimberlee S. Moran, MSc*, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; *Andrea Zaferes, BA*, PO Box 601, Shokan, NY 12481; and *Heather E. Mazzanti, MSFS*, 450 S Easton Road, Glenside, PA 19038

After attending this presentation, attendees will understand some principles of how and under what conditions a deceased human body moves when submerged in a fluvial environment.

This presentation will impact the forensic science community by providing refined search and location strategies for investigations of bodies found in water. The results of this project can augment traditional means of investigation by improving references related to the orientation and velocity of a body on the bottom of a river. Understanding the movement of a body submerged in water can be useful for supporting or disputing witness statements and establishing a timeline of events in an investigation. Models and established patterns of the movement of human remains in water can be used to help determine either information on where a body entered the water once it has been recovered or to aid in searches for missing persons believed to be in the water. This will also be beneficial in stressing the importance of recording the position and orientation of a body found in a river as well as recording the river flow, which is often overlooked by investigators.

This research used two models with densities within the range of that of a healthy adult male: a 12" muslin figurine with water balloons and ¼" zinc nuts, and a 12" muslin figurine filled with silicone and copper rods. The models were submerged alternatively in a racetrack flume that had a one-centimeter layer of fine sand on the bottom and was filled with domestic tap water. Using a pygmy flow meter, the flume was set at a known speed and the model was added. Each model was submerged in four different orientations parallel to the flow of the water: face up with head upstream, face down with head upstream, face up with head downstream, and face down with head downstream. The time it took for the model to travel 100cm was recorded. Additional flow rates were used. The relationship between orientation, flow rate, density, and model velocity was analyzed. For the water balloon model, at the slowest flow rate, the face-up-with-head-downstream orientation moved almost four times faster than any other orientation. At the faster flow, the face-down-with-head-upstream orientation moved half as fast as the other three orientations. Faster flows decreased the significance of the orientation of the model and decreased the flume/model velocity ratio. The silicone model, which had a higher density, required faster flow to reach the same velocity as the water balloon model.

The controlled model was assessed using living human participants who are certified scuba divers. Each participant's height and weight were measured and their density calculated. Each participant lay at the bottom of a river with a pony scuba tank and a dive belt for weight for 15 minutes. Involuntary forward movement and positional changes were observed and the flow of the river was measured with a Price AA flow meter. This was done in three rivers with various sediments on the riverbed.

Drowning, Investigation, Water

E58 A Model for Recovery: Predicting the Location of Human Remains on WWII Bombardment Aircraft Crash Sites

Owen L. O'Leary, MA, JPAC-CIL, 310 Worchester Avenue, Bldg 45, JBPHH, Honolulu, HI 96853*

After attending this presentation, attendees will understand the spatial relationships between human remains and their assigned duty station wreckage within WWII bombardment aircraft crash sites.

This presentation will impact the forensic science community by demonstrating the value of building predictive models from previously examined cases and how that contributes to investigators' abilities to efficiently and effectively recover the remains of individuals in aircraft crashes.

The United States government makes a solemn promise to the men and women of the armed forces that if they fall on the field of battle, their remains will be returned home. In general, Americans demand that this occur in order for the individual to be properly honored and that their remaining family members can find closure. This commitment, and corresponding expectation, applies to both current and past conflicts. The Joint Prisoner of War/Missing in Action Accounting Command (JPAC) is responsible for locating, recovering, and identifying the approximately 90,000 American military personnel who remain missing from the beginning of World War II through the end of the Vietnam War. This presentation details a model based upon JPAC's previously completed casework that predicts where human remains will be found within WWII bombardment crash sites based upon each crew member's individual duty station.

Sixteen WWII bombardment aircraft loss incidents that have been resolved by JPAC since 2000 were assessed for inclusion in the model. Two primary criteria had to be met for a case to be included: (1) the archaeologist who conducted the field recovery had to have recorded the location of the crew duty station wreckage within the recovery scene; and, (2) the field provenience of the remains had to have been maintained through the mitochondrial DNA testing process. A total of eight cases met both of these criteria. Next, the Central Identification Laboratory's (CIL) identification process was run backward through a detailed examination of the skeletal analysis, odontological analysis, mitochondrial DNA, and archaeological recovery reports. Field and laboratory bench notes were also reviewed. This allowed for the determination of where the remains of each crew member were recovered within their respective crash sites in relation to the appropriate corresponding wreckage.

Based upon this, hypotheses were developed for each crew position within the aircraft based upon the patterns observed. The maximum distance that remains can be expected to be found from duty station wreckage varied from 0.8m to 9.4m, depending upon the crew position. Likewise, the maximum distance that remains of a single individual may be spread across a site ranged from 2.7m to 9.0m. The validity of these predictions was then tested against an additional bombardment aircraft loss incident. Overall, results of the testing showed that the hypotheses for each of the duty stations were confirmed and that bombardment aircraft crew members will be found no farther than approximately 8m from their assigned duty station. Additionally, for the cases included in this study, it is determined that the physics of the crash, not the actions of the crew or subsequent erosion, primarily dictates where individuals will be found within a crash site. Beyond the immediate benefits to the effectiveness and efficiency of future JPAC excavations, this study also demonstrates how careful examination of similar types of incidents can result in the ability to build accurate predictive models.

WWII, Bombardment Aircraft, Remains Recovery

E59 From the RFK Assassination in Los Angeles to the Wuornos Serial Killings in Florida: A Preliminary Examination of .22 Fired Casings

Young Wang, 18737 West Place, Artesia, CA 90701*

After attending this presentation, attendees will be aware of the following information: (1) why .22 fired casings are often found at crime scenes, including the assassination of Robert F. Kennedy (RFK) and the Wuornos serial killings in Florida; (2) some unique features of .22 cartridges; and, (3) how to tell the three types of .22 firearms involved from the .22 fired casing at crime scenes.

This presentation will impact the forensic science community by reporting the results from an empirical study of .22 fired casings (N=100). The results provide a nine-category classification of the .22 fired casings by a pistol, a rifle, or a revolver. The study addresses the challenges from the 2009 National Academy of Sciences (NAS) Report, which states that firearms' examination is "not scientific." It is argued that the study can provide crime scene technicians, police officers, school teachers, and students with tools on how to determine the types of .22 weapons used based on the .22 fired casings recovered at the scene.

Shooting incidents are commonly reported by the news media and often the type of fired casing at the scene is the .22 round. This includes the historical assassination of RFK as well as the female serial killer Aileen Wuornos; however, several questions remain unanswered: (1) Why do so many criminals choose the .22 caliber as a murder weapon?; (2) Why does each shooting incident take so long to get solved?; and, (3) Was the criminal considered "smart" or "stupid" for using a .22 firearm? This empirical study involves the analysis of fired .22 casings (N=100) collected from several indoor shooting ranges with marks indicating weapon type as pistol, rifle, or revolver. Under a stereo microscope, each casing was examined and classified into a nine-category reference in terms of the firing pin shape (2D), the depth (3D), and the sloppiness (3D). From the nine-category reference, a practical table is provided illustrating how to differentiate the types of weapons (.22) involved from the types of firing pin shapes observed. Finally, the table is translated into a forensic reference for crime scene technicians, police officers, school teachers, and students.

The .22 ammunition possesses some unique challenges for firearms examinations. First, the .22 casing is the smallest caliber and the firing pin mark is smaller even under a stereo microscopic examination. Second, the .22 cartridge is the only ammunition using the rim firing mechanism with more irregular patterns as firing pin impressions. Finally, the .22 casing is the only cartridge that can be fired by three possible types of weapons, making the caliber-specific rule useless.

Preliminary results can be summarized as follows: (1) Category A were all fired from a revolver since it has a circular impression without any extractor and ejector marks on the casing; (2) Category B were all fired by a pistol. Most firing pins in pistols have a square tip that leaves a square impression on the edge with extractor and ejector marks on the casing; and, (3) Category C were all fired by a rifle, which has a rectangular firing pin tip and uses a much more powerful gas system, thus producing a firing pin impression that is deeper and much clearer than a pistol with the extractor and ejector marks on the wall of the casing.

A modus operandi analysis becomes the final part of the study to answer the question of why the .22 is one of the most popular weapons used by criminals. First, .22 firearms are less expensive weapons than other firearms. Many gang members choose .22 firearms for drive-by shootings. Therefore, the .22 ammunition is widely used by gang members and criminals due to its low cost. Second, .22 firearms (particularly pistols and revolvers) are small in size and thus easier to conceal, which provides necessary convenience in hiding or so-called "ease of concealment." There are more .22s of various types in circulation than any other caliber of firearm. Finally, the .22 casings are a problem in many cases for the crime scene technicians simply because the casing can be fired by three possible weapons, using more time for examination, exclusion/inclusion, and decision. If investigators are unable to identify the type of weapon used in a timely manner at the crime scene, it may hamper the criminal investigation.

The study of the .22 fired casing has several practical implications: (1) an empirical classification can provide a practical protocol for quick determinations at the scene; (2) a valuable tip in differentiating the three types of casings with three unique characteristics from the three .22 firearms (revolvers, pistols, and rifles) can provide school teachers and students with quick determinations for reporting to the police when .22 weapons are involved; and, (3) by employing a new digital device, a quantifiable measurement is developed, supporting the statistical requirement proposed in the 2009 National Academy of Sciences Report entitled, *Strengthening Forensic Science in the United States: A Path Forward*.

Firearms Examination, .22 Fired Casings, Digital Measurement

E60 A Prospective Analysis of the Outcomes of Violent Prone Restraint Incidents in Policing

Darrell L. Ross, PhD, Valdosta State University, 1500 N Patterson Street, 1122 University Center, Valdosta, GA 31698-0060*

The goals of this presentation are to: assess the outcomes of prone positioning of violent subjects by the police, assess the relationship of using restraint techniques and prone positioning of violent subjects, examine the relationship between using electronic control devices and weight applied on the back of a subject by police during restraint and the outcome of the incident, describe the implications of study findings as they impact sudden deaths in custody, and describe recommendations based on the study findings.

This presentation will impact the forensic science community by serving to demonstrate the dynamics of safely using the prone restraint position and force devices used by the police in violent use-of-force confrontations.

Placing a violent subject in the prone position by police officers has been debated since the 1980s. It has been postulated that prone positioning may be hazardous when applied with various populations and may contribute to a sudden death-in-custody based on a theory of restraint asphyxia. Although scientific research contradicts the theory, the debate continues over the use of the prone restraint position. What is not known is how many combative persons are placed in the prone restraint position after the use of varying force modalities used by the police and the outcomes of these violent confrontations. The purpose of this study was to examine the outcomes of the police use of force and the use of the prone restraint position with violent subjects.

Using a prospective research design, officers in 17 police agencies in six states documented the use of the prone position, the use of varying force modalities with combative subjects, and the outcomes of these incidents for one year. Documentation of 1,085 prone incidents was analyzed and the majority of the confrontations involved a male subject. Subjects displayed behaviors consistent with alcohol impairment, mental distress, illicit drug use, or a combination of mental distress/illicit drugs in 85% of the incidents. Over 70% of the subjects were placed and restrained in the prone position from one to five minutes. Seven force modalities were commonly used including handcuffs and hobbles, electronic control devices, subject control techniques, an aerosol, and weight applied on the back of the subject during the restraint incident. No subject died and 80% of the subjects did not sustain an injury.

The findings of this field study confirm previous laboratory research performed on this subject which has indicated the safe use of the prone position. The findings showed that the use of the prone position provides a safe method for controlling, restraining, and securing combative individuals. Recommendations for police officers, police administrators, emergency medical personnel, and forensic investigators are presented.

Prone, Police, Restraints

E61 Biometric Research Database Catalog: Improving Access to Publicly Available Biometric Data Sets

Melissa K. Taylor, BA, 100 Bureau Drive, Gaithersburg, MD 20899; and Shannan Williams, MA*, 100 Bureau Drive, Gaithersburg, MD 20899*

The goal of this presentation is to discuss the existing challenges of making existing databases open to researchers, the development of a centralized catalog to improve access to publicly available databases, and plans to develop a path forward on expanding existing publicly available databases.

This presentation will impact the forensic science community by providing researchers with information about current efforts to expand access to biometric datasets. The Biometric Research Database Catalog will provide the community with a central location to obtain information about publicly available biometric data sets to assist technology development efforts.

Biometrics refers to technologies used for the automated recognition of individuals based on their behavioral and biological characteristics.¹ The most commonly used biometric modalities include fingerprint, palm print, iris, face, voice, and handwriting. Today, biometrics are increasingly used to recognize individuals and regulate access to information, physical space, services, and to cross international borders.² In forensics, biometrics serve a critical function in helping to identify or verify the identity of an individual for crime-solving purposes. The National Institute of Standards and Technology (NIST) has been actively involved in the testing and evaluation of biometrics technologies, starting with fingerprints in the 1960s. This involvement has expanded over the decades to include efforts in various biometric modalities such as fingerprints, palm prints, faces, irises, voices, and handwriting, including the development of a comprehensive biometric data transmission standard.

One challenge to the advancement of biometric technology is the development of test data sets. A number of factors affect the appropriateness of a test data set in evaluating a biometric technology, including whether the dataset is representative of: (1) the subject population; (2) the collection environment; and, (3) the system hardware expected. Researchers need greater access to databases to further studies on distinctiveness and to advance technologies to improve the accuracy and precision of biometric systems.

The purpose of this presentation is inform attendees of the development of a catalog of publicly available datasets by the NIST in coordination with the National Institute of Justice (NIJ). Currently, the catalog contains approximately 200 existing publicly available datasets of various modalities, includes information about the samples via a detailed taxonomy, and serves as a pointer for researchers to obtain access to data supplied by host agencies. The catalog will be used as a basis for discussion among the biometric community to develop a path forward on expanding existing publicly available databases in early 2015.

Biometrics, Fingerprints, Databases

E62 Increasing the Precision of Human Geolocation: A City Scale Investigation of Stable Isotopes in Tap Water

Momoko Ueda*, 8888 University Drive, Burnaby, BC V5A1S6, CANADA; and Lynne S. Bell, PhD, Simon Fraser University, Dept of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA

After attending this presentation, attendees will understand the forensic importance of the isotopic compositions of tap water on a citywide geographical scale for the utilization of stable isotope analysis on human tissues for human provenancing.

This presentation will impact the forensic science community by demonstrating the necessity of understanding the isotopic values of drinking water sources and water distribution systems, at a high geographical resolution, in preference to estimating drinking water values derived from local precipitation water.

The geographical and temporal life history of an individual may be determined by the stable isotope analysis of human tissues. The isotopic compositions of tissues are reflective of the environment in which tissue formation took place, with drinking water being the major contributor for hydrogen and oxygen stable isotopes. Human provenancing through the use of stable isotope analysis becomes possible with the understanding of the isotopic patterns of drinking water across a geographical area, as an isotopic gradient exists for precipitation water across the globe. The term “drinking water” is commonly used interchangeably with both “precipitation” and “tap water” and while the isotopic compositions of tap water is influenced by local precipitation water, the compositions are not necessarily identical. The isotopic distribution of tap water has been previously investigated for the United States, on a large geographical scale, showing the isotopic gradient across the country; however, no previous studies have investigated the isotopic distribution of tap waters across a single city at high resolution.

This study investigated the isotopic distribution of hydrogen and oxygen stable isotopes in tap waters across Metro Vancouver (MV), at a high geographical resolution, to determine whether the isotopic compositions of tap water can vary across a city and, secondarily, can be sourced. MV tap water is supplied by multiple sources with three major watersheds supplying the majority of MV and a complex system of 18 groundwater aquifers providing the remaining areas. Tap water samples were collected from across MV with the help of volunteers during a one-week period in the summer of 2013. Samples were collected in a 30mL airtight glass vial and were stored in a refrigerator until analysis. Triple Liquid Water Isotope Analyzer (TLWIA) was utilized for the isotopic analysis of tap water samples with an instrumental precision of $\pm 0.8\%$ for d^2H and $\pm 0.2\%$ for $d^{18}O$. The Online Isotopes in Precipitation Calculator was utilized for the estimation of isotopic values of local precipitation for MV.

The results revealed that $d^{18}O$ and d^2H in tap water varied across MV with a variation of 5.3‰ for $d^{18}O_{tap}$ and 29.3‰ for d^2H_{tap} . The isotopic compositions of MV tap water were unique to its water source, depending on the water distribution system supplied by multiple water sources, and differed from estimated local precipitation values. This finding has significant forensic importance as MV tap water can be sourced solely by its isotopic compositions and suggests the possibility of ultimately sourcing human values to specific areas within MV, which could aid in forensic investigations by increasing the precision of geolocating human remains. Thus, understanding the isotopic distribution of tap water across a geographical area with high geographical resolution is considered essential for the utilization of stable isotope analysis for human provenancing purposes. It also demonstrates the power of this method and similar studies for all North American cities are recommended.

Stable Isotopes, Tap Water, Human Geolocation

E63 It's Not Over at the Death

Tanya L. Marlow, BS, US Army Criminal Investigation Command, 105 Fenton Circle, Bldg 305, Fort Myer, VA 22211; and T.L. Williams, MFS*, 5 Gabriels Lane, Fredricksburg, VA 22406-8446*

After attending this presentation, attendees will better understand how the United States Army Criminal Investigation Command (CID) Special Agents-in-Charge (SACs) brief family members and the challenges associated with conducting the briefings. This presentation will help make attendees aware of the policies and procedures of conducting casualty liaison briefings based on three case studies which identify the results of casualty briefings to the primary and secondary Next of Kin (NOK).

This presentation will impact the forensic science community by presenting an understanding that once an individual has died, it does not mean the death is over for the family. Understanding and the time it takes to understand the death of the loved one may take years.

In every Army CID office there is a SAC. The SAC is identified as the Casualty Liaison Officer and responsible for contacting and briefing the primary and/or secondary NOK five working days after the official initial notification. After the initial contact is made, the SAC will then contact the NOK every 30 calendar days. The SAC will brief the NOK on the status, any significant changes, or developments in the investigations.

Case Study 1: In 2003, a soldier completed a patrol in Iraq and upon returning to base became agitated with members of his unit. The soldier went to his sleeping area; later the supervisor and others heard a single shot. A thorough investigation, a full autopsy, and a toxicology examination were completed. The death was listed as a suicide by a single gunshot wound to the head. Policies for the CID were different in 2003. The soldier's mother requested information through her congressman, questioning the death investigation. This situation continued for several years as the mother did not accept how her son had died. In 2010, an agent met face-to-face with the mother. At the end of the briefing, the mother indicated she believed her son had committed suicide.

Case Study 2: In 2007, a female soldier with an intra-oral gunshot wound to the head was discovered deceased in an abandoned tent. Days before her death, she was diagnosed with a sexually transmitted disease and discovered her boyfriend no longer wanted to be with her. She gave away several personal items and destroyed others. A thorough investigation, a full autopsy, and a toxicology examination were completed. There were multiple reviews of the investigation by outside agencies and it was determined that the case had been thoroughly investigated. Multiple briefings were given to the family and to congressmen. To this day, her father does not believe his daughter committed suicide and posts on the internet how he believes she was murdered.

Case Study 3: In 2011, a soldier was dating a married woman. When the married woman decided to reconcile with her husband and work on her marriage, the soldier, prior to his death, sent her a text message with a photograph depicting all the medications he was prescribed. A thorough investigation, a full autopsy, and a toxicology examination were completed. The death was listed as suicide by multiple drug toxicity. The investigation revealed multiple searches on his computer regarding how to commit suicide with the drugs he was prescribed and with various over-the-counter drugs. He left a note with suicidal ideations; the laboratory examinations determined the note was in his handwriting and his fingerprints were discovered on the note. He also left a message on his married girlfriend's cell phone. His parents were briefed every 30 days. Approximately nine months after their son's death, the mother still had questions and contacted the CID. The investigation was re-opened to clarify the questions and concerns the mother had. A psychological autopsy was conducted and multiple coordinations were conducted. The investigation was still determined to be a suicide and the mother still questions the results.

As documented in the first case study, the mother indicated that she was not ready for the results of the investigations. As most people realize, there are different stages of grief and everyone processes their grief in a different manner. The CID will answer the family members' questions for as long as they have questions and will use every resource available to assist family members. As long as human nature is involved, there will be questions.

Investigation, Death, Briefing

E64 Detection of Residual Metal on Bone From Bullet Hole Periphery Using Digital Radiography

Brandon Nichols, MD, 2451 Fillingim Street, Mobile, AL 36617; and James A. Bailey, PhD*, Minnesota State University Mankato, 617 Chestnut Street, Wilmington, NC 28401

After attending this presentation, attendees will be familiar with: (1) examining bullet holes in sections of bone using a NOMAD™ X-ray device; (2) reviewing radiographs for the presence of residual metal on bone; and, (3) some of the factors that affect the transfer of metal from the bullet to the periphery of the bullet hole.

This presentation will impact the forensic science community by describing a non-destructive method for identifying possible bullet holes in bone by detecting residual metal around the bullet hole periphery.

Portable X-ray equipment may be used at the scene to examine suspected bullet holes on skeletal remains or fragmented skeletal elements for the presence of residual metal. The examination is not destructive and may provide investigators with preliminary information while the skeletal remains are more thoroughly examined.¹

In this study, sections of bovine bone were cut to 10cm to 18cm in length, then cut longitudinally and used as a substrate for producing bullet holes. The sections of bone were taken to the firing range and shot at a muzzle-to-target distance of approximately one meter with a variety of firearms and ammunition. Four types of firearms were used to produce the bullet holes including: a Smith & Wesson® model 686, a Smith & Wesson® model 5906, a Smith & Wesson® model 617, and a Beretta® model 950. Fifteen brands of ammunition were used which consisted of: eight .22 caliber brands, one .25 caliber brand, three .38 caliber brands, and three 9mm brands. The bullet styles from these brands included: Lead Round Nose (LRN), Hollow Point (HP), Full Metal Jacket (FMJ), and Semi-Jacketed Hollow Point (SJHP).

Eighteen gunshots produced bullet holes. One .22 caliber bullet grazed the bone without producing a bullet hole and the round lead shot from a .38 caliber shot shell produced indentions in the bone without producing a bullet hole. The grazed bullet and the shot from the shot shell both left contact marks on the bone that were gray in color. Some bone samples shattered into multiple pieces and were assembled with the use of shipping tape before making radiographs.

After assembling the bone fragments, radiographs of the bone sections were obtained with the use of a NOMAD™ X-ray device and digital sensor. The NOMAD™ is a hand-held X-ray device powered by a 14.4-volt battery. It has been tested for safety and is approved for use in North Carolina.^{2,3} When the device is energized, the output power for generating X-rays is constant at 2.3mA at 60kVp±10%. The exposure is controlled by adjusting the time on the device. The NOMAD™ has an exposure range of 0.01–0.99sec.⁴ Average exposure time used to obtain radiographs of the bone with bullet holes was 100 milliseconds.

In conclusion, 18 of the 20 bone samples had bullet holes. One bone sample had shot impressions .140 inches in diameter from the .38 caliber shot shell and one sample was grazed with a .22 caliber bullet, both leaving gray marks on the bone. From the 20 bone radiographs examined, 16 (80%) had residual metal on the bone. Of the 18 bullet holes, 15 had metal in the bullet hole periphery. Metal was detected in only one out of five bullet holes when full metal jacketed bullets were fired. Not all bullets transfer metal to bone; however, when metal is transferred, digital radiography is useful in detecting the transfer.

E65 Natural Causes of Death in Young Adults in an Urban Medical Examiner's Office

*Alaa Alsadi, MD**, Rush University Medical Center, 1750 W Harrison, Rm 535 Jelke, Chicago, IL 60612; *Matthew F. Fox, MD**, Rush University Medical Center, 1653 W Congress Parkway, Chicago, IL 60612; and *Steven M. White, MD, PhD*, County Cook OME, 2121 W Harrison Street, Unit D7, Chicago, IL 60612

After attending this presentation, attendees will better understand the incidence and causes of natural deaths in young adults (18-40 years old).

This presentation will impact the forensic science community by providing an overview of the causes of natural deaths in young adults (18-40 years old) in an urban medical examiner's office in Cook County, IL, providing insight into the causes of sudden, unexpected death in this population so risk factors and prevention strategies can be assessed.

In young adults (18-40 years old), natural deaths are less common than accidents, homicide, and suicide. Natural deaths follow a bimodal distribution across the lifespan, peaking in infancy and in the elderly. Sudden, unexpected death in young adults is a significant problem and determining the cause of death in such cases can be challenging. This study was conducted to identify causes of sudden, unexpected death in young adults.

A search of the database of the Cook County Medical Examiner's Office was performed to identify all deaths in people between the ages of 18 and 40 years of age during the years 2011-2013. Within this group, all cases in which the manner of death was listed as "natural" were identified. To focus on cases of sudden, unexpected death in young adults, this study excluded cases with known anatomic causes of death, such as cancer, infections, and asthma that were not due to cardiovascular disease.

Natural deaths accounted for 20% of the cases (775 out of a total of 3,957) in this age range. Of the 775 natural deaths in young adults, 453 (58%) were either cardiovascular-related or had no anatomic cause of death. In the group of 453 decedents, the average age was 31 years, with approximately twice as many males as females. Causes of death were divided into general categories. The most common causes of death were cardiovascular (64.7%), neurological (9.7%), chronic complications of drug or alcohol use (8.2%), metabolic (2.7%), autoimmune (1.1%), genetic (0.4%), and psychiatric (0.2%). Suspected cardiac arrhythmia or unknown natural causes accounted for 13.0% of the cases. Among cardiovascular diseases (n=308), the most common causes of death were hypertensive cardiovascular disease (30%), cardiomyopathy (28%), and atherosclerotic heart disease (17%). Obesity was listed as a contributing cause of death in 24% of the cardiovascular-related deaths. Among neurological diseases (n=48), the most common cause of death was seizure disorder (83%).

Combined cardiovascular and neurological causes of death accounted for 74% of the total natural deaths in young adults. Aside from seizure disorders, cardiovascular-related deaths constituted the majority of cases of sudden death in young adults (18-40 years). This study illustrates that chronic conditions, such as hypertension, coronary artery disease, and obesity, are significant causes of sudden, unexpected deaths in young adults and should serve as targets of prevention and risk reduction strategies in this population.

Sudden Death, Unexpected Death, Young Adults

E66 Body-Found-in-Bathtub Death Investigation

Andrea Zaferes, BA, PO Box 601, Shokan, NY 12481; Dennis J. Chute, MD, Dutchess County MEO, 168 Washington Street, Poughkeepsie, NY 12601; Ani N. Hatza, MS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Kelly A. Moon, 5500 Churchill Lane, Libertyville, IL 60048*

After attending this presentation, attendees will be able to: (1) explain the investigative challenges that are specific to Body-Found-in-Bathtub (BFIB) cases; (2) offer solutions to overcome them; (3) ask critical questions that are frequently overlooked; (4) document and collect evidence that is often unrecognized in BFIB cases; and, (5) use field-tested, investigative protocols and forms which have proven to be effective during a number of cases, including eight BFIB homicide investigations.

This presentation will impact the forensic science community by demonstrating the importance of applying a standardized scientific approach to the investigation of BFIB deaths and by providing law enforcement, death investigators, forensic pathologists, and prosecutors with proven, field-tested protocols to investigate, diagnose, determine, and, if necessary, prosecute BFIB cases.

BFIB cases, which can involve bathtubs, whirlpools, spas, hot tubs, and similar bathing arenas, pose challenges when it comes to recognizing signs of foul play; this is evidenced by the large percentage of BFIB cases in which the manner of death is initially ruled as an accident but, after subsequent investigation, is changed to homicide. These subsequent investigations may not occur until months or years later, when another similar death occurs, life insurance companies raise concerns, or other indices of suspicion emerge.

Initial misdiagnosis in the majority of cases occurs as a result of faulty assumptions made at the scene. Examples include: “cause of death is drowning;” “manner of death is accidental;” “empty pill bottles, so it must be a suicide;” “it makes sense for the decedent to be in a bathtub;” “the toddler drowned due to lack of supervision;” and “a head laceration indicates a slip-and-fall death.”

These assumptions, coupled with the absence of specific BFIB training, can result in an inadequate investigation that misses red flags.

When only benign circumstances are reported in the primary investigation, forensic pathologists may perform a standard autopsy or only an external examination as they lack justification to perform an autopsy more appropriate for a suspicious death. Routine examination may overlook crucial signs of injury, such as posterior neck and back subcutaneous contusions, and prevent investigators and pathologists from spotting incongruities between documented injuries and scene and witness statements.

When the first signs of foul play are recognized at autopsy, such as signs of strangulation, critical scene and witness information may be lost. Sometimes insufficient investigations clear the way to cremations with an irrevocable loss of information.

Drowning as cause-of-death is a diagnosis of exclusion. Preliminary assumptions that a drowning occurred due to intoxication may be disproved days or weeks later, when toxicology results show levels too low for incapacitation. Conversely, positive toxicology findings may erroneously support assumptions of an accidental or suicidal manner-of-death made by investigators who fail to consider that perpetrators may use substances to incapacitate their victims and conceal a homicide. In these instances as well, too much time may elapse before a subsequent investigation, making it difficult to secure scene and witness evidence.

This presentation will include an informative study of more than 300 BFIB cases, including 27 BFIB homicides in at least six states. It will give examples of critical documentation often omitted during scene investigation including: the decedent’s airway position in relation to the water; the state of hand and foot wrinkling; eye-drying artifacts; the degree of witness and bathroom wetness; all evidence of trauma; any evidence of trauma suffered by witnesses; the decedent’s normal bathing habits or lack thereof; water depth and temperature; detailed position and posture information of the decedent when first discovered; and a detailed description of how the decedent was removed from the bathtub.

The presentation will also discuss the importance of performing reconstructions for red-flagged cases to help determine the legitimacy of witness statements; reconstructions have been used in several cases to disprove deceptive witness statements. Lastly, protocols for evidence collection and documentation specific to BFIB cases will be addressed.

Drowning, Bathtub, Homicide

E67 Organization of Scientific Area Committees (OSAC) Forensic Science Standards Activities: Helping Each Other and Stimulating the Future

John Paul Jones II, MBA, National Institute of Standards & Technology, 100 Bureau Drive, Mail Stop 8102, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand many of the essential requirements for developing consensus-based forensic science standards and how the Organization of Scientific Area Committees (OSAC), made up of approximately 600 subject-matter experts, addresses these requirements to support collaboration and stimulate the future.

This presentation will impact the forensic science community by educating attendees on the standards development process, the current status of the OSAC, and instructions on how individuals can become involved with the OSAC and other standards-development efforts.

The development of a quality infrastructure for forensic science was a key component of some of the reforms anticipated in the 2009 National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward*. In response to the Report, the National Institute of Standards and Technology (NIST) and the United States Department of Justice signed a bilateral agency Memorandum of Understanding (MOU) in March 2013 which specified the establishment of “Guidance Groups” now termed Scientific Area Committees (SACs). NIST created the OSAC model to promulgate NIST’s responsibility to administer and coordinate support for the SACs and subcommittees that represent specific forensic science disciplines.

NIST envisions uniform administration of the identification, development, promulgation, and adoption of standards through the OSAC as well as supporting communication flow between the SACs and the forensic science community. The design employs the essential requirements of developing consensus-based standards which include openness, transparency, balance of interest, due process, and an appeals process that ensures each stakeholder’s viewpoints are properly considered. In addition, the OSAC infrastructure will bring a uniform standards recognition platform to the community, enhance scientific rigor, and increase communication among forensic scientists, research scientists, academicians, statisticians, attorneys, managers, and quality assurance specialists. The OSAC structure currently consists of a Forensic Science Standards Board, three resource committees, five scientific area committees, and 23 subcommittees.

Standards, OSAC, Consensus

E68 A Step Toward Likelihood Ratios in Pattern Recognition Disciplines

Simone Gittelson, 100 Bureau Drive, Gaithersburg, MD*

After attending this presentation, attendees will understand how to represent the value of evidence in the form of a likelihood ratio addressing the issue of interest to the court. Attendees will also recognize the important role of probabilities for representing and combining information and uncertainty.

This presentation will impact the forensic science community by providing the attendees with the fundamental principles for interpreting pattern recognition evidence in a logical framework. It will highlight the importance of probabilities in this endeavor. Application of these principles allow the forensic scientist to assign the value of evidence in a transparent and scientific manner.

The role of a forensic scientist is to present the value of scientific observations and analytical results to the court. For this value to be scientifically sound, it should not only be based on scientific knowledge, but also be transparent in how it depends on this knowledge. Hence, subjective judgments and opinions may fulfill the first requirement, but it is difficult for them to fulfill the second. On this second aspect, probabilities provide a framework that allows the scientist to combine different pieces of information in a transparent way.

This presentation explains the fundamental principles of the logical approach to assigning a value to forensic findings in the context of a case. The focus is on pattern-recognition disciplines, yet the basic principles apply to all types of evidence. From a logical perspective, the value of the observed scientific results is determined by the ratio of two probabilities: (1) the probability of the observed results given the prosecution's (or the plaintiff's) position; and, (2) the probability of the observed results given the defense's (or the defendant's) position. This ratio forms what is commonly known as the likelihood ratio. In pattern recognition disciplines, the first probability (i.e., the numerator in the ratio) represents the intra-variability; that is, how the observed features vary if they were produced by the same source, and the second (i.e., the denominator in the ratio) the inter-variability; that is, how the observed features vary if they were produced by different sources in the relevant population of potential sources.

In this presentation, examples will illustrate the basic principles of how to combine numerous pieces of information to assign these probabilities and thus measure the weight of the forensic scientist's findings with regard to the issue of interest to the court. These examples will cover how to combine the value of general characteristics of the observations (i.e., the general pattern of a shoemark or the overall ridge flow of a fingerprint) with the value of specific features (i.e., observations indicating cuts or wear on a shoemark or observed minutiae and pores on a fingerprint), how to choose the most appropriate database to help inform what numerical values to assign to the required probabilities, and how to recognize what additional information is required to assign a probability, and therefore a likelihood ratio, in a particular case. These examples illustrate how a probabilistic framework helps the forensic scientist gather, organize, and present the relevant scientific knowledge in a likelihood ratio addressing the question of interest to the court.

Probability, Likelihood Ratio, Weight of Evidence

E69 Reliability, Validity, Accuracy, and Bias in Forensic Document Examination: An Interdisciplinary Approach to Understanding Forensic Decision-Making Processes and Outcomes

*Mara L. Merlino, PhD**, 1066 Tamworth Lane, Frankfort, KY 40601; *Tierra M. Freeman, PhD**, Kentucky State University, 229 Hathaway Hall, 400 E Main Street, Frankfort, KY 40601; *Veronica B. Dahir, PhD*, University of Nevada, Reno, Grant Sawyer Center for Justice Studies, 1664 N Virginia Street, Mail Stop 0313, Reno, NV 89557; *Victoria Springer, PhD*, 31385 Brae Burn Avenue, Hayward, CA 94544; *Derek L. Hammond, BA*, US Army Criminal Investigation Laboratory, 4930 N 31st Street, Forest Park, GA 30297-5205; *Adrian G. Dyer, PhD*, RMIT University School of Media & Communication, Bldg 5.2.36, City Campus, Melbourne, Victoria 3000, AUSTRALIA; and *Bryan Found, PhD*, Office of the Chief Forensic Scientist, Victoria Police Forensic Services Dept, 31 Forensic Drive, Macleod, Victoria 3085, AUSTRALIA

After attending this presentation, attendees will understand the application of some principles of psychology, the use of eye-tracking technology to study decision-making processes in Forensic Document Examination (FDE), and the potential for this research paradigm to inform other forensic fields.

This presentation will impact the forensic science community by demonstrating the importance of engaging in theoretically based, multidisciplinary research to achieve an understanding of the nature of the methodology and expertise in forensic examinations.

A substantial portion of FDE training is devoted to handwriting and hand printing comparisons. During these comparisons, examiners seek to identify features and characteristics which may be characterized as identifying attributes. The identification — comparison — decision process is common across many forensic areas; examiners first determine the presence or absence of features, then qualitatively assign these features some degree of evidentiary weight to reach their decisions. Examiners are trained to look for both substantial similarities and differences among specimens. The number and quality of these features allow examiners to make assertions about the source of the specimens and the extent of their confidence in their decisions.¹

A substantial body of research addresses the cognitive mechanisms involved in attention and visual search. Many current theories of attention propose that attention is based on the relationship between a bottom-up, saliency-based attentional system and a top-down, feature-specific selection mechanism. Attention is guided by relational information about the target or information about how the irrelevant information of a non-target differs from the features of the target. Relational models of visual search demonstrate that visual attention can be guided by: attending to specific feature values such as color, size, or intensity; inhibiting attention to irrelevant features; or directing attention to how stimuli differ. Relational models place the target in relationship to its context, offering more specific (e.g., directional) information about differences. This relational aspect of attention may be influenced by the presentation formats of stimuli.²

Tversky pointed out that most stimuli seem to be effectively described by the presence or absence of qualitative features.³ He and others argued that an object is represented by a set of features or attributes, and that judgments of similarity are achieved through a process of feature matching. Tversky's "Contrast Model" systematizes this "feature" approach and proposes that similarity depends on the proportion of features common to the two objects and also on their unique features. Feature matching occurs by establishing differences in quality or quantity, such as differences in color or size, or the presence or absence of the features upon which the judgment is based, usually in terms of binary variables. This feature-matching process, along with the deployment of attentional resources, is a core process of forensic document examination.

This presentation discusses the application of psychological theories and methods to understanding the nature of attention, feature extraction and weighting, and decision-making in forensic document examination, and discusses the application of this research paradigm to other forensic areas.

Data from a national study of forensic document examiners (supported by Award No. 2010-DN-BX-K271, awarded by the National Institute of Justice, Office of Justice Programs, U.S. Department of Justice) will be used to illustrate the ways in which cognitive psychology contributed to an understanding of the decision-making processes of experts in the field compared to those of lay people.

Feature Matching, Attention, Interdisciplinary Research

E70 Scientific Area Committee for Physics and Pattern Evidence

R. Austin Hicklin, MS, 3150 Fairview Park, Falls Church, VA 22042*

After attending this presentation, attendees will have gained an understanding of the Scientific Area Committee (SAC) for Physics and Pattern Evidence, which includes the disciplines of friction ridge, firearms and tool marks, questioned documents, footwear and tire tread, and blood stain pattern analysis.

This presentation will impact the forensic science community by educating attendees on the standards development process and the role of the SAC for Physics and Pattern Evidence within that process.

The Physics/Pattern SAC will provide direction and oversight for the five subcommittees; interface with the resource committees (Human Factors, Legal Resource, and Quality Infrastructure); communicate activities, progress, and recommendations; review, facilitate public comment, and approve standards and guidelines; and coordinate research priorities.

The subcommittees that address each of these five disciplines will include subject matter experts who will develop and vet standards and guidelines regarding that discipline's techniques, protocols, validation of new techniques, test methods and materials, terminology, and training; will define requirements for accreditation and certification; will develop research priorities; and will coordinate the transition of existing Scientific Working Group (SWG) documents into approved standards or guidelines. These subcommittees nominally correspond to the current scientific working groups Scientific Working Group on Friction Ridge Analysis, Study, and Technology (SWGFAST), Scientific Working Group for Firearms and Tool Marks (SWGGUN), Scientific Working Group for Forensic Document Examination (SWGDOC), Scientific Working Group for Shoeprint and Tire Tread Evidence (SWGTREAD), and Scientific Working Group on Bloodstain Pattern Analysis (SWGSTAIN).

The intent of the Physics/Pattern SAC and subcommittees is to foster the development of rigorous standards and guidelines within and across these disciplines, to assist in the adoption and enforcement of these standards and guidelines, and to encourage research and evaluation to test and validate these methods. The ultimate purpose is to enhance the actual and perceived rigor of these disciplines through transparent, accurate, and reliable processes.

Standards, OSAC, SAC

E71 Objective and Quantifiable Metrics for the Determination of Latent Print “Suitability”

Henry J. Swofford, MSFS, 4930 N 31st Street, Forest Park, GA 30297; Anthony Koertner, BS, US Army Criminal Investigation Laboratory, 4930 N 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will: (1) be introduced to a novel technology, developed by the Defense Forensic Science Center, capable of measuring relevant image quality metrics of fingerprints; (2) understand the association of fingerprint image quality metrics and examiner performance during comparison exercises; and, (3) understand how this approach can be utilized to standardize “suitability” decisions and enhance quality assurance systems in fingerprint units nationwide.

This presentation will impact the forensic science community by introducing a more objective approach for determining “value” or “suitability” of latent fingerprint images.

Latent print examiners are routinely faced with the challenge of making determinations of “value” or “suitability” during the analysis phase of latent print examination. In the United States, there is no formal criterion for basing “suitability” determinations other than the subjective opinion of the examiner. Analyses of latent print images and the determinations of “suitability” consist of two major process steps, both of which are undertaken by the analyst without advanced instrumentation: (1) the visual analysis of the fingerprint image, assessing clarity, contrast, acutance, and other relevant image quality metrics associated with friction skin impressions in an effort to visually detect relevant features which may be used for comparison; and, (2) the consideration of the significance and reliability of that data detected for subsequent comparison and determination of “identification” or “exclusion” to a particular source.

Being a subjective process, determinations of “suitability” are susceptible to intra- and inter-analyst variations — especially for those “borderline” impressions having limited or lower quality detail. In an effort to minimize such variations and provide objective, quantifiable criterion upon which to base suitability determinations, novel fingerprint image quality assessment software has been developed to analyze the quality of fingerprint images and associate quality scores to analyst performance during comparison exercises. Such information will provide a more robust and standardized framework for dealing with “suitability” determinations, which is rooted in empirically derived data versus the vaguely defined and subjective approach of examiner opinion. Having such capability not only provides objective metrics to support analysts’ “suitability” decisions, but also provides a means by which laboratories may monitor training progress and assess performance of latent print personnel. The results of preliminary evaluations and policy guidelines which may be developed from these data will be presented along with the potential for transferring this type of technology approach to other pattern evidence disciplines.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army, United States Department of Defense, or United States Department of Justice.

Latent Prints, Suitability, Sufficiency

E72 Cognitive Profiling of Latent Fingerprint Examiners

Itiel Dror, PhD, University College London, Center for the Forensic Sciences, 35 Tavistock Square, London, England WC1H 9EZ, UNITED KINGDOM; and Melissa K. Taylor, BA, 100 Bureau Drive, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand the background research that underpins the development of this cognitive profile for fingerprint examiners.

This presentation will impact the forensic science community by showing the forensic community how to identify applicants that have the aptitudes, experience, and skills needed to succeed in latent print examination.

Experts are characterized by specific and special abilities. Cognitive abilities are the mental skills necessary to accomplish a particular task. The accumulation of these specific cognitive abilities represents the general cognitive profile or “skill toolbox” which is needed to successfully perform the tasks required in a specific expert domain. In some cases, determining which cognitive abilities are important for a profession appears to be common sense. Forensic laboratory managers need to know whether applicants have the aptitudes, experience, and skills needed to succeed in latent print examination. For example, the ability to accurately detect sometimes small similarities or differences between two visual images appears to be important to the task of latent fingerprint examination. Therefore, examiners who possess the ability to make visual comparisons consistently and efficiently will be able to perform their job; however, “visual comparison abilities” is very broad and general, and vague from a cognitive perspective. Furthermore, as with all expertise, not all cognitive abilities are as obvious and even the expert may not be able to articulate all the mental skills that are important for the role. For example, professional racing drivers may not be able to articulate precisely how they know when to apply the brakes when approaching a corner; it just “feels right.” This, sometimes, is the nature of expertise. Correct characterization and quantification of these cognitive profiles enable better selection and screening at recruitment, and provide a very cost-effective tool for management. They can also be used as benchmark indicators and to test for job performance potential and effectiveness. In addition, such cognitive profiles provide clear targets for skill development.

Cognitive profiling has been used in several domains including military pilots and security X-ray screeners. To help in the selection of latent print examiners, the National Institute of Standards and Technology (NIST) in collaboration with the Federal Bureau of Investigation (FBI) supported the development of a test that quantifies the cognitive processes that underpin fingerprint examinations. The details of the abilities needed for forensic latent print examination is described at www.testcogpro.com. In order to develop suitable tools to measure cognitive abilities, professionals must better understand and define the nature and critical elements of expertise. This can be done through interviews, detailed task analysis, and scientific experimentation. This presentation will provide an overview of the background research that underpins the development of this cognitive profile for fingerprint examiners. The presentation will also provide a demonstration of the test instruments constructed to measure an individual’s level of aptitude for these skills.

Cognitive Profile, Special Abilities, Latent Prints

E73 Tips for the Courtroom: How to Get the Most Out of the Expert Witness

*Stephanie Domitrovich, JD, PhD**, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501; and *Jeffrey M. Jentzen, MD**, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109

After attending this presentation, attendees will be better prepared to select the expert witness to assist and advise them as legal counsel for their clients' cases. Attendees will learn from an experienced judge and practicing forensic pathologist, the value of the expert witness to provide technical advice to legal counsel concerning the facts and theories to be anticipated from the opposing counsel. After discussing the case with an expert, counsel will be better able to construct effective pleadings and focus counsel's attention on the relevant issues in the case. Attendees will also learn ways to locate and select the most qualified experts available. The presenters will also discuss the value of preparing the expert rather than coaching the expert so that the expert is testifying objectively and truthfully.

This presentation will impact the forensic science community by equipping lawyers to work with the expert witnesses. Lawyers will become aware of the value of the multifaceted role that an expert plays by contributing vital input in the initial stages of their cases and the importance of selecting the best expert to address the main issues in the case. Lawyers will learn of the ethical responsibilities to provide objective and unbiased testimony to the court regardless of affiliation or remuneration.

Attorneys should select and obtain experts in the early stages of the litigation process in order to reserve the best expert for the specific case and so that the expert can assist and advise counsel as to major issues of the case as soon as possible. Professional organizations may be excellent sources for obtaining qualified experts; however, counsel must proceed with caution and evaluate the requirements for membership in those organizations. Attorneys should carefully evaluate each expert's credentials such as education, professional licenses, academic and teaching appointments, publications, experience in their field of study, previous expert testimony, professional disciplinary actions, criminal record, any relationship to the parties, and any financial interest in the outcome of the case.

The scientific expert witness has a role as an educator both for the attorney's education as well as to assist the jury in understanding the scientific issues of the case. To be effective, this should occur during preparation for trial and not in the courtroom. It is difficult to test expert testimony at trial without advance notice and preparation. The courtroom is where the attorney, with the expert's help, educates the jury, not where the attorney encounters difficult scientific questions for the first time. The experts should explain facts based on information and knowledge available without entering into an advocacy role. Experts educate attorneys about their field of technical or professional expertise involved in the case.

In this presentation, forensic pathology is the scientific field used to illustrate best practices in preparing for the courtroom and selecting and effectively utilizing the expert. Experts may have limitations due to their field of expertise. Forensic pathologists, for example, may have possible limitations on their ability to be experts such as when they are estimating time-of-death, questions related to toxicology, or other related scientific fields. Experts should not be encouraged to stray outside their field of expertise.

Attorneys should also consider the importance of the demeanor of the expert, such as the expert's professional image, ability to communicate effectively to the jurors, skill and effectiveness with demonstrative evidence, ease in a courtroom environment, and the ability to not appear too relaxed so as not to project disrespect or a "hired gun" image. The expert should be polite and candid as well as appearing confident in responses and displaying patience and competence. The expert cannot speculate. Both attorneys and experts should avoid mispronouncing medical and legal terms. Attorneys should discuss with their experts the legal meanings of such terms as *reasonable medical certainty*, *beyond a reasonable doubt*, and *preponderance of the evidence*.

Attorneys should provide all facts of the case to their expert to avoid "ambush" by the opposing counsel. Experts enable counsel to be able to pose the critical questions to opposing experts in confronting contested issues of a particular case. A well-prepared expert is also better able to perform in the courtroom since he/she can analyze and organize the facts in a way that jurors can comprehend. Counsel should conduct a simulated cross-examination to optimally prepare the expert witness. Counsel should explain anticipated trial procedures, schedules, as well as trial technique and strategies to get the most out of the expert.

Expert Witness, Courtroom Preparation, Medical Testimony

F1 A Study of More Than 400 Case Reports Between 2009 and 2014, Completed in the Venice Surveillance Court to Understand, Evaluate, and Investigate the Social Hazards on the Judicial Level of Subjects Convicted of a Crime

*Vincenzo Lusa, JD**, Via Ferdinando, Palasciano #72, Rome 00151, ITALY; *Patrizia Trapella, JD**, via Cavour 24, Rovigo, ITALY; *Luca Massaro, MD**, via degli Artigiani n° 4 ESTE (PD), Este (PD) 35042, ITALY; and *Sara Raponi**, Via Mario Fioretti 18, Rome 00152, ITALY

After attending this presentation, attendees will be able to distinguish what legal and scientific bases in Italy form the concept of social danger from a criminal (Article 203 of the Italian Penal Code: a dangerous person is one who, even if healthy or incompetent, has committed crimes and is likely to commit new crimes) by citing an unpublished study of 400 case-specific reports from 2009 through 2014 belonging to the largest surveillance court for social dangers in northern Italy: the Court of Venice.

This presentation will impact the forensic science community by informing attendees, through the cases studied, which scientific parameters (neuroscience and behavior) and jurisprudence present the criminal's personality and how the Tribunal of Venice works to understand, assess, and contain the danger presented by the offender.

From this study arises a new vision of social danger determined by a new protocol on the individual criminal by combining the results obtained on the progress of neurosciences with the personalities, the environment, and the history of the offender through the cases studied. In Italy, it is the Surveillance Court judge who acts on those convicted after the sentence is finalized and who decides on requests for alternative punishments to prison such as home detention, early release, and provisional custody to social services. It includes statistics on how a judge in Italy makes a prognosis as to the danger to society, both in terms of the risk of re-offending as well as the personality of the suspect. In this study, the alternative punishment requests have been correlated (probation with the social service, home detention, and parole) and the concept of "social danger" by an analysis covering a sample of people, mostly men of Italian and foreign nationalities. The average age is between 30 and 65 years old.

From the Court of Venice results, it is possible to say that the social danger, in cases of rejected requests for alternative measures to prison, is manifested by a complete absence of reflection on the part of the convicted person in regard to their crimes and behavior prior to the offense as well as lack of participation in social activities, violent conduct committed in prison demonstrating the presence of violent and aggressive personalities in some prisoners. The case studies seem to confirm the importance that the environment exerts on the criminal and this is also demonstrated in both neuroscientific studies and criminogenesis made on humans from a criminal anthropological perspective. In fact, the gene pool can be modified for "random variations" from which mutations can derive, "random changes" (genetic drift), and migration influx; therefore, mutations can be beneficial or detrimental and selection will favor the human ability to adapt and as such has influenced evolution of the adaptive formation of new alleles. In genetics, the study of some alleles has led to the understanding that there is a relationship between genetics and crimes through the examination of some neurotransmitters such as monoamines, including serotonin and dopamine, whose biological effects are regulated by enzymes such as Monoamine Oxidase A (MAOA), (MAOA-L allele), and Catechol-O-Methyl Transferase (COMT). These two alleles have determined a reduction of the penalty in two trials in Italy.¹ Serotonin regulates impulsive-aggressive behavior and its alterations are at the base of the aggressiveness; these alleles (including allele-s) determine a lower capacity for adaptation and therefore generate aggressive behavior. In addition to these concepts, the personality of the offender must be taken into consideration. Indeed, the environment originates the character of the offender as a result of temperament (hereditary biological matrix) and the environment where the criminal lives or has lived (including social and family environments) and this is judged by an Italian judge. Another criteria concerns the biology and structure of the brain influenced by environment and evolution. Granting house arrest (in other words, semi-liberty) to criminals has proven to the Surveillance Court of Venice to be the best method to limit social danger.

Social Dangerousness, Criminal Law, Neuroscience

F2 An Evaluation of a Crime During a Trial in View of Cesare Lombroso's Scientific Insights on the 180th Anniversary of His Birth: This Scientist's Ideas Representing the Scientific Roots of the Evaluation of a Criminal's Personality Contained in the Italian Penal Code

Vincenzo Lusa, JD, Via Ferdinando, Palasciano #72, Rome 00151, ITALY; and Annarita Franza, PhD, Via delle Oche 15, Florence, ITALY*

After attending this presentation, attendees will learn the scientific basis of articles in the Italian Criminal Code (Rocco Code, 1930) related to a criminal's personality, which originated from the Italian Positivist School (19th century) and from the ideas of Cesare Lombroso (1835-1909).

This presentation will impact the forensic science community by acquainting attendees with the introduction of Lombroso's insights into modern Italian criminal trials, which have led to the development of criminal jurisprudence related to neuroscience (e.g., the Bayout trial in Italy, 2010).

Lombroso's book *The Criminal Man* (1876) contains his insights, which are limited to the science of his times. A composite work, *The Criminal Man* collects nearly two decades of studies on criminals. These observations led Lombroso to the differential diagnosis among normal, insane, and criminal subjects (*Introduction to the Clinical Course on Mental Diseases*, 1863; *The Man of Genius*, 1864) and the formulation of an experimental research method in which criminal cases were included. For many years, Lombroso conducted research on the existence of somatic and cerebral brain abnormalities among criminals and the insane (*Some Cases of Lesions of the Central Nervous System*, 1861; *Supernumerary Cerebral Convolutions in a Murder and Satyrist*, 1871). After other contributions on such important cases of forensic psychiatry, like the Verzeni and Agnoletti murder trials (*Verzeni e Agnoletti studiati dal prof. Cesare Lombroso*, 1873) and the publication of *Anthropometry of 400 Venetian Criminals* (1872) and *Emotions and Passions of Criminals* (1874), Lombroso illustrated the correlation between somatic stigmata and mental deformities in reference to specific factors (atavism, epileptoidism). Lombroso saw illicit criminal behavior as an "organic fatality" that drew certain people to commit crimes. Following these ideas in the Italian penal code, articles were created to prevent criminal behavior through neutralization and control structures and by combining therapy with penal sanctions (e.g., Article 203, Italian Criminal Code).

Current research into the biological causes of crime has revealed such important legal and criminological aspects as genetics during trials and what is intended as a neurobiological explanation of criminal behavior. In fact, neuroimaging and brain imaging analyses (Computed Tomography (CT), Magnetic Resonance Imaging (MRI), **Positron Emission Tomography** (PET), and functional Magnetic Resonance Imaging (fMRI)) have shown reductions in the brain's structural and functional parts among subjects prone to violent behavior, leaving them unable to feel emotions and empathy, calling to mind Lombroso's morally insane. In fact, the necessity of assessing whether the criminal impulse is a possible adaptive response to the environment has been noted. The gene pool can be modified for "random variations" from which mutations can drift and "random changes" (genetic drift) migration influx. Indeed, mutations can be beneficial or detrimental with selection favoring the human ability to adapt and this has influenced evolution in the adaptive formation of new alleles. The offender's personality should also be added to these concepts. In fact, the offender's environment gives rise to his character as a result of the union between temperament (defined as the hereditary biological matrix), and the social/family context. As regards the environmental impact on one's body, epigenetics, which associates genes and environment, also regulates gene expression rather than the same gene's mutation. Another criterion concerns evolutionary influence on the brain's biology and structure. In genetics, the study of some alleles has enabled an understanding of the relationship between genetics and crime through the examination of such neurotransmitters as monoamines, including serotonin and dopamine, whose biological effects are regulated by enzymes: (e.g., Monoamine Oxidase (MAO) (MOA-L allele) and Catechol-O-Methyl Transferase (COMT)). Serotonin regulates impulsive-aggressive behavior and its alterations are the base of the aggressiveness; its alleles (including allele-s) determine a lower capacity for adaptation therefore generating aggressive behavior.

Because of Lombroso, the current Italian Criminal Code contains articles defining dangers to society (art. 203), attribution (art. 85), tendencies to commit a crime (art. 108), criminal recidivism (art. 99), and the habitual criminal offender (art. 102). Italian trial case reports related to Lombroso's observations have been used to illustrate all of this (Bayout trial in 2009, Albertani trial in 2011, and the Cremona trial in 2012).

F3 **Can Parents Inherit the Sperm of the Deceased Son? Presentation of an Italian Case and Review of the European Legislation in the Field of Postmortem Fecundation**

*Simona Napoletano, MD**, Viale Regina Elena 336, Rome, ITALY; *Mariantonia Di Sanzo, Viale Regina Elena 336, Rome, ITALY*; *Francesco P. Busardo, MD, via del vespro, 129, Palermo, ITALY*; *Enrico Marinelli, PhD, viale Regina Elena, 336, Roma, ITALY*; and *Simona Zaami, PhD, viale Regina Elena, 336, Rome 00161, ITALY*

After attending this presentation, attendees will better understand European legislation in the field of postmortem fertilization and how the legal framework regarding the use of sperm after a donor's death is still controversial.

This presentation will impact the forensic science community by providing the current legal status of sperm and its right to be inherited by relatives in the case of a donor's death.

Introduction: A recent Italian case provided the opportunity for many considerations regarding postmortem fertilization and the use of sperm after the donor's death. Numerous questions should be answered; in particular, the legal concept of sperm, if it can be inherited, and who has the right to determine the semen's destination. May the donor, by written consent, relatives of the deceased, and/or other institutions, such as the sperm bank, be involved?

The Case: Prior to undergoing chemotherapy, a 20-year-old man affected by a lymphoma decided to preserve his gametes for future fatherhood in the sperm bank of a Roman hospital. Unfortunately, the man died shortly after and his parents asked for the return of his seminal fluid from the sperm bank where it was stored. The request was denied because the hospital stated that only the interested party may have his gametes returned and the right to restitution is not transmissible to heirs because the ownership of gametes is a personal non-transferable right. The parents therefore decided to pursue litigation. In January of 2012, the Ordinance of the Court of Rome decreed that the only limitation, which may arise in the recognition of the applicant's right to succeed their son in collecting the sample, is that the parents cannot use the seminal fluid for procreative purposes. This limit is not an impediment as long as it is possible, before delivery, to make the semen unsuitable for fertilization. The Court then gave an injunction ordering the hospital to prolong the cryopreservation. The final judgment of the Court of Rome on June 2013 did not agree with the motivations reported in the previous ordinance, stating that the right of restitution has to be independent from a possible illegal use, which will be banned only if it will occur. Finally, the Court concluded affirming that the most important right, which has to be protected, is the interest of the parents to have a relic of their son and therefore it ordered the restitution of the seminal fluid to the family.

Discussion and Conclusions: This case is an example of how, in Italy, the use of biological material intended for the use of procreation is a problem which is still far from being solved. Even in countries where postmortem fertilization is strictly prohibited, such as Italy, the legislative vacuum often leads to different, very questionable interpretations that sometimes can be in conflict with current legislation. The use of sperm after a donor's death remains a very controversial issue; among European Union states, only a few countries allow this practice for purposes of procreation, with different degrees of freedom (Belgium, Greece, Spain, and United Kingdom), whereas in the majority of the remaining European Union members, this practice is either strictly prohibited or, alternatively, there is no specific regulation in this field.

Postmortem Fecundation, Donor's Death, European Legislation

F4 Moderate Force Blunt Trauma to the Head Leading to Coma: The Role of the Medicolegal Expert in the Assessment of Attempted Murder Charges

Sara Hemied, MD, Viale Regina Elena 336, Rome 00161, ITALY; Alessandro di Luca, MD, Viale Regina Elena, 336, Rome 00161, ITALY; Giorgia Ciancolini, via ex ospedale n. 10, Ronciglione (VT), ITALY; Irene Catarinozzi, MD, Viale Regina Elena 336, Rome 00161, ITALY; and Natale Mario di Luca, MD, Viale Regina Elena 336, Rome 00161, ITALY*

After attending this presentation, attendees will understand the numerous difficulties in establishing a causal link between moderate use of force by the accused and serious life-threatening consequences for the victim.

This presentation will impact the forensic science community by explaining the difficulty of some rare cases wherein the role of the forensic expert is crucial in establishing the nature of the prosecution.

In both civil and common law, a profound difference can be found between the accusation of personal injuries and attempted murder in terms of the significance of accusation and consequent punishment. In most jurisdictions, the sentence may vary from a few months to several years in prison. One of the various cases in which the forensic examiner plays a key role in law proceedings is when, on the basis of the fact analysis and the injuries sustained by the victim, he is called to express an opinion about the exact charge, of the accused on behalf of the court.

The case reported here occurred just outside a nightclub in the historic center of Rome, where a young man was attacked for petty reasons by four men of the same age. The victim received several blows to the face with a scooter helmet. When the man reached the hospital, the physicians diagnosed three compound fractures, one each to the left eye socket, the nasal bones, and the left jaw. The man also reported that he had experienced several episodes of headache and vertigo in the days prior to the assault. A magnetic resonance imaging of the brain was performed, revealing the presence of a tumor-like formation surrounded by a vast area of hemorrhage. Histological exams were performed and revealed that the aforesaid formation was actually a World Health Organization Class II oligodendroglioma. Guidelines indicate that surgery resection should be performed on such neo-formation, yet the rupture of the capillary vessels of the tumor itself constitute an impassable contraindication. The man was treated with a decompressing craniotomy as a consequence of the massive bleeding and compression. The patient fell into a coma and six months later was declared to be in a persistent vegetative state. As shown by the facts, a modest series of blows (although delivered with an improvised weapon) caused the victim to fall in a serious near-dead state. The main matter of inquiry for the medicolegal experts was the assessment of the causal link between the blow dealt by the assailants and the consequences suffered by the victim. As “per se,” the strike with an improvised weapon had only provoked some marginally important fractures, yet the hemorrhage caused by the rupture of the oligodendroglioma capillary vessels led to the coma. In this case, the medicolegal experts informed the judge that the assailants were to be charged with attempted murder. Even though the victim was already suffering from the brain tumor, his condition had deteriorated due to the criminal act and there had been a significant decline in his chances of healing.

Attempted Murder, Oligodendroglioma, Legal Medicine

Jurisprudence Section - 2015

F5 The Long Road to Exoneration for Han Tak Lee

John J. Lentini, BA, Scientific Fire Analysis, LLC, 88005 Overseas Highway, #10-134, Islamorada, FL 33036*

After attending this presentation, attendees will understand some of the major changes that have occurred in fire investigation over the last 30 years and will see how, in addition to the science of fire investigation having shifted, the definition of “new evidence” also appears to have shifted.

This presentation will impact the forensic science community by making known the significant scientific and legal changes that are sweeping through the fire investigation profession.

Han Tak Lee was convicted in 1990 of setting a fire that killed his 21-year-old daughter, Ji Yun Lee. Mr. Lee had taken his daughter to a Korean Baptist camp in Hebron, PA, because she was having serious mental health issues. He hoped that the demons could be “prayed away” from his daughter and an actual exorcism was performed.

On the evening of their arrival, after Ms. Lee stated, “This place is going to be my tomb,” a fire erupted in the cabin they were sharing. Mr. Lee was able to escape, but his daughter was not. She had only 9% carboxyhemoglobin in her blood at the time the reading was taken, erroneously as it turns out, as a sign that she had been murdered or placed “at death’s door,” rather than the now-accepted explanation that she was close to the origin of the fire. Investigators from the Pennsylvania State Police and a private consultant came to the scene and declared the cause of the fire to be arson. The private consultant estimated that there had been 662+ gallons of fuel oil and 12.2 pounds of gasoline, even though none of the debris samples were positive for any ignitable liquid residue.

Some ignitable liquid was found on Mr. Lee’s shirt and next to the filter for the kerosene-fired furnace. The state’s chemist, when asked if the ignitable liquid residues he detected on three samples were similar, evaded the question and stated, “They covered the same carbon number range.” The prosecutor then argued that the three ignitable liquid residues were identical and because Mr. Lee’s defense was that the daughter had set the fire, the prosecutor argued that somebody had mixed the accelerants together and a mentally ill girl was not smart enough to do that.

Over the next 21 years, Mr. Lee, who had been sentenced to life in prison, continued to serve his life sentence. After many back-and-forth trips to court, including a five-year hiatus during which the state simply ignored the case and refused to respond, the Third Circuit Court of Appeals ruled that the evidence must be given up for reanalysis. It turns out that the chromatography, which could have been examined back in the early 1990s when it was first requested had been “lost” by the district attorney, who had inexplicably taken custody of this data which would normally have been stored in a state archive. Testing of the samples in 2012 revealed significant differences among the three samples and undermined the argument that somebody had mixed up several gallons of accelerant prior to the fire.

The original fire investigation was replete with the types of errors that were common in those days, as well as some additional errors that defy understanding.

The final ruling, issued June 13, 2014, by Magistrate Judge Martin Carlson gives meaning to the term “poetic justice.”

Arson Mythology, Expert Errors, New Science

F6 Misinterpretation of Common Fire Behaviors and Its Effect on Criminal and Civil Litigation

Steven W. Carman, MS, Carman & Associates Fire Investigation, Inc, PO Box 273, Grass Valley, CA 95945*

The goals of this presentation are to: (1) increase awareness of the propensity for misinterpretation of the effects of commonly encountered fire scenarios leading to improper conclusions as to fire origin; (2) demonstrate useful techniques to identify fire-spread behaviors; and, (3) expand awareness of frequent mistakes made in investigating common fire scenarios.

This presentation will impact the forensic science community by increasing awareness of misinterpretation of fire scene evidence which will reduce the likelihood of baseless litigation in both criminal and civil cases.

For more than 20 years, the fire investigation community has undergone a metamorphosis, transitioning from widespread adherence to an art-based investigative approach to a more science-based style. Historically, explanations offered to explain the creation of burn patterns were based less on scientific fact than on anecdotal beliefs.^{1,2} Guidance from documents such as the National Fire Protection Association (NFPA) 921, Guide to Fire and Explosion Investigation and other references along with training and certification programs have emphasized reliance on scientific principles and have nudged investigators along that path of change.³ Interim developments in federal case law also now require that fire investigation be based on solid scientific principles rather than novel, untested techniques.

In 2005, while presenting a seminar on fire dynamics, Special Agents from the United States Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) designed an exercise to evaluate the information relied upon by investigators in identifying fire origins. Two identical, bedroom-size burn cells were each burned for seven minutes, reaching full fire involvement. Fifty-three fire investigators who had not observed the fires briefly examined the cells to identify which quadrant of the cells they thought each fire had started. Upon evaluating the first cell, only three of 53 investigators (5.7%) correctly selected the quadrant of fire origin. The same percentage (although different investigators) correctly identified the quadrant-of-origin in the second cell.⁴

In similar exercises conducted over the previous 16 years at the Federal Law Enforcement Training Center in Georgia, only 8%-10% of students correctly located the origins of fully involved fires. Investigators not identifying the correct origins typically reported being misled by burn patterns generated during full involvement under ventilation-limited conditions. This was despite such conditions frequently occurring in structure fires.

Follow-on studies of ventilation-limited fires were conducted in places such as the ATF Fire Research Laboratory in Amundale, MD, and elsewhere. Computer analyses have been used to study such fire behaviors and to explain ventilation flows and the related fire spread. Examination of heat flux, temperature, and gas concentration data as well as the burn patterns have enabled better understanding of the various mechanisms involved. Transfer of such information to the fire investigation community, albeit a seemingly slow process at times, is crucial for improving the accuracy of fire origin determinations.⁵

Several regularly encountered fire scenarios have been shown to result in conditions often at odds with commonly accepted ideas. One such popular belief is that the area of worst fire destruction is indicative of the place the fire burned the longest. Post-flashover and elevated fires are examples of scenarios where this idea is frequently proven wrong. In each case, areas of extensive fire damage may be generated well apart from the origin and misinterpreted as being the actual origin. Techniques such as computer modeling are available to test hypotheses but their use remains limited.⁶⁻⁸

Examples of actual investigations will be discussed in which the behaviors of such fires were misinterpreted. In at least two instances, homicide charges were proposed in suspected arson fires later shown to have started on a stovetop. Incorrect fire cause determinations behind convictions that were later overturned will also be reviewed.

F7 A Perfect Storm Brewing for Fire Investigators in Court

*Terry-Dawn Hewitt, LLM**, McKenna Hewitt, 9057 E Mississippi Avenue, #11-206, Denver, CO 80247; and *Wayne J. McKenna, LLB*, McKenna Hewitt, 9057 E Mississippi Avenue, #11-206, Denver, CO 80247

After attending this presentation, attendees will understand the significance of three forces that are converging into a perfect storm for fire investigators. Included will be an explanation of the hypothesis that the culmination of these three forces is resulting in a reinvigoration of challenges based on the Supreme Court decision in *Daubert v. Merrell Dow Pharmaceuticals Inc.* (or state equivalents), including heightened inquiry into the extent of subjectivity and bias by experts in fire cases.

This presentation will impact the forensic science community by providing information relevant to anyone involved with civil or criminal fire litigation. Extensive research has been conducted into cases across the United States and Canada where industry standards such as the National Fire Protection Association (NFPA) 921 are used in court to either support or challenge expert testimony. This research has revealed trends toward a closer scrutiny of the reliability of expert testimony and sufficiency of experts' qualifications. The detailed description of these trends (as supported by this presentation) provides attorneys, judges, and fire experts with a road map for ways to deal with fire experts in court. Even though the 2009 National Academy of Sciences (NAS) Report devoted but a short paragraph to fire investigations, attendees will learn why it is responsible for a huge impetus toward closer scrutiny of the qualifications and opinions of experts in fire cases. Together, the NAS Report, growing publicity about wrongful convictions in arson cases, and changes in industry standards for fire investigators are putting fire experts under a microscope. This presentation will help members of both the legal and the fire investigations communities to prepare for the perfect storm on the horizon that is being precipitated by these factors.

This presentation will review the three forces behind the big changes in the offing for fire investigators: (1) the ongoing movement by courts across America to scrutinize more closely the reliability of expert testimony under *Daubert* and its progeny; (2) a growing apprehension about wrongful convictions stemming from faulty forensic evidence and problems in fire investigations culminating in the revolutionary 2009 NAS Report, *Strengthening Forensic Science in the United States: A Path Forward*; and, (3) the continuing development of industry standards that are raising the bar for fire investigators, particularly revisions in the 2014 editions of NFPA 1033, *Standard for Professional Qualifications for Fire Investigator* and NFPA 921, *Guide for Fire and Explosion Investigations*.

This presentation will first explain the growing demand that experts be able to demonstrate the reliability of their opinions in court under *Daubert* and its state equivalents. Next, the problems caused by faulty forensic science, including weaknesses in fire investigations and the response by various sectors of American society to address these problems will be considered. The responses have come in the form of reports examining weaknesses in forensic science and fire investigations, together with recommendations to address these issues. The most significant of these reports are highlighted from the viewpoint of their importance to the fire investigation field.

Finally, this presentation will address the heart of this study's hypothesis and describe how these three forces are converging and causing a reinvigoration of *Daubert*. First to be considered is why *Daubert* and its progeny continue to have an influence in the coming of the perfect storm, even though investigators have had two decades to learn how to deal with *Daubert* challenges. The reasons why fire investigators have weathered the first part of the *Daubert* storm, but need to prepare for the next onslaught will be proposed. Further, an explanation of how the NAS Report and other forensic science reports are increasing pressure on investigators, thereby strengthening the potential of reliability inquiries under *Daubert* and its progeny will be presented. The session will conclude with recommendations for fire investigators planning to give expert testimony in court.

NFPA 921, NAS Report, Daubert

F8 Next-Gen Is Now: Legal Implications and Strategic Preparation for Massively Parallel DNA Sequencing in Forensic Science

Ted R. Hunt, JD, Jackson County Courthouse, 415 E 12th Street, Fl 7M, Kansas City, MO 64106*

After attending this presentation, attendees will understand the critical importance of multidisciplinary collaboration for the development and implementation of legal authorization and for making strategic preparations for Massively Parallel Sequencing (MPS) technologies.

This presentation will impact the forensic science community by explaining the legal and strategic challenges, opportunities, and potential threats to the forensic application of this cutting-edge technology and how these factors can be most effectively addressed through a coordinated interdisciplinary approach.

The forensic implementation of MPS has the potential to cause a sea of change in the criminal justice system's response to DNA evidence. This is because the technology has the capability to reveal an extraordinary constellation of genetic information about not only identity, but also the phenotypic characteristics, ancestry, lineage, and genetic predispositions of those associated with a criminal offense. It also has the potential to deconvolute currently indiscernible mixtures and detect genetic profiles from samples too degraded for fragment length-based detection methods.

It is precisely *because of* these new and distinctively different capabilities that the potential of MPS for criminal justice applications cannot be fully realized without the counsel and coordination of those both within and outside the forensic community. This includes attorneys, ethicists, policy makers, and industry leaders, among others. Importantly, this coordination must begin *now*, before critical choices are made about the forensic application of MPS that may ultimately prove to be legally indefensible or socially unacceptable.

From a legal perspective, statutory schemes that address constitutional concerns about law enforcement's collection, detection, retention, and comparison of sensitive genetic information must be drafted, debated, and enacted. This legislation must be adequate to withstand the heightened scrutiny that courts will surely apply to the Fourth Amendment "secondary search" analysis applicable to the detection and retention of the genetic data generated by MPS technologies.

State and federal legislation concerning the admissibility and use of DNA evidence in the legal system, which was largely drafted by law makers and interpreted by the courts in response to fragment length detection methods, must be reevaluated and revised to address the unique capabilities and concerns relevant to next generation sequencing technologies.

Existing legislation that prohibits the unauthorized dissemination and use of genetic information in government databases must also be considered and revised, as appropriate, to adequately address heightened ethical and privacy concerns applicable to this sensitive data.

From a strategic perspective, cases that cannot currently be solved with existing DNA technologies may well be cracked in the future by MPS analysis. As such, investigations now facing a forensic DNA impasse may be good candidates for future cold case review projects utilizing MPS. Therefore, America's crime laboratories must *currently* begin to systematically identify and document those forensic samples in their archives that are indiscernibly mixed or too degraded to yield a profile in response to contemporary testing technologies. This work must begin immediately to prevent future time-consuming and tedious retrospective searches for candidate MPS case samples. In other words, laboratories must stop throwing any more "needles" into the "haystack."

Crime laboratories, in consultation with law enforcement and prosecutors, must carefully weigh the risk of currently consuming challenging samples with present-day DNA technologies against the benefit of waiting to test that evidence with MPS-based systems. This dilemma is similar to the decisions labs faced in the past about whether to risk sample consumption with **Restriction Fragment Length Polymorphism** (RFLP) testing or wait for emerging Polymerase Chain Reaction (PCR) technologies.

Finally, evidence, case files, and third-party records from unsolved investigations that involve challenging forensic samples must be identified, properly preserved, and archived by crime labs, police agencies, and prosecutors. This will help ensure that these essential elements of a successful prosecution, a valid defense, or a meaningful post-conviction DNA analysis can be used to credibly support future judicial findings of guilt or innocence based on next generation technologies.

Massively Parallel Sequencing, Legal Implications, Strategic Preparation

Jurisprudence Section - 2015

F9 The National Commission on Forensic Science: Status Update

*Nelson Santos, MPA**, 700 Army Navy Drive, Arlington, VA 22202; and *John M. Butler, PhD**, NIST, 100 Bureau Drive, MS 4701, Gaithersburg, MD 20899

After attending this presentation, attendees will better understand the activities of the National Commission on Forensic Science during the past year.

This presentation will impact the forensic science community by providing an update on the progress made by the National Commission on Forensic Science throughout its first year.

The development of a quality infrastructure for forensic science was a key component of some of the reforms anticipated in the 2009 National Academy of Sciences (NAS) Report entitled, *Strengthening Forensic Science in the United States: A Path Forward*. In response to the NAS Report, the National Institute of Standards and Technology (NIST) and the United States Department of Justice (DOJ) announced an interagency initiative to enhance forensic science which specified the establishment of a National Commission on Forensic Science (NCFS) and the development of “Guidance Groups” now termed Scientific Area Committees (SACs).

DOJ and NIST announced the membership in January 2014 and have since held five meetings in Washington, DC, (February 2014, May 2014, August 2014, October 2014, and January 2015). From more than 300 applicants, 37 individuals were selected to achieve a diversity of experiences, including: forensic science service providers; research scientists and academicians; prosecutors, defense attorneys, and judges; law enforcement; victim advocates; and other relevant stakeholders. The Commission is led by Co-Chairs Mr. James Cole, Deputy Attorney General, and Dr. Willie May, NIST Director and Under Secretary of Commerce for Standards and Technology. Nelson Santos, Deputy Assistant Administrator for the Office of Forensic Sciences at the Drug Enforcement Administration and Dr. John Butler, Special Assistant to the Director for Forensic Science, serve as the DOJ and NIST Vice-Chairs, respectively. The NCFS has seven subcommittees on the following issues: (1) Accreditation and Proficiency Testing; (2) Reporting and Testimony; (3) Scientific Inquiry and Research; (4) Training on Science and Law; (5) Interim Solutions; (6) Medicolegal Death Investigation; and, (7) Human Factors. All NCFS meetings are open to the public and materials are available at <http://www.justice.gov/ncfs>.

NIST developed the Organization of Scientific Area Committees (OSAC) to administer and coordinate support for the discipline-specific SACs (see <http://www.nist.gov/forensics/osac.cfm>). In September 2013, NIST issued a Notice of Inquiry (NOI) in the Federal Register to obtain national and international input on the establishment and structure of governance models. Eighty-two submissions were received in response to the NOI. The OSAC is designed to provide uniform administration for development, promulgation, and adoption of documentary standards in the forensic science community.

While NCFS is a DOJ advisory group to enact policies, OSAC will be an on-going community effort to improve forensic practices through developing documentary standards that can be used by accrediting bodies in future audits of forensic laboratories. This presentation will review progress made with NCFS. OSAC progress will be the subject of a separate presentation.

National Commission, NAS Report, Federal Advisory Committee

Jurisprudence Section - 2015

F10 **Leading a Horse to Water and Trying to Make Him Think: The Impact of the 2009 National Academy of Sciences Report (NAS) Report, *Strengthening Forensic Sciences in the United States: A Path Forward on America's Courts***

*Pamela A.W. King, JD**, 400 S Broadway, Ste 15, Rochester, MN 55904; and *Christine Funk, JD*, Department of Forensic Sciences, 401 E Street, SW, Washington, DC 20024

After attending this presentation, attendees will understand how the 2009 National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward* has been received by the judiciary and has impacted the court system.

This presentation will impact the forensic science community by focusing on how cases around the country have addressed the NAS Report. It will describe how, in large part, the judiciary has found evidence to be admissible despite the concerns raised. This presentation will explore why the judiciary has been resistant to considering issues highlighted by the Report and why a more deliberate approach would be beneficial.

In February 2009, when the Committee on Identifying the Needs of the Forensic Science Community issued their report, *Strengthening Forensic Science in the United States: A Path Forward*, it raised serious concerns regarding the scientific underpinning of certain forensic disciplines, resulting in speculation about what impact this would have on forensic and legal communities.

The intent was “to chart an agenda for progress in the forensic science community and its scientific disciplines.”¹ Recommendations focused on reform to the forensic community, not the impact to the court system. How would the criminal justice system be impacted? One professor suggested, “The findings in the National Academy of Sciences report should spur judges to require higher standards.”²

Although not focused on legal reform, in March of 2009, the Committee Co-Chair said he expected, “courts [would] take the findings of the committee regarding the scientific foundation of particular types of forensic evidence into account when considering the admissibility of such evidence in a particular case.”³

In June, the United States Supreme Court cited this Report stating, “The forensic science system, encompassing both research and practice, has serious problems that can only be addressed by a national commitment to overhaul the current structure that supports the forensic science community in this country,” thus further suggesting that judicial review of the committee’s concerns might be warranted.⁴

As the Committee Co-Chair predicted, courts have been asked to address how the concerns raised by the NAS Report impact the admissibility of forensic evidence including fingerprints, ballistics, and hair comparison. Other cases addressed claims of ineffective assistance of counsel and newly discovered evidence.

Despite multiple challenges, case law suggests there has been little effect on how courts assess forensic evidence and written opinions tend to be cursory. Forensic evidence has rarely been deemed inadmissible. Courts have been reticent to engage in careful discussion of whether the concerns of the NAS Report are legitimate and, if so, what modifications to the admissibility of evidence are required to insure the integrity of the system. The changes the courts have made are usually in the form of limitations on the scope of expert testimony.

The court system has an important role, assuring the reliability and integrity of forensic science used in criminal cases that leads to the conviction of the guilty and the exoneration of the innocent. That is why the issues raised by the NAS affect the entire forensic family: defense attorneys, prosecutors, judges, and practicing scientists.

In 2010, the Committee Co-Chair said, “[T]here is still much more that can be done by members of the legal profession, bench and bar, within the existing legal framework, to insure that forensic evidence is properly assessed and admitted only when it will serve the ends of justice. If we insist on valid and reliable forensic methodologies and practices, and qualified practitioners, change will happen. And our systems of law enforcement and criminal justice will be better for it.”⁵

F11 Forensic Science Leaders on the Path Forward

Sarah Chu, MS, 40 Worth Street, Ste 701, New York, NY 10075*

After attending this presentation, attendees will understand the various efforts advanced by the forensic science community and supported by the Innocence Project that can be implemented by laboratories to advance forensic science.

This presentation will impact the forensic science community by identifying and sharing model efforts that forensic science leaders have implemented in their laboratories.

In 2009, the National Academy of Sciences published an authoritative Report on the state of forensic science in the United States. The forensic science community advocated for this Report and leaders within the community began to advance policies and strategies to improve forensic science even before the publication of the Report. While members of this community may disagree on aspects of this Report entitled, *Strengthening Forensic Science in the United States: A Path Forward*, the Report has served to broaden the national conversation on forensic science, emphasize the critical need to act urgently, and has also served as a rallying point for federal resources.

In the six years since the release of the NAS Report, a number of developments have been driven by its release. Eight hearings in the Science and Judiciary Committees of both houses spurred discussions that have resulted in the introduction of three bills in the 113th Congress focused on establishing a federal infrastructure to support forensic science. Additionally, the Department of Justice (DOJ) and the National Institute of Standards and Technology (NIST) entered into a Memorandum of Understanding (MOU) to collaborate in the creation of a National Commission on Forensic Science (NCFS) and a forensic science standards setting infrastructure now named the Organization of Scientific Area Committees (OSAC). The creation of the NCFS was announced in February 2013, its members were appointed, and the first meeting held in February 2014. While the NCFS is co-chaired by NIST and DOJ, its organizational center is within the DOJ. NIST and DOJ are also collaborating on the establishment of the OSAC. Appointments of OSAC members are in process. To date, the appointments have incorporated members of the relevant scientific communities and their standards-setting work was anticipated to begin before the end of 2014.

Many recommendations of the NAS Report, such as research funding and setting national standards, can only be accomplished or are most efficiently addressed at the federal level. Among issues that can be effectively addressed at the state, local, or laboratory level are those that focus on quality assurance and quality control, processes to address cognitive bias, and improvements to transparency. This presentation will focus on strategies that specific laboratories or forensic science groups have developed to address these issues in the absence of national standards and policy recommendations from the NCFS. Among the efforts that may be highlighted are the implementation of root cause analyses, comprehensive reporting, and transparency measures. These accomplishments are notable in that these forensic science leaders are proactively advancing their laboratories' scientific practice which will better prepare them for them for the road ahead.

Policy, Laboratory Quality, NAS Report

Jurisprudence Section - 2015

F12 Got Forensic Science Standards? — How the Organization of Scientific Area Committees (OSAC) Activities *COULD* Impact the Courtroom...

Mark D. Stolorow, MS, MBA, NIST Office of Special Programs, Organization of Scientific Area Committees, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899-8102*

After attending this presentation, attendees will understand how the efforts of more than 600 subject-matter experts (volunteers) appointed to the Organization of Scientific Area Committees (OSAC) and others could impact laboratory protocols, accreditation efforts, and testimony in forensic science.

This presentation will impact the forensic science community by educating attendees on the processes employed by the OSAC to identify, foster the development of, and formally approve forensic science standards through publication on the OSAC Registration of Approved Standards and Registry of Approved Guidelines. These standards development efforts will ultimately affect methods employed in forensic science laboratories, standards used during the accreditation process, report writing, and testimony offered by experts.

As the forensic science community is aware, the development of a quality infrastructure for forensic science was a key component of some of the reforms anticipated in the 2009 National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward*. In response to the Report, the National Institute of Standards and Technology (NIST) and the United States Department of Justice signed a bilateral agency Memorandum of Understanding (MOU) in March 2013 which specified the establishment of “Guidance Groups,” now termed Scientific Area Committees (SACs). NIST created the Organization of Scientific Area Committees (OSAC) model to promulgate NIST’s responsibility to administer and coordinate support for the SACs and subcommittees that represent specific forensic science disciplines.

The consensus-based documentary standards and guidelines approved for posting on the OSAC Registry of Approved Standards and Registry of Approved Guidelines will be considered: (1) by laboratories as standard methods for specific analyses; (2) as potential discipline-specific standards for consideration by accrediting bodies offering accreditation services in the forensic industry; and, (3) by officers of the court when evaluating processes employed and testimony given by forensic science experts.

The OSAC design employs the essential requirements of developing consensus-based standards which include openness, transparency, balance of interest, due process, and an appeals process that ensures each stakeholder’s viewpoints are properly considered. In addition, the OSAC infrastructure will bring a uniform standards recognition platform to the community, enhance scientific rigor, and increase communication among forensic scientists, research scientists, academicians, statisticians, attorneys, managers, and quality assurance specialists. The OSAC structure currently consists of a Forensic Science Standards Board, three resource committees, five scientific area committees, and 23 subcommittees.

Standards, OSAC, Testimony

Jurisprudence Section - 2015

F13 Strawberry Fields Forever: How a 73-Year-Old Birdwatcher Helped Nab a Sexual Predator in Central Park

Melissa Mourges, JD, New York County District Attorney's Office, One Hogan Place, New York, NY 10013; and Martha Bashford, JD*, New York County District Attorney's Office, One Hogan Place, New York, NY 10013*

After attending this presentation, attendees will learn how a good samaritan who took pictures of a deviant predator was later viciously sexually assaulted by this same man as punishment for her actions.

This presentation will impact the forensic science community by illustrating how the quick thinking of a crime victim and quick actions by the police led to the apprehension of a rapist and the collection of five different types of evidence leading to his conviction.

Beth B. is a dyed-in-the-wool New Yorker, a dedicated nature lover, and feisty as hell. At 73, she routinely walked through New York City's Central Park, enjoying the weather and taking pictures of birds. In September 2012, though, she saw something very disturbing through her camera lens — a heavily tattooed, creepy-looking man who was openly masturbating in the park. Beth took a picture of his face, in case he caused trouble.

Two weeks later, she was back in the park near Strawberry Fields (made famous as a tribute to Beatle John Lennon) with her camera. A man approached her. "Remember me?" he asked. She said no, but in fact, she remembered him well — he was the sinister man whose photo she had snapped earlier in the month. She walked away from him as quickly as she could, but he jumped on her back, pulled her to the ground, choked her, and pounded her face into the dirt. In broad daylight, he raped and sodomized her, then told her to count to 100. He fled through the park, taking her camera bag with him.

Beth reported the crime and went to the hospital, where a sexual assault evidence kit was taken. Surveillance cameras in the park caught the man moving away from the crime scene, and an All Points Bulletin went out. Patrol officers caught 42-year-old David Mitchell several hours later, still wearing the clothes he had on during the attack.

Beth picked him out of a lineup. Nevertheless, Mitchell claimed HE was the victim — of mistaken identification — and insisted the police had the wrong man. Because Mitchell was caught so soon after the crime, investigators took the unusual step of having doctors complete a "suspect evidence kit" including swabs from the defendant's genitals, looking for evidence of rape. Although police never found the stolen camera, computer forensics experts were able to recover Beth's photos, which she had downloaded, but deleted, two weeks before.

Mitchell, it turns out, had a frightening history. A drifter who terrified the other homeless people living in the park, Mitchell had confessed to the murder of his West Virginia neighbor, an 83-year-old widow, when he was only 16. He was acquitted after a psychiatrist said he was too cognitively impaired to understand either his rights or his confession. He was later charged with raping and robbing another woman in her 70s and pleaded guilty to robbery charges in that case. He then served eight years in jail for abducting yet another woman.

Attendees will see the evidence, learn how it was recovered, and what it proved. Actions of the quick-thinking and courageous victim, with an assist from video, computer forensics, and DNA, put a career criminal behind bars, far away from New York City's back yard, Central Park.

Sexual Predator, Photographs, New York City

F14 Mental Maps: Why You Should Worry

Katherine Ramsland, PhD, DeSales University, 2755 Station Avenue, Center Valley, PA 18034*

After attending this presentation, attendees will recognize how a personal Cognitive Positioning System (CPS) affects legal decision-making and case analysis.

This presentation will impact the forensic science community by illustrating the need to be educated about mental defaults that subconsciously filter information and distort judgments that guide decisions.

A CPS develops from experience and education, both of which are filtered through the brain's cognitive defaults. A person's CPS is their personal perspective, which is comprised of a unique network of influences and shortcuts that affect (and infect) mental processing. All interpretations and subsequent decisions are made within this frame. Everyone prefers familiarity, simplicity, and closure, and their mindsets comply with the feeling, "That's right!" This can hinder thorough analysis.

For example, in an experiment, 50 homicide investigators and 68 undergraduates were given evidence from a homicide case and offered two potential hypotheses. The students showed bias in accord with their initial hypothesis, but were open to disconfirming evidence. Investigators — especially those with a high need for closure — were more likely to automatically view evidence as incriminating. They accepted disconfirming evidence *only* if it aligned with their initial hypothesis.¹

Contrary to common belief, rational thinking is not automatic. Some information goes through rational channels and some through intuitive channels. The latter are faster, so they have the first impact. Intuitive responses are automatic, subconscious, and highly influenced by emotion. Conclusions form quickly, without analysis. Thus, they are vulnerable to the errors that form from personal bias and limited experience or education.

Everyone makes automatic judgments from within their frames of reference. Constructs learned from social and familial milieu, such as gender roles, rules of thumb, and racial stereotypes, have a significant subconscious impact on how the world is seen. Repeated experience with these constructs forms mental schemas. Then situations are "scripted" with construct-specific expectations.

These constructs feed into mental maps.² "Mental mapping" describes how people become habituated to their perspective. It goes by other names, such as cognitive map, perceptual set, or frame of reference. Individuals encode, recall, and recognize their "situated existence" according to a familiar frame. That is, people learn things from their families, culture, and subcultures that subtly thread throughout their personal interpretations.

How the world is physically and emotionally processed with mental maps guides people's decisions and behaviors. The brain then links perceptual sets with physiological systems, so that habits become encoded. This "embodied cognition" or "body memory" explains "gut feelings." Individuals allow even uninformed notions to guide them.³

However, what *feels* right is not necessarily right. Gut instinct can become a threshold diagnosis that averts a full analysis. People tend to see what they expect to see, and their recall is usually more consistent with personal beliefs and feelings than with facts, especially as it supports an intuitive hypothesis. Contradictory information is generally ignored. Sometimes, it is not even perceived.⁴

In sum: Research in cognitive psychology shows that certain types of mental maps present a persistent challenge for those involved in the legal/investigative process. Investigators arrive at scenes with mental maps that frame their investigation (or lack thereof).⁵ Attorneys, judges, and jurors approach cases via their personal CPS. This presentation will identify common cognitive biases and offer suggestions for minimizing their damaging impact.⁶

Jurisprudence Section - 2015

F15 Three Shots to the Head: A Case Study of a Murder Prosecution in Indiana

Christine Haskell, JD, 128 N Cullen Street, Rensselaer, IN 47978*

After attending this presentation, attendees will understand the importance of collecting and analyzing forensic evidence present at a murder scene and the importance of the forensic evidence used by the prosecutor in the eventual prosecution against the accused.

This presentation will impact the forensic science community by providing a case example of the importance of collecting forensic evidence by law enforcement officers, the processing of that evidence, and explaining the results of the analysis to ensure that the prosecutor's case is sound. In addition, it will demonstrate how important it is to utilize multiple forensic science disciplines to corroborate the theory of the prosecution's case. The case example will illustrate how vital it is for the prosecutor to have a firm understanding of the science in order to comprehend the implications of the forensic scientists' conclusions.

The primary goal of this presentation is to present a case study of a homicide prosecution in a rural county in Indiana. In this particular case study, law enforcement officers responded to a call from a young woman who reported that her brother had been shot. When law enforcement arrived, the victim was found lying dead on his bed with a wound to his head. The officers moved the body to see if medical attention could be rendered and to try to locate a weapon. When no firearm was located, the officers contacted a crime scene technician and began processing the scene as a homicide. Emphasis was placed on how the body was positioned when the sister and the first responding officer initially entered the bedroom. The crime scene technician arrived and processed the scene, collecting forensic evidence for analysis, specifically photographs of blood spatter patterns on the wall and the bedding with which the individual was covered. Law enforcement officers continued the investigation of the crime by questioning friends and relatives. In addition, an autopsy was performed and it was concluded that the victim had been shot in the head three times. In addition, toxicology results revealed the victim tested positive for various chemical substances in his body. Also, law enforcement officers located a firearm believed to be the murder weapon. Subsequently, a firearm examiner performed bullet comparison tests to determine if this was the murder weapon. The weapon that was used in the crime was a .22 caliber single-shot bolt-action rifle, which required the manual placing of a cartridge into the chamber for each shot. Law enforcement officers identified a person as the murder suspect. He was arrested, but claimed self-defense; however, based on the conclusions derived from the toxicology results, the blood spatter patterns, and the operating mechanism of the firearm, this claim was definitely not plausible.

With the corroborating forensic evidence from several forensic science disciplines, the prosecution was able to refute the claim of self-defense, which resulted in the accused pleading guilty to the murder.

Criminal Justice, Evidence Collection, Case Study

F16 How an Innocent Person's DNA Turned Up at a Murder Scene: Case Study of Lukis Anderson

Kelley Kulick, JD, Office of the Public Defender, 120 W Mission Street, San Jose, CA 95110*

After attending this presentation, attendees will have a basic understanding of primary, secondary, and tertiary transfer of DNA and how inadvertent transfer relates to criminal cases. The goal of this presentation is to review a case in which inadvertent, secondary transfer of DNA evidence in a homicide led to the arrest, accusation, and incarceration of an innocent man.

The facts of the case study confirm the reality that inadvertent transfer does indeed occur in criminal cases. This presentation will impact the forensic science community by raising questions about the likelihood and ease of inadvertent transfer of DNA and how the increased sensitivity of DNA testing heightens the risk that small amounts of transfer DNA from innocent people will be detected. This presentation also serves to educate lawyers, judges, law enforcement, and experts about the serious risks inherent in the introduction of DNA match evidence into an investigation and ultimately the courtroom, when corroborating evidence is weak or nonexistent.

Sometime between 10:30 p.m. on November 29, 2012, and 1:35 a.m. on November 30, 2012, assailants entered the home of Harinder and Raveesh Kumra. The couple were beaten, bound, and gagged as the home was ransacked. Mr. Kumra died from asphyxiation as a result of the binding and gagging. The prosecution alleged that the murder was committed by Lukis Anderson and three other African American co-defendants. The state charged Mr. Anderson with murder and the special circumstance of a murder in the course of a robbery, making him eligible for the death penalty. He was also charged with robbery, assault with a deadly weapon, terrorist threats, and false imprisonment.

During the police investigation, fingernail clippings of the right hand of the decedent were collected for forensic testing. A mixture of DNA from at least three individuals was detected in the swab of these clippings. Both Raveesh and Harinder Kumra were included as possible contributors to this mixture of DNA. On December 21, 2012, the remaining DNA types were searched against the Combined DNA Index System (CODIS) which returned a match for Mr. Anderson. The county crime laboratory calculated the random match probability for this DNA as 11,000 to 1 for African Americans.

The prosecution's case against Mr. Anderson rested entirely on the DNA evidence. The surviving victim was unable to identify the perpetrators. Even under great pressure, Mr. Anderson never confessed. The prosecution took great efforts to try to connect Mr. Anderson to the other co-defendants, but Mr. Anderson was an outlier.

Defense investigation revealed that on the night of the homicide, a clerk called the police to report that Mr. Anderson was intoxicated in front of a market. The local fire department was the first responder to the call and arrived on scene at 10:29 p.m. The paramedics determined that Mr. Anderson was unable to care for himself so an ambulance transported Mr. Anderson to the county hospital at 10:45 p.m. Mr. Anderson's blood alcohol level was approximately .41 when he arrived at the emergency room. This level was consistent with his fully intoxicated state of being non-ambulatory, flaccid, and totally somnolent. Mr. Anderson was not discharged from the hospital until the next morning at 9:50 a.m., well after the crime was committed.

Based on the presentation of hospital records and defense interviews of pertinent witnesses, the prosecution dismissed all charges against Mr. Anderson after he spent five months in custody. Further investigation by the prosecution showed that the ambulance that transported Mr. Anderson to the hospital was the same ambulance that responded to the homicide. In addition, the pulse oximeter applied to Mr. Anderson's finger to monitor oxygen saturation was also applied to the decedent's finger and is thought to be the source of the secondary DNA transfer.

Without the presentation of the documentary evidence establishing a complete alibi, Mr. Anderson would likely have been convicted of capital murder. This presentation will be an opportunity to learn and discuss the far-reaching implications of inadvertent transfer of DNA in criminal trials.

DNA, Inadvertent Transfer, Bias

Jurisprudence Section - 2015

F17 Crime Scene Investigator: Assessment of Expert Credentials

Kevin J. Parmelee, MPA, Somerset County Prosecutor's Office, Forensic Lab, 40 N Bridge Street, Somerville, NJ 08876*

After attending this presentation, attendees will be provided with a thought-provoking evaluation of the many variables that are considered for the determination of a Crime Scene Investigator (CSI) as an expert for the court. Variable perspectives will highlight the many aspects of a CSI's qualifications when considered as an expert witness. Information will include regional variations in the qualifications required to become a CSI, disparity between the qualifications of CSIs in large urban agencies vs. smaller rural agencies, comparison between sworn law enforcement officers vs. civilian CSIs, and an assessment of certified vs. non-certified practitioners.

This presentation will impact the forensic science community by highlighting the many facets considered when identifying the qualifications necessary for a CSI to be distinguished as an expert witness.

After the first responding patrol officer arrives at a crime scene, the CSI is commonly the first individual specially trained to conduct an in-depth investigation for recognizing the value of relationships between statements, physical evidence, and crime scene observations. In particular, the CSI functions to recognize, document, collect, and preserve relevant physical evidence in order to generate a representation of events and circumstances about the crime. The information, physical evidence, and data obtained from a successful crime scene investigation provide the preliminary basis for any subsequent forensic investigations, testing, and analysis. Essentially, the CSI establishes framework for which the investigation, both criminal and scientific, is based. With such a large responsibility for providing a successful crime scene investigation, there would appear to be the expectation that the CSI is specially trained and proficient in his or her skills. So what qualifications would be used in the determination of a CSI as an expert witness in court?

Job descriptions from various regions of the United States represent a disparity in the requirements sought to perform the duties of the position. Furthermore, the demands and resources of larger, more urban agencies may represent a significant difference from smaller, more rural agencies. There are organizations that provide certification options for CSIs, but does a certification provide all that is necessary? Does the lack of a certification eliminate a candidate from providing expert testimony? These variables and inquiries will be reviewed to generate thought-provoking and insightful dialog.

Crime Scene Investigator, Expert Witness, Expert Credentials

Jurisprudence Section - 2015

F18 Root Cause Analysis for Attorneys: Why? Why? Why? Why? Why?

Max M. Houck, PhD*, Consolidated Forensic Laboratory, 401 E Street, SW, Washington, DC 20024

After attending this presentation, attendees will understand the basics of root cause analysis as a tool for exploring potential failures of forensic service providers.

The presentation will impact the forensic science community by providing attorneys with a valid framework for inquiries directed at actual or perceived failures of forensic service providers. This framework will help the forensic science community respond to legal inquiries in a structured, focused manner.

Root Cause Analysis (RCA) is a method of problem-solving that tries to identify the necessary and sufficient reasons for an event, typically a fault, problem, or — in this case — a non-conformity in a quality system. Once a root cause is removed from the sequence, the non-conformity should be prevented from happening again.¹ RCA assumes that systems and events are related. An action in one area can create other actions or results in others, continuing on in what is known as the “causal chain.” RCA traces the remnants of the chain of events back to its source, the root cause.

RCA is an iterative process.² The process of RCA begins with the problem statement: What happened? Why is it a non-conformity? How is it outside the quality system requirements? This is done using a technique of continually asking “Why?” until the root cause is identified.³ Once identified, the chain of events leading to the root cause of the non-conformity is characterized as simple, complicated, or complex; a root cause may be characterized as chaotic, but this is rarely the case.⁴ The characterization will indicate the kinds of changes that need to be made to test if the identified root cause is the actual source of the non-conformity; additional observations may be needed to confirm this decision. The confirmed changes are then made to the root cause, taking the rest of the quality system into account, to see if the non-conformity is prevented from recurring. Periodic checks are made to provide feedback on the continual prevention of the non-conformity; that is, are the changes still preventing the non-conformity?

The RCA process is intended to be followed step by step; however, it may be necessary to revisit or repeat a step if something does not produce the expected results: (1) state the problem; (2) get to the root cause — the 5 “whys”; (3) the decision framework — simple, complicated, complex, or chaotic; (4) remediation; (5) feedback; (6) resume the process; and, (7) check for recurrence.

For example, if the problem statement is, “The analysis of a sample/specimen was not completed by the deadline,” then the root cause is determined by asking: (1) Why? The instrument failed to complete the run; (2) Why? The instrument ran out of carrier gas; (3) Why? The tank of carrier gas emptied mid-run; (4) Why? More gas was not ordered; and, (5) Why? An employee forgot to order more gas.

The “whys” provide a problem analysis (the problem has already been *stated*), a breakdown of effects and causes leading from the problem to the root cause. The remediation may be that a reminder is set in a calendar function to inform an employee when more gas needs to be ordered; the message is the feedback on the remediation. Testing can now resume with occasional checks for recurrence; that is, other samples not being completed by the deadline because of lack of carrier gases.

Thinking that only one cause exists is dangerous: *A cause never stands alone*. A good RCA will explore the causal chain thoroughly; other instances of the event may have occurred and the root cause may be more widespread and disruptive than initially assumed.

F19 **LEGLER: LEGal Linguistic Evidence Rulings and Forensic Linguistic Evidence**

*Carole E. Chaski, PhD**, ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947; *Harry L. Miles, JD**, Green, Miles, Lipton, & Fitz-Gibbon, LLP, 77 Pleasant Street, PO Box 210, Northampton, MA 01061-0210; *Aaron Alva*, 2001 E Yesler Way, #33, Seattle, WA 98122; and *Alexis I. Raykhel, MA*, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947

After attending this presentation, attendees will better understand the current and historical state of rulings concerning linguistic evidence in American jurisprudence. Attendees will learn how these rulings fit into the “four corners of forensic linguistics” and where litigation-independent research is needed, based on the judicial record of admissible or inadmissible methods.

This presentation will impact the forensic science community by helping attendees learn to accurately understand legal rulings about the current admissibility of different methods in forensic linguistics and to access a toolkit for evaluation of cases and rulings in forensic linguistics.

Whenever an attorney hires a forensic expert, he/she enters into a potentially unfamiliar area of science. This unfamiliarity is intensified when the forensic expertise involves an academic discipline that rarely appears in court. Linguistics is a rather rare academic discipline, with many universities offering only a course or two related to a major in foreign languages or education. Unsurprisingly, most attorneys have never heard of “forensic linguistics” or “linguistic evidence.” Further, most attorneys need help in evaluating the “forensic linguistics” or “linguistic evidence” that is being offered in a case because most attorneys are not linguists who are professionally trained in the academic discipline. Yet American courts have been considering and making rulings about the admission of linguistic evidence for more than 100 years and recently several high-profile cases have attracted attention to the idea of language as evidence. The 2014 ruling about the “Redskins[®]” trademark mentioned linguists hired by both sides to opine about the semantics of “redskins.” The 2012/2013 *Paul Ceglia v. Mark Zuckerberg* case highlighted language-based methodologies for determining authorship of electronic documents. On the pseudonymous landscape of the internet, forensic linguistic evidence will play an increasingly important role in investigation and litigation. The LEGal Linguistic Evidence Rulings (LEGLER) project helps attorneys quickly access rulings about forensic linguistic evidence and provides expert evaluations of the rulings from both the legal and linguistic perspectives.

LEGLER is web-accessible software that contains published rulings from American jurisprudence starting in the 1800s and continuing to the current year. Rulings were first gathered by an experienced attorney using one of the available legal databases. The 300+ rulings were then “scrubbed” by a computational linguist who wrote software to remove any proprietary information from the legal database. The scrubbed rulings were then loaded into the LEGLER section of ILER, a database platform for conducting web-based experimental research in forensic linguistics.^{1,2} Research associates of the Institute for Linguistic Evidence and subscribers to ILER can access LEGLER through a web-browser, with password authentication for the user account. LEGLER offers information beyond the legal databases (i.e., annotations by at least one attorney and at least one linguist). These annotations help the user organize and evaluate the rulings.

LEGLER annotations include several features: (1) each ruling is categorized as being from one or more of the “four corners of linguistic evidence,” (i.e., identification, text-typing, intertextuality, and linguistic profiling); (2) within the general category, each ruling is subcategorized by a specific topic. For instance, identification includes speaker, author, and language identification, or text-typing includes authentication of a document as a real suicide note, real threat, ransom note, and so forth; (3) each expert in the case is listed; and, (4) the method used by the expert(s) is evaluated for its relationship to linguistics. Methods related to linguistic evidence may be rooted in linguistics or other approaches to language such as literary criticism, prescriptive grammar, or computational stylometry. Only a trained linguist can accurately evaluate whether a method is rooted in linguistics or not, just as only an attorney can accurately evaluate the legal implications of a ruling. LEGLER annotations provide an interdisciplinary perspective on a ruling, search and organize rulings by all the usual legal parameters as well as linguistic methodology, and thus prepare for a case involving linguistic evidence with insight from both the law and linguistics.

F20 Trust — But Verify: The Reliability of Radiograph Techniques in the Courtroom

Jeffrey M. Jentzen, MD, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109*

After attending this presentation, attendees will understand some of the limitations of conventional radiographic techniques and the need for confirmation by another radiographic technique and/or pathological examination and interpretation by trained experts in the field.

The presentation will impact the forensic science community by illustrating the need for pathological documentation of radiographic findings for courtroom testimony and for insisting on a multidisciplinary approach to injury interpretation.

The routine use of radiographic imaging in forensic medicine and its presentation in the courtroom is constantly increasing. Radiographic documentation of injuries in child abuse and gunshot wounds, for example, has become standard practice.¹ Proponents of the routine use of radiographic imaging have argued that its use could eventually replace standard autopsy examinations. Recent studies have questioned the reliability of radiographic imaging and interpretation in the medicolegal environment. Molina et al. have demonstrated that Computed Tomography (CT) scans have a low rate of accuracy and sensitivity to provide definitive diagnosis and description of injuries at a legal standard for the courtroom.² This presentation will discuss representative cases where radiographic and clinical interpretation of injuries were overturned by the autopsy findings.

Case One: A 19-year-old male, distraught over the break-up from his girlfriend, sustained a self-inflicted gunshot wound to the head. The patient received CT imaging on admission to the hospital and was removed from life support five days following admission. The family was opposed to autopsy and a limited examination was performed. The CT report opined that the entrance wound was located on the left temple. The examination documented the entrance wound on the right temple.

Case Two: A 4-month-old infant sustained a traumatic head injury with skull fracture. In court, the radiologist was unable to opine whether or not the fracture had crossed the suture line. The autopsy convincingly demonstrated the extension of the fracture in the suture with extension. The finding had significant medicolegal importance on the amount of force and mechanism of injury sustained by the infant.

Case Three: A 3-month-old infant had been hospitalized since birth for congenital heart problems, had been recently discharged, and had gone home. The infant was examined in the emergency room after being found dead. The radiologist and Emergency Room (ER) physician diagnosed an “acute, comminuted depressed fracture to the occipital skull.” A subsequent autopsy revealed overlapping of sutures due to chronic compression of the skull.

Case Four: A 5-month-old infant was found dead. Pre-autopsy radiographs and CT scan failed to identify any fractures. An autopsy confirmed the presence of abdominal trauma as well as a recent fracture of the inferior occipital skull.

Case Five: A 35-year-old male sustained a gunshot wound to the head during an altercation. He remained in a coma and died three weeks later. On receipt of the autopsy report, the prosecutor questioned the identification of entrance and exit wounds because they were “not consistent with the ER physician statement.” Upon further review, despite CT scans and radiographs, the ER physician had misinterpreted the wounds.

Radiographic identification and documentation provides an important adjunct to the forensic autopsy. The low sensitivity, reliability of interpretation, and radiographic resolution of injuries requires pathological confirmation to attain the legal standards. The traditional autopsy remains the gold standard for the identification and documentation of injuries. The admission of a single piece of radiographic evidence in the courtroom should be confirmed by another method. Radiographic evidence submitted in the courtroom should be interpreted by trained experts in the field.

F21 Is the Medical Examiner's or Coroner's Official Cause of Death the Last Word?

Glenn G. Hardin, MPH*, Hamline University, MB 239, 1536 Hewitt Avenue, Saint Paul, MN 55116

After attending this presentation, attendees will understand the importance of an effective evaluation of the circumstances surrounding a questioned death and the findings at autopsy.

This presentation will impact the forensic science community by describing four cases in which review of the evidence regarding questioned deaths — medical records, witness statements, the results of external and internal examinations at autopsy, and postmortem toxicology analyses — either supported or refuted the medical examiner's or coroner's official Cause Of Death (COD).

Case 1: Involved a subject who died while lying prone with a police officer's knee placed on his back. The Medical Examiner (ME) determined that the COD was cardiopulmonary arrest and mechanical asphyxia, and the manner of death was homicide although the toxicology findings included dextromethorphan at 2.0mg/L in blood. The decedent's heirs sued the city for wrongful death. The city attorney hired an ME from another state who opined that the subject died from respiratory arrest due to dextromethorphan toxicity, even though in the months prior to this event, the subject survived being admitted to various emergency departments after ingesting 30 tablets of a dextromethorphan over-the-counter preparation. A major weakness in the city's case was that the police officer's partner recorded the death event with his cellphone.

Case 2: Involved a subject who died one morning after injecting himself with heroin the evening before and ingesting methamphetamine the day before. At autopsy, signs of respiratory depression and arrest were present that are associated with death due to morphine (heroin) toxicity, including pulmonary edema in both lungs, lungs weighing >500g, and pulmonary vasculature congestion. Additionally, there were no signs of cardiovascular issues. Before the toxicology results were reported, a suspect — a methamphetamine dealer — was identified. The heroin dealer was never discovered. The toxicology results revealed methamphetamine at 0.70mg/L, amphetamine at 0.16mg/L, and free morphine at 0.05mg/L in the blood. The coroner opined that the COD was methamphetamine overdose. The suspect was then charged with murder for providing the lethal dose. Prior to trial, the coroner's COD opinion was challenged by a medical examiner and a toxicologist. On the very eve of trial, charges were dismissed.

Case 3: Involved a subject who was admitted into the hospital one evening with severe back pain. Multiple Central Nervous System (CNS) depressant medications were administered, including morphine, cyclobenzaprine, hydromorphone, lorazepam, and tizanidine. The next day, the patient appeared to be tolerating the drug regimen; however, the following morning he was found dead with a mouthful of emesis. Autopsy indicated bilateral congestive pulmonary edema, right lung weight of 1,050 grams, left lung weight of 980 grams, and a bladder filled with urine. Toxicology results revealed a free morphine level of 0.16mg/L and cyclobenzaprine level of 0.02mg/L in blood. The coroner ruled the COD was morphine toxicity and the heirs sued for wrongful death. The hospital disputed the coroner's finding, arguing that the medical personnel administered therapeutic doses of the medications.

Case 4: Involved a subject who suffered a serious injury at work, for which he was prescribed oxycodone. For at least six months, he abused prescriptions for oxycodone, during which time he demonstrated tolerance to the increased doses by engaging in a variety of normal activities. One morning he was found dead in bed. Autopsy showed that the right lung weighed 495 grams and the left lung weighed 465 grams. The upper airways were clear of debris and foreign material with normal-appearing mucosal surfaces. The urinary bladder contained 50 cubic centimeters of urine. The heart weighed 500 grams. There was 90% of focal non-calcified narrowing of the proximal left anterior descending coronary artery and 80% narrowing of the first and second diagonal coronary artery. The blood oxycodone level was 0.66mg/L. The ME initially concluded that the COD was atherosclerotic cardiovascular disease; however, after a visit from one of the heirs, the ME two months later changed the COD to oxycodone toxicity.

Cause of Death, Forensic Toxicology, Evidence Evaluation

Jurisprudence Section - 2015

F22 Forensic Field Testing: Curse or Cure?

Vincent J. Desiderio, Jr., MS, 33 Potterfield Drive, Lovettsville, VA 20180*

After attending this presentation, attendees will be aware of both the value and potential pitfalls of field tests in the forensic context.

This presentation will impact the forensic science community by bringing to the surface the various potential issues involved with forensic field tests.

Field testing of evidentiary materials is not a new concept. From the beginning stages of the first scientifically driven examinations, investigators have sought methods to rapidly and reliably extract information from materials encountered in the field. For the most part, such testing has been regarded as presumptive in nature and generally required confirmation through more elaborate laboratory testing in a controlled environment.

Examples of such testing has included simple oxidative tests for the presumptive indication of blood (e.g., o-tolidine, Kastle-Meyer, luminol, etc.), wet chemical field test kits for the presumptive indication of controlled substances, and canine detection of ignitable liquid residues. Technological and engineering advances have now enabled the miniaturization of powerful instrumental analysis techniques to the point that it is possible to carry such instruments to a scene with little effort.

At this point in time, there are various manufacturers of field-portable Fourier Transform Infrared (FTIR) spectrometers, Raman spectrometers, and gas chromatographs with various detectors including mass spectrometers. Such instruments are often equipped with extensive data libraries that provide a best hit to the operator. In the not-too-distant past, the only place that such instrumentation with their accompanying libraries could be found was in an analytical laboratory where they were operated, for the most part, by individuals with in-depth scientific backgrounds under stringent operating protocols.

As these instruments have become smaller and easier to produce, their price points have dropped accordingly. It is now economically feasible for both large and small well-funded law enforcement and first responder entities to purchase and distribute such instrumentation for use. When combined with delays in laboratory analysis due to backlogs, it should be no surprise that there is a growing push to place such powerful instrumentation into the hands of the masses.

Although issues with the various forms of field tests are not new (there are still many issues with the older forms of field testing), the deployment of such powerful technologies appears to be outpacing the ability of the field to fully evaluate the impact that such technology might have. This should be a concern that raises several issues/questions including: (1) the fact that conflicts which have arisen in the past with the older technologies have not yet been fully addressed; (2) are the people that will be using such instrumentation qualified to make conclusions based on the findings they are receiving; and, (3) are any quality measures comparable to those expected in the laboratory being employed to validate and ensure proper operation at the point of use?

This presentation will discuss the various merits and potential pitfalls of the different techniques available for use in the field from a historical perspective. Parallels will be drawn between the measures that are taken in the laboratory compared to those that should be taken in the field. Although this presentation may lean toward a cautious approach for the implementation of these newer technologies, the primary purpose is to create awareness of some of the pros and cons of these approaches. In order to illustrate some of the points that are discussed, specific examples from both the literature and from real-life experience will be presented.

Field Tests, Chemical Tests, Field Portable Instrumentation

Jurisprudence Section - 2015

F23 Technical Investigations Not Repeatable in the Italian Code of Criminal Procedure: The Guaranteed Anticipated Contradictory of the Defense

Vincenzo Maria Bafundi, JD, Procura della Repubblica di Foggia, Viale I Maggio, Foggia 71122, ITALY; and Michele Vaira, JD, V. le I Maggio 27, Foggia 71122, ITALY*

After attending this presentation, attendees will understand that the Italian rules governing the activities of technical investigations about people, things, or places are subject to rapid change. In these cases, during the preliminary investigation conducted by the Public Ministry and carried out by the judicial police, the Italian Code of Criminal Procedure provides for the participation of other parties to the proceedings with the help of a consultant in order to establish a contradictory with the prosecutor.

This presentation will impact the forensic science community by underlining the usefulness of the presence and participation of legal experts appointed by the crime victim and the suspect to a plea that cannot be presented at trial. In this way, the private parties can contribute their own remarks to the technical investigation, rather than contend with the conclusions of the district attorney's consultant.

Italian rules of technical investigations not repeatable. When the investigations relate to people, things, or places whose state is subject to modification, the prosecutor immediately warns the defendant, the victim of the crime, and the defense of the appointed day, time, and place and of their right to appoint technical advisors. The defense as well as the appointed technical consultants shall be entitled to attend the meeting, to participate in the investigations, and to make comments and reservations. If, before the meeting, the defendant initiates an evidentiary hearing before the judge, the prosecutor cannot proceed unless these investigations, if delayed, may not be more usefully made. If the prosecutor, despite the express request of the defendant and not under the condition of urgency, has also carried out an investigation, these results cannot be used in the trial.

The classic example of non-repeatable technical assessment is the autopsy of a corpse or, in cases of murder or involuntary manslaughter (e.g., medical malpractice, car accident, or a work-related accident).

In cases of murder, rarely is there already a suspect; however, in those rare cases (e.g., murder committed within a family), the suspect may participate in a fundamental investigation, offering comments and reservations, and perhaps stating his defense, such as self-defense. In wrongful death cases, the suspect is generally known (e.g., the responsible physician, the driver of the car, or an employer). In these cases, experts appointed by the suspect can directly verify the correctness of the expert opinions, contributing to the investigation of the relevant facts (e.g., cause of death, relationship of cause and effect, and/or other contributing factors).

Technical Investigations, Anticipated Contradictory, Italian Criminal Procedure

F24 Communicating Error and Uncertainty in the Courtroom: The Language, Methods, and Psychology of Doubt and Belief

Ted W. Vosk, JD, 4040 Lake Washington Boulevard, NE, Ste 300, Kirkland, WA 98033*

After attending this presentation, practitioners will have a better understanding of: (1) how to effectively communicate forensic results and their uncertainty to fact-finders; (2) the psychological and cognitive dynamics created by the presence of error and uncertainty which may hinder rational decision making; (3) how these forces interact with the formation of belief or doubt in arriving at verdicts; and, (4) the creative use of language and analogies in educating fact-finders.

This presentation will impact the forensic science community by facilitating communication of forensic results in a manner intended to lead to legal outcomes that are consistent with scientific reality. Attendees will be provided tools for clearly illustrating what a scientific result represents, the role played by its uncertainty, and the limitations the uncertainty places on the conclusions supported by a result. These tools help dispel naïve notions of “scientific certitude” and facilitate informed, unbiased consideration of forensic results and the verdicts they support.

Scientific results do not permit us to know anything with absolute precision. Rather, due to the presence of error and necessarily imperfect and incomplete information, the conclusions supported by forensic results are always accompanied by uncertainty. A consequence of this is that forensic science cannot establish what is or is not true, but, rather, only what is more or less likely based upon the information possessed. Thus, relatively justified belief concerning a physical state rather than knowledge of the actual physical state itself is what science leads to. This holds for all fields of science and any results obtained no matter how good the procedures, equipment, or scientists involved. Only by properly understanding what conclusions scientific results actually support can fact-finders issue verdicts that consistently comport with the science underlying the result relied upon. As a result’s uncertainty conveys the conclusions the result supports, a critical aspect of the decision-making process is an adequate understanding of a result’s uncertainty and what it represents.

Unfortunately, many triers of fact don’t realize that uncertainty is a part of all forensic results and instead imbue them with an “aura of scientific infallibility,” interpreting them as a direct revelation of the truth of what is to be proved. This misunderstanding of what these results represent undermines the fact-finding process leading to legal outcomes that must be questioned even when the science relied upon is sound. Knowing the problem doesn’t solve it, though. Conveying these concepts so that they can be understood in the context of a trial or hearing by scientifically naïve decision makers can be difficult. Moreover, awareness of the existence of uncertainty itself creates psychological and cognitive impediments to rational decision making which creates further complications. The reaction of some to the presence of uncertainty is to reject a proposition altogether regardless of how certain it is. The reaction of others is to reject uncertainty altogether regardless of how uncertain the proposition is. Neither response is warranted in most contexts.

If the ultimate mission of our courts is the determination of factual truth, fact-finders must be taught to appreciate the role played by scientific uncertainty and to weigh scientific evidence in a rational manner consistent with science itself. In the courtroom, the responsibility for communicating what forensic results represent and the conclusions they support rests with scientific witnesses testifying about the results and the legal professionals presenting or challenging them. If forensic results are to be considered and weighed in a scientifically defensible manner by fact-finders, then these forensic and legal professionals must be able to act in the capacity of courtroom teachers, educating decision makers so that they are equipped to make informed decisions. This involves creative use of both language and analogies, translating scientific jargon and concepts into laymen’s terms and images. When used effectively, these tools not only facilitate understanding but diminish the impact of psychological and cognitive blocks to rationality.

This presentation will address the challenge of communicating scientific results and their associated uncertainty and will present tools that can be used to facilitate this process in a manner that both educates substantively as well as defusing psychological and cognitive blocks to rational decision making.

Uncertainty, Error, Communication

F25 Errors in DNA Testing: Lessons Learned — A Retrospective Look

Charlotte J. Word, PhD, PO Box 5207, Gaithersburg, MD 20882*

After attending this presentation, attendees will understand: (1) some of the limitations of DNA testing; (2) what types of errors may occur during DNA testing; (3) more about the detection, prevention, and remediation of errors in DNA testing; and, (4) current issues in testing and interpretation of DNA samples with small amounts of DNA and/or mixtures of DNA from three or more contributors.

This presentation will impact the forensic science community by providing information regarding the types of errors that may be encountered in forensic DNA testing, some of which could lead to misinterpretations of the data with false inclusions or false exclusions of known individuals.

There are errors inherent to all test systems and DNA testing is no exception. Since its introduction to the forensic science community almost 30 years ago, a great deal has been learned about the limitations and errors of DNA testing. It is true that there is a minimal chance of errors in testing and interpretation if evidence collection and handling are correctly performed, properly validated laboratory procedures are duly followed with appropriate controls being used and monitored, and analysts are well trained in the technical procedures and in the interpretation and reporting of the data. The types of errors that can occur in DNA testing, including human errors and errors related to limitations of the technology, will be discussed. Information regarding which type of errors may be detected and how they may be identified will be provided. Possible preventative steps and remediation activities will also be presented.

Examples of current problems in DNA testing of biological samples resulting from the dramatic influx of evidence items seized from property crime scenes will be provided. Stochastic effects that commonly occur when polymerase chain reaction technology is used for the amplification of small amounts of DNA, termed low template DNA, can result in DNA profiles that are not reproducible and do not reflect the DNA profile of the true contributor of the DNA sample. Many of these samples are complex mixtures of DNA from three or more contributors, some of whom may be related. Testing and interpretation issues resulting from these types of samples will be discussed, including the possibility of the reporting of false inclusions and exclusions of individuals and the difficulty in providing reasonable statistical frequency estimates.

It is important for the forensic science community to recognize and acknowledge the types of errors that can occur during testing. It is critical that a culture is developed and promoted where the detection and correction of mistakes is strongly encouraged and perhaps even rewarded. Laboratory management and analysts should be forthcoming regarding any errors made and any limitations to a test system to prevent a miscarriage of justice. The identification and acknowledgement of mistakes and errors provide a noteworthy opportunity for additional corrective training and for the introduction of preventative measures and improved procedures aimed at generating the best, most reliable, and defensible testing results possible.

Errors, DNA, False Results

F26 Culture of Infallibility: The Inability of the Criminal Justice System to Concede Scientific Uncertainty

Roderick T. Kennedy, JD, New Mexico Court of Appeals, PO Box 25306, Albuquerque, NM 87125-0306*

The goal of this presentation is to discuss new research which demonstrates how the investigative process by which cases come to court is frequently comprised of a mix of good and bad evidence that the judicial system cannot always adequately evaluate.

This presentation will impact the forensic science community by explaining how it is necessary to understand the adversary process by which the judicial system resolves claims and the effects this process has on the quality of evidence both as presented and as understood. The cooperation of all stakeholders — law enforcement, attorneys, forensic scientists, and judges — to understand the need to reform the practices of each must underlie true reform.

Social and behavioral scientific research demonstrates that bias infects the criminal justice system; forensic science, police departments, prosecutors, the criminal defense bar, and even the judiciary. It is directly related to unsafe judicial results and wrongful convictions. The revealing of motivational, relational, and confirmation bias that can affect forensic testing has incited obloquy from the forensic science community against anyone speaking of it, but that is far from the whole story. The conformational bias (tunnel vision) that can lead police investigators to pursue only the evidence most consistent with their pre-existing theory while rejecting confounding facts similarly leads to prosecutors failing to consider other possibilities (assuming a complete set of facts is even available). Similarly, prosecutors considered that their need for absolute guilt made any uncertainty in evidence, even what might be subject to ready explanation, intolerable as somehow indicative of reasonable doubt. Defense attorneys, accustomed to slam-dunk cases being brought against their clients, have learned not to seriously question forensic evidence, the reliability of which judges say can be “taken for granted” because they have been used for decades. The process by which evidence is evaluated to determine criminal liability is demonstrably unstable when the discernment of truth and falsehood are often most critical. Despite knowing about solvable problems, change is resisted.

Years ago, as prosecutors began to have confidence in the seeming certainty of forensic science, evidence technicians were trained to use phrases like “absolute certainty,” “100% accurate,” and “to the exclusion of every (fill in item) in the world.” Eyewitnesses were considered the “gold standard” of criminal trial evidence, particularly when they were victims. Driving while intoxicated/impaired cases, tried on the basis of “under the influence,” became inconvenient because of a flexible relationship between alcohol levels and impairment, necessitating the adoption of a “science-based” per se offense based on a number—the blood alcohol concentration. A mythological impression of infallibility accompanied the forensic expert to court, where prosecutors neglected to understand the evidence they presented, defense attorneys missed opportunities to question what might be questionable, and judges were happy with quick-moving cases that conformed to what were often their own preconceptions of the evidence. The adversary system masked what needed to be an open-ended search for the best evidence for the case.

Then came DNA. With its arrival, two important things were discovered: (1) what it looked like when laboratory-validated molecular science was practiced to rigorous standards and applied with equal statistical rigor to predict probable outcomes; and, (2) that in the face of irrefutably unique chemical bonding, when this new scientific evidence was used in old cases, it exposed the wrongful convictions of innocent persons. Since forensic evidence is a creation of the law, used by the law, and has little application outside the law, the fact that it had been used in so many cases proven to result in wrong outcomes began to draw scrutiny and the result of the scrutiny was not always favorable. There being no “tolerable” number of wrongful convictions, the traditions embodied in the law and its use of evidence in criminal cases, required reassessment. Inertial resistance to change, a “chicken little” attitude within forensic science, and a lack of widely-accepted standards for forensic science work and the way its results were expressed in court were all exposed as impediments to progress.

Recent books point to the influence of a great number of failings in the criminal justice system, many of which are so inherent to various police, forensic, and legal practices that they have escaped evaluation. Exposure breeds resistance by these actors. The need for the infallibility of the court system and proof beyond a reasonable doubt have created a culture that supports uncritical myths of infallibility. Resistance to change does not reward team playing, consistency of opinion, and critical thinking.

Jurisprudence Section - 2015

This presentation will discuss the directions in which legal scholarship is attempting to identify and correct many of these quite unintentional sources of error in judicial determinations. A message is that the overarching quest for justice is best served by cooperation and greater examination of best practices to avoid exonerating the guilty and convicting the innocent.

Change, Resistance, Judicial System

F27 To Err or Not to Err: How Judges and Jurors Apply “Margin of Error” and “Coefficient of Variation” to Their Determinations of Blood Alcohol Content in Criminal Cases Involving Blood Testing

Stephanie Domitrovich, JD, PhD, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501*

After attending this presentation, attendees will better understand the legal requirements of “margin of error” and “coefficient of variation” as applied in the courtroom.

This presentation will impact the forensic science community by providing the bases for “margin of error” and “coefficient of variation” as applied in the law.

In federal courts, federal trial judges apply the Daubert standard to make the preliminary assessment of whether an expert’s scientific testimony is based on methodology that is scientifically reliable and can be properly applied to the facts at issue. In state court jurisdictions, state trial jurisdictions vary on the application of which standard that state court applies for admitting scientific evidence: Daubert, Frye, or a combination of both standards, now coined as Fryebert, states the trial judge may apply each standard separately to the same factual methodology so that two analyses are conducted to cover both bases of Frye and Daubert standards.

When state trial judges apply the Frye standard to determine the admissibility of scientific evidence, the scientific theory must be “generally accepted” in the relevant scientific community. The Daubert standard allows trial judges to evaluate novel scientific evidence using a variety of factors in determining whether the expert’s methodology is valid, such as, but are not limited to, the following: (1) whether the theory or technique in question can be and has been tested; (2) whether the theory or technique has been subjected to peer review and publication; (3) what is the theory’s known or potential error rate; (4) whether there is existence and maintenance of standards controlling its operation; and, (5) whether the theory has attracted widespread acceptance within a relevant scientific community.

This presentation will discuss how “margin of error” and “coefficient of variation” as scientific and legal concepts are viewed by state trial judges, appellate court judges, and juries as reflected in their decisions regarding blood alcohol content in blood tests in criminal cases in a Frye jurisdiction such as Pennsylvania. How are these scientific and legal concepts viewed by these judges and juries in a Frye jurisdiction such as Pennsylvania where scientific methodology need only be “generally accepted” in the relevant field of science? In a Frye jurisdiction, is it an abuse of discretion for a state trial judge to view “margin of error” evidence or “coefficient of variation” evidence in a light most favorable to the commonwealth when the judge considers a challenge to the weight of the evidence? Is the jury “speculating” or trusting that the defendant’s actual blood content was .16% or higher within two hours when no direct or circumstantial evidence is presented to the jury at the time of trial regarding the possible source or basis for the application of a 10% “margin of error?” In a Frye jurisdiction, should the laboratory tests be considered scientifically valid when the testing is done by an approved testing facility in accordance with established “generally acceptable procedures” when the laboratory tests uses only one sample of blood? A judge will grant a new trial based on the weight of the evidence claim in cases where the factfinder’s verdict is “so contrary to the evidence that it shocks one’s sense of justice.” Should there be a grant for a new trial if the jury is not informed of the application of the 10% margin of error in the actual alcohol blood testing result? Does that verdict “shock one’s sense of justice?”

Margin of Error, Frye Jurisdiction, Scientifically Valid

F28 Lost and Gone Forever — Jeopardized Prosecutions and Denial of Due Process

Peter R. De Forest, DCrim, PO Box 141, Ardsley, NY 10502; James M. Doyle, LLM, Bassil, Klovee & Budreau, 20 Park Plaza, Ste 1005, Boston, MA 02116; Gregory B. Matheson, BS, Los Angeles Police Department, Crime Laboratory, 1800 Paseo Rancho Castilla, Los Angeles, CA 90032; Rebecca E. Bucht, PhD, Pietarinkatu 11 A 13, Helsinki 00140, FINLAND; and John J. Lentini, BA, Scientific Fire Analysis, LLC, 88005 Overseas Highway, #10-134, Islamorada, FL 33036*

The goal of this presentation is to make attendees aware of the importance of early scientific involvement at crime scenes.

This presentation will impact the forensic science community by pointing out the value of having experienced scientists (criminalists) involved in crime scene investigations from the outset.

Events leave physical traces which form a physical evidence record of the event. Humans may be concerned about such physical evidence records extending over extremely vast timescales. Depending on the time frame, some past events may be the subject of investigations by cosmologists, astrophysicists, geophysicists, geologists, paleontologists, or archaeologists. The record is created by processes that are subject to physical laws. Cleland has characterized these investigative endeavors as “historical science.”¹ All are centered on developing a scientific understanding of the physical evidence record. Myriad physical evidence records are being created continuously. Some are the result of human activity. The vast majority of more recent events may be inconsequential; however, some small fraction of much more recent events can be of great concern in accident or criminal investigations.

To some extent, this record is written over the records of preceding events at the same location. In addition, this record will be overwritten by the record resulting from events that follow. This statement has important implications. A crime scene may contain hundreds, if not thousands, of items. Many of the most relevant and significant items will not be obvious. How can the remnants of antecedent events be accounted for and separated from the traces of the event of interest? What can be done to minimize the addition of traces from post-event activities?

Most well-read laypersons would be appalled to see reports of non-scientifically trained persons excavating some site of a past civilization with a power-driven excavator and loading the excavated material into barrels for shipment to an archaeologist at some university or other research center. Why doesn't the same concern seem to extend to the practice of the collection of evidence by non-scientist police officers at crime scenes?

Lay critics of crime scene work in specific cases tend to think in terms of errors or omissions made at the crime scene. This is overly simplistic conceptualization. Every crime scene is different. Each presents challenging scientific problems. Unfortunately, most crime scenes are not the subject of a scientific investigation. Most are treated with a “bag-and-tag” mentality. Evidence that is not recognized at a crime scene is lost and gone forever. This loss may allow the guilty party to go free or it may have been something that provided evidence that would have been effective in clearing an innocent person who is subsequently accused. In most jurisdictions internationally, law enforcement has the responsibility of the crime scene investigation. What are the implications for the defense in a criminal case? What rights does the defendant have? What control can the defendant have over the crime scene examination and investigation? In present practice, none at all. Can a defendant be irreparably harmed by the premature release of a crime scene? What remedies exist or can be envisioned?

F29 Legal Update: Recent Court Decisions Declaring Testimony About Case Reviews Performed by Non-Testifying Experts to Be Inadmissible

Andrew Sulner, MSFS, JD, Forensic Document Examinations, LLC, 220 E 57th Street, Ste 200, New York, NY 10022*

After attending this presentation, attendees will be better informed about some recent court decisions and the evidentiary grounds that have led courts to declare that expert testimony about case reviews performed by non-testifying experts is inadmissible.

This presentation will impact the forensic science community by educating all stakeholders in the administration of criminal or civil justice — experts, lawyers, and judges — about the evidentiary issues that preclude expert testimony about casework peer reviews by non-testifying experts.

Expert witnesses from various forensic disciplines have often testified that their casework is subjected to so-called “peer review.” Such testimony, generally elicited during direct examination, is supposedly introduced for the purpose of demonstrating the quality assurance protocol employed in the testifying witness’ forensic laboratory prior to the issuance of a final report. Lawyers and trial judges frequently assume that the mere mention of the words “peer review” equates to a comprehensive reexamination of the evidence and an independent verification of a given opinion or conclusion; however, sometimes the so-called “peer review” comprises little more than a “spell check.”

Some lawyers have attempted to challenge such testimony by establishing that the casework peer review was biased and unreliable because it was not performed blindly, e.g., the reviewer was a “friendly” colleague or coworker, working in the very same laboratory unit or office; however, as some recent court decisions indicate, testimony about case reviews performed by non-testifying experts has been ruled inadmissible on evidentiary grounds, and lawyers, judges, and testifying experts need to know the impact of these recent court rulings.

Casework Reviews, Inadmissible Testimony, Bolstering

F30 Reliability, Validity, Accuracy, and Bias in Forensic Document Examination: Results From an Interdisciplinary Study of Questioned/Known Signature-Comparison Tasks

*Mara L. Merlino, PhD**, 1066 Tamworth Lane, Frankfort, KY 40601; *Tierra M. Freeman, PhD**, Kentucky State University, 229 Hathaway Hall, 400 E Main Street, Frankfort, KY 40601; *Veronica B. After attending this presentation, attendees will understand some of the theoretical principles of cognitive psychology and how the application of psychological principles and research methods to the question of how Forensic Document Examiners (FDEs) reach conclusions provided important information about some of the cognitive and physiological aspects of the evaluation of signatures. This presentation discusses some of the relationships among signature type, signature complexity, and the deployment of attention in signature comparison tasks as they relate to process and authorship decisions in a sample of handwriting comparisons.

This presentation will impact the forensic science community by demonstrating the importance of engaging in theoretically based, multidisciplinary research to reach an understanding of the nature of the methodology and expertise in forensic document examination.

This presentation reports findings from a national study of forensic document examiners concerning the deployment of visual attention as it relates to signature type and complexity.

A substantial portion of FDE training is devoted to signature comparisons, handwriting, and hand printing. FDEs seek those features and characteristics which may represent the document's identifying attributes. Examiners first determine the presence or absence of features, and then qualitatively assign these features some degree of evidentiary weight to reach their decisions. Examiners are trained to look for both substantial similarities and differences among writing samples and for repeated small characteristics which may sufficiently establish that writings are clearly the work of two individuals even though they may contain many general similarities. The number and quality of these features allow FDEs to make assertions about the authorship of the specimen and the extent of their confidence in their decisions.¹

Many current theories of attention propose that attention is based on the relationship between a bottom-up, saliency-based attentional system and a top-down, feature-specific selection mechanism. Attention is guided by relational information about the target or by information about how the irrelevant information of a non-target differs from the features of the target. Relational models of visual search demonstrate that visual attention can be guided by attending to specific feature values such as color, size, or intensity, by inhibiting attention to irrelevant features, or by directing attention to how stimuli differ. Relational models place the target in relation to its context, offering more specific (e.g., directional) information about differences.²

The features available for forensic evaluation are determined in part by the nature of the writing specimens. For example, compared to stylized or mixed signatures, text-based signatures may offer a greater variety of features for evaluation. Additionally, signatures vary in terms of their complexity (e.g., the number of turning points and crossing lines), their semantic content, and any number of additional features commonly recognized within the profession as indicators of the authenticity of the writing. Findings will be discussed in the context of Amos Tversky's "contrast model," which posits that most stimuli seem to be effectively described by the presence or absence of qualitative features. He and others argued that an object is represented by a set of features or attributes, and that judgments of similarity are achieved through a process of feature matching. The contrast model systematizes this "feature" approach and proposes that similarity depends on the proportion of features common to the two objects and also on their unique features.³

Signature Comparison, Interdisciplinary Research, Reliability and Validity

F31 Prosecutorial Misconduct and Breaches in the *Brady* Doctrine

David M. Benjamin, PhD*, 77 Florence Street, Ste 107N, Chestnut Hill, MA 02467-1918

The goals of this presentation are to review the *Brady* Doctrine and examine cases of prosecutorial misconduct and breaches in the *Brady* Doctrine that have resulted in due process violations.

This presentation will impact the forensic science community by raising awareness of how *Brady* Doctrine violations prevent citizens from obtaining their due process rights.

The Registry of Prosecutorial Misconduct defines prosecutorial misconduct as any conduct, intentional or inadvertent, during the course of prosecution that: (1) violates the applicable code of professional ethics; (2) breaks a pertinent law; or, (3) prejudices, or appears to prejudice, the administration of justice.¹

A major claim against prosecutors is violations of the *Brady* Doctrine.² In *Brady v. Maryland*, the Supreme Court held that “the suppression by the prosecution of evidence favorable to an accused upon request violates due process where the evidence is material, either to guilt or to punishment, irrespective of the good faith or bad faith of the prosecution.”³ Most disputes over *Brady* issues focus on the definition of what is “material.” Recently, the Supreme Court defined evidence as “material” when “there is a reasonable probability that, had the evidence been disclosed, the result of the proceeding would have been a different.”⁴ In toxicology cases, failure to produce an exculpatory lab test occurs and the ramifications of this will be discussed.

Moreover, there are a number of questions related to the prosecutor’s duty to disclose material exculpatory evidence that are still unresolved: (1) what is the depth of the duty *Brady* imposes on prosecutors to look for and turnover material exculpatory evidence; (2) do a district attorney, attorney general, and United States attorney all share the same duty under *Brady*; (3) if a prosecutor fails to meet the duty under *Brady*, is the director of that operation vicariously liable for the omissions of subordinates; (4) can a prior defendant who was prejudiced by that action sue for civil liability; and, (5) in the absence of the right to sue for civil liability, what other legal remedies does the defendant have to right a prior breach? Filing a petition for a new trial and alleging both fraud against the government and ineffective assistance of counsel who represented the defendant are common. Failure to discover the withheld documents is ineffective, and the government’s failure to conduct an adequate search for the material exculpatory information or produce it in a timely manner rendered the trial fundamentally flawed.

Connick, District Attorney, et al. v. Thompson addressed the issue of vicarious liability of local government agencies.⁵ In *Connick*, John Thompson was convicted of attempted armed robbery. The Orleans Parish District Attorney’s Office conceded that prosecutors failed to disclose evidence that should have been turned over to the defense under *Brady*. Thompson was convicted. Because of that conviction, Thompson elected not to testify in his own defense in his later trial for murder and he was again convicted. Thompson spent 18 years in prison, including 14 years on death row. One month before Thompson’s scheduled execution, his investigator discovered that evidence had been withheld in his armed robbery trial. The reviewing court determined that the evidence was exculpatory and both of Thompson’s convictions were vacated.

After his release from prison, Thompson sued the Orleans Parish District Attorney, Harry Connick, in his official capacity for damages, alleging that Connick had failed to train his prosecutors adequately about their duty to produce exculpatory evidence and that the lack of training had caused the failure to disclose in Thompson’s robbery case.⁶ The jury awarded Thompson fourteen million dollars and the Court of Appeals for the Fifth Circuit affirmed. The Supreme Court ruled that local government liability for failure to train cannot be based on a single incident, but the plaintiff must show a pattern of similar constitutional violations.

Commonwealth v. Christina Martin, a case where the prosecution failed to turnover a negative confirmatory gas chromatography/mass spectrometry test will be discussed, and the analysis of the motions judge shared.⁷

F32 Ethics in the Study of Forensic Science: Can Ethics Be Taught?

Linda L. Chezem, JD*, 530 Denny Drive, Mooresville, IN 46158

After attending this presentation, attendees will consider how the formal study of ethics might be evaluated to determine the impact on ethical responses of forensic science professionals.

This presentation will impact the forensic science community by delineating how increased attention will be given to the ethics being taught to future professionals in forensic sciences. Suggestions will be garnered to improve the teaching of ethics. An additional result is that consideration will be given by academics and professional societies to strengthening the ethical standards and improving adherence to those standards.

This session will present an updated survey of ethics hours offered by forensic science programs that are accredited by the Forensic Science Education Programs Accreditation Commission (FEPAC). The session will also review the learning objectives, the textbook, and other class materials for a three-hour semester credit class. The class, "Forensic Science Ethics," taught at Purdue University was created as the capstone class for the forensic science minor. The impetus to create the class arose from the expense and disruption caused by problems at the Indiana State Department of Toxicology. The fact that other laboratories were facing challenges at that time added weight to the decision. As the current requirements for ethics instruction were reviewed with colleagues, some skepticism was voiced as to whether ethics can be taught. This presentation's counter argument, silence equals complicity, will be discussed.

The question of how the class impact might be properly evaluated will also be discussed.

Ethics, Teaching, Forensic

Jurisprudence Section - 2015

F33 Shaken Baby Syndrome: Current Evidence of a Pathological Entity

Jeffrey M. Jentzen, MD, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109; and Carl J. Schmidt, MD, Wayne County MEO, 1300 Warren, Detroit, MI 48207*

After attending this presentation, attendees will recognize recent studies and publications on the proposed mechanism of sudden death associated with the Shaken Baby Syndrome (SBS). The presentation will discuss enhanced dissection techniques for the identification and documentation of neck injuries in suspicious infant deaths.

This presentation will impact the forensic science community by providing documentation of fatal neck injuries in infants suspected of abuse. It will provide insight into the injuries critical in explaining deaths due to SBS.

For the past 30 years, physicians have diagnosed SBS on the basis of the triad of subdural hematoma, retinal hemorrhages, and brain swelling. It is estimated that more than 1,000 infants are diagnosed with SBS in the United States each year. The entity was initially described by Caffey and others as unexplained subdural hemorrhage in infants without observable trauma or impact. Unable to demonstrate an acceptable mechanism of death in cases due to shaking, proponents have argued that the presence of associated trauma to the chest and ribs, lack of scalp impact, along with studies of post-conviction confessions supports shaking as a mechanism of injury.¹

Critics of the existence of SBS point to research using primates and inanimate models that show shaking alone provided insufficient biomechanical force to cause the formation of subdural hemorrhage as well as questioning the veracity of confessions. Defense experts routinely site incidental short-distance falls, resuscitation efforts, or rare medical problems as the cause of the subdural and retinal hemorrhage. Legal experts decry the lack of evidenced-based medicine and argue that until the mechanism of death in SBS is detected, it does not exist.

In 2008, the Wisconsin Court of Appeals supported a request for a new trial for Audrey Edmunds who had been convicted in the death of a 7-month-old child ten years earlier. During the testimony, the original pathologist volunteered that he could no longer support his prior testimony. Following the testimony of numerous experts, the court ruled for a new trial in that “a shift in mainstream medical opinion” had undermined the diagnosis of SBS.²

In 2011, Evan Matshes, a forensic pathologist, published a paper describing an enhanced dissection technique of the cervical spine of infants suspected of abuse. Using a matched control group, Matshes demonstrated the presence of hemorrhage in spinal nerve roots, especially in those responsible for respiration and heart rate. This study confirmed the findings of other forensic pathologists with similar cases. The findings of cervical spinal trauma is an acceptable mechanism to explain death in SBS.³

In addition to Matshes, forensic pathologists in the New York City Office of the Medical Examiner have confirmed other published studies, the presence of subdural hemorrhages, subarachnoid hemorrhage, and optic nerve hemorrhages and brain swelling without evidence of head impact after a thorough postmortem examination. In their study, 10/46 (22%) of infant homicide cases lacked an impact site. Of these, 29% demonstrated spinal nerve hemorrhage. It is argued that whiplash shaking without impact is the cause of death in a subset of infant homicides.⁴

In light of new techniques in the examination of an injured child, prosecutors, judges, and medical experts should evaluate all the existing evidence when deciding whether a child has been fatally shaken, especially when there is no other clinical context to explain what is otherwise a fatal head injury.

F34 Depraved Indifference — Murder of a Child in New York: Are Moms Getting Away With Murder?

Kerry J. O'Connell, JD, NY County District Attorney, One Hogan Place, New York, NY 10013*

After attending this presentation, attendees will wonder whether those who cause the death of innocent children are being held to a proper legal standard as, over the years, New York's appellate courts have restricted the application of "depraved mind" murder (an equivalent in seriousness to intentional murder) for prosecutors.

This presentation will impact the forensic science community by illustrating deficiencies or "quirks" in the law of child abuse that prevent parents from being held responsible for the deaths of their children in egregious, "non-intentional" cases if they have attempted assistance in any way.

In the presented case study, the evidence overwhelmingly established that the defendant knew her son had sustained devastating, life-threatening injuries at the hands of her domestic partner and was in severe pain. Nevertheless, she did not call an ambulance or take her son to the hospital. Instead, she and the codefendant made worthless and belated efforts to treat the child with home remedies and children's acetaminophen. The defendant otherwise ignored her child's injuries over a period of seven hours. During this time, the defendant made casual telephone calls without mentioning the child's injuries, drank beer, and smoked, and then went to sleep. She finally called 911 at or around the time the child died. Even then, she took the time to dispose of potentially incriminating evidence before making the call. Furthermore, she admitted that she did not seek medical attention earlier because she was afraid of being blamed for the injuries. The fact that she deliberately placed her own interests ahead of her son's need for emergency treatment was strong evidence that her omission evinced depraved indifference rather than mere recklessness or negligence.

The mother's conviction was upheld at the intermediate appellate level; however, the highest appellate court reversed and remanded, finding that the treatment, given after the injuries were obvious, was a quintessential case of far too little, far too late; but to them demonstrated that it did not support a finding that she did not care at all. As for the fact that she attempted to conceal the crime, that also did not, in the court's view, evince a mental state of depraved indifference. Zahira Matos pleaded guilty to a new indictment charging her with Reckless Manslaughter.

Lawyers may be surprised to learn that even a studied indifference to the duty of care owed to a child by his mother can be considered merely reckless in New York, even when horrific injuries are demonstrated, as long as they cared to the smallest extent — even if the child is left to die.

This presentation introduces a case study of a child severely beaten by his mother's domestic partner, and then left without medical treatment in full view of both as they labored to cover up their crime. Experts at the trial of the mother found that the child died from child abuse syndrome and suffered for hours before death. When the two women finally called for police and medical assistance, the child had likely been dead for hours.

Child Abuse, Wound Interpretation, Homicide

Jurisprudence Section - 2015

F35 Child Psychological Abuse: Legal and Clinical Implications

*Stephanie Domitrovich, JD, PhD**, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501; and *William Bernet, MD**, Vanderbilt University, 1313 21st Avenue, S, 209 Oxford House, Nashville, TN 37232

After attending this presentation, attendees will understand the definition of Child Psychological Abuse (CPA), clinical manifestations of CPA, legal implications of CPA, and criteria for reporting suspected CPA to child protection personnel. Attendees will also recognize how to distinguish parental estrangement (which typically involves physical abuse) from parental alienation (which involves CPA).

This presentation will impact the forensic science community by increasing the competence of mental health professionals in recognizing CPA in their clinical or forensic practice, thus helping them achieve greater confidence in treating and reporting CPA. Legal professionals will have increased competence in addressing CPA when it occurs in child custody cases and in dependency/neglect hearings.

Although the existence of child maltreatment can be traced to ancient times, it was not until the modern era that the mistreatment of children became a widely recognized social issue, which professionals in science and in law have addressed in order to protect children from harm. Psychologists, physicians, and social scientists have conducted research to analyze, identify, and understand this issue, while lawyers, judges, and social workers have been preparing directives and safety plans to protect children from maltreatment. The goals of science and law intersect to protect children from abuse.

Child maltreatment can be categorized into four types of abuse: (1) physical abuse such as kicking, biting, shaking, bruising, stabbing, or punching to cause physical injuries; (2) sexual abuse such as fondling, intercourse, exhibitionism, and commercial exploitation through prostitution and pornography; (3) neglect is the failure to meet children's basic needs for food, clothing, medical attention, or proper supervision; and, (4) emotional/psychological abuse such as social isolation, repeated unreasonable demands, ridicule, humiliation, intimidation, or terrorizing, which causes serious mental or behavioral disorders. Among these four types of abuse, the presenters will focus on the last form of child maltreatment — emotional/psychological abuse.

The federal definition of CPA refers to acts or omissions — other than physical abuse or sexual abuse — that caused or could have caused: conduct disorder, cognitive disorder, affective disorder, or other mental disorder. CPA frequently occurs as verbal abuse or excessive demands on a child's performance. CPA is a difficult topic for legal professionals and mental health practitioners to understand and address. The child protection agencies in the states have widely different approaches to identifying CPA; among the 50 states, the frequency of CPA ranges from 0.1% to 51% of substantiated cases of child maltreatment.

It is likely there will be an increased interest in this topic because CPA finally became an official diagnosis for mental health professionals in the United States when the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), was published in 2013. The presenters will explain: (1) a brief history of CPA from the 1970s to the present time; (2) various definitions of CPA; (3) federal and state legal cases in which CPA was an issue; (4) clinical manifestations of CPA; and, (5) guidelines for reporting suspected CPA to child protection personnel. Also, there will be a discussion of the importance of distinguishing parental estrangement (when a child refuses contact with a parent because of a history of physical abuse, sexual abuse, or neglect) and parental alienation (when a child refuses contact with a parent because the child has been indoctrinated to fear or hate the rejected parent, which is a form of CPA).

Child Psychological Abuse, Parental Estrangement, Parental Alienation

F36 Hoarding Disorder: Whose Problem Is It, Anyway?

James P. Cho, MD*, 238 County Down Lane, Loveland, OH 45140; and Scott Bresler, PhD*, UC Medical Center, Division of Forensic Psychiatry, 260 Stetson Street, Box 670559, Cincinnati, OH 45219

After attending this presentation, attendees will be able to: (1) specify the *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition (DSM-V) criteria of hoarding disorder; (2) describe the limited treatment options for hoarding disorder; (3) understand that mental health treatment for an involuntarily committed patient was ruled constitutional under the 14th Amendment by the United States Court of Appeals, Fifth Circuit; and, (4) identify that the issues of involuntarily committing and treating a person for hoarding disorder may be incompatible with attaining therapeutic benefit.

This presentation will impact the forensic science community by presenting several of the questions yet to be answered about hoarding disorder's place within the realm of involuntary commitment and court-ordered treatment.

Statement: Hoarding disorder is a new diagnosis in the DSM-V, but there are several questions yet to be answered about its place within the realm of involuntary commitment and court-ordered treatment.

Brief Synopsis: Hoarding disorder is a new diagnosis in the DSM-V that is generally understood to be potentially dangerous to one afflicted by it and perhaps to the community at large. The disorder presents with challenges to clinicians and the law as to where it fits within the context of involuntary commitment and treatment.

In the case of *Donaldson v. O'Connor*, the United States Court of Appeals stated, "We hold that a person involuntarily civilly committed to a state mental hospital has a constitutional right to receive such individual treatment as will give him a reasonable opportunity to be cured or to improve his mental condition."¹ Despite this, there are no accepted psychotropic medication treatments for this disorder, and psychotherapy is difficult at best with a patient that does not want to undergo treatment. Even with patients willing to accept treatment, improvements are difficult to achieve.²

In *Rogers v. Commissioner of Mental Health Department*, the Massachusetts Supreme Court ruled that in non-acute emergent situations, medications could not be given against the patient's consent unless they were ruled incompetent.³ Moreover, there must be treatment methods that are evidenced-based and widely accepted within the treatment community for the identified disorder leading to civil commitment; however, hoarding disorder is not generally associated with cognitive impairments, patients often demonstrate they have knowledge of their situation, and there are no accepted psychotropic medication treatments for this condition. Moreover, the hoarding behavior may be the cause of the identified danger, but is not or is rarely seen as acutely emergent.

In the situation of a hoarding-disordered patient involuntarily committed to a psychiatric unit, a number of questions arise: (1) is the person incompetent to understand their situation; (2) how can we treat them; and, (3) if there is no appropriate treatment, does that mandate release despite the continuing danger and mental illness?

If dangerous hoarding-disordered patients are not to be involuntarily held in a psychiatric unit, who in the community, if anyone, is responsible? The department of health or the police, or are the patients to be arrested or ignored despite the persistent danger? Adding to the confusion, law enforcement personnel are often encouraged to not arrest persons in the community that they suspect may be mentally ill as being incarcerated may hurt the person's ability to attain mental health care.

In this presentation, two hoarding-disordered patients who were held in a civil-psychiatric hospital for hoarding disorder are presented. In both cases, the patients were involuntarily committed; however, the court judgments did not explain how the rulings were compatible with the legal precedents established above. Both patients wished to return to their homes despite the fact that the homes were condemned by the department of health and declared too dangerous for habitation.

Hoarding disorder is a new diagnosis in the DSM-V that has gained popular attention due to the media, but the mechanics of involuntarily committing patients diagnosed with this disorder have not been sufficiently analyzed within academic forums or scientific literature. Many judges and magistrates entrusted with the gatekeeping responsibilities of civil commitment are involuntarily committing such patients without explaining how it can be appropriately done given prior legal precedents implying otherwise.

Hoarding Disorder, Involuntary Commitment, Civil Liberties

F37 Why DNA Interpretation Has Become More Challenging in Recent Years

John M. Butler, PhD, NIST, 100 Bureau Drive, MS 4701, Gaithersburg, MD 20899*

After attending this presentation, attendees will better appreciate interpretation challenges being faced by forensic DNA laboratories.

This presentation will impact the forensic science community by providing a better understanding of how improved sensitivity has brought new challenges to forensic DNA interpretation.

DNA interpretation with Short Tandem Repeat (STR) markers involves utilizing genotyping software and laboratory Standard Operating Procedures (SOPs) to evaluate Capillary Electrophoresis (CE) data. Peaks in multi-colored CE electropherograms generated as CE mobility time points are translated into DNA size information and then to allele repeat number for each STR locus. In both evidentiary and reference samples, decisions are made for each peak above an analytical threshold regarding whether or not the peak is an allele or an artifact, whether or not alleles at an STR locus can be paired to form a genotype, whether it is possible for some alleles to be missing from the data, and whether or not the sample originated from a single-source or a mixture of multiple contributors. Validation studies are essential for setting parameters used in a laboratory's SOPs to make these decisions. Guidance on validation studies and data interpretation has been provided from organizations such as the Scientific Working Group on DNA Analysis Methods and the European Network of Forensic Science Institutes.

There are two areas of forensic DNA interpretations which are particularly challenging: (1) low-level DNA samples where sensitivity is an issue; and, (2) complex mixtures where specificity is an issue. The number of contributors to a sample and the amount of DNA available for testing can impact the uncertainty or ambiguity in the conclusions drawn. In many situations involving complex results where uncertainty in the interpretation is large, the only scientifically responsible conclusion is "inconclusive" to avoid the chance of inappropriately including or excluding a potential contributor from an evidentiary result.

It is important to keep in mind that some measurements and interpretations are more reliable than others. Thus, uncertainty in measurements and interpretation should be reflected in the reports generated in a forensic case investigation. Assumptions made during the interpretation process should be documented and conveyed as clearly as possible. This documentation will aid those individuals reviewing the lab report to appropriately assess the results obtained and the conclusions drawn.

This presentation will discuss principles behind why DNA interpretation has become more challenging in recent years with an increase in sensitivity being applied by modern polymerase chain reaction amplification techniques. Approaches taken for interpretation may be subjective in some cases and therefore can become the weakest part of the overall DNA typing process. This presentation will also provide some historical perspective on the impact of improved sensitivity with DNA analysis and the desire to extend the reach of forensic DNA testing.

Forensic DNA, DNA Mixtures, DNA Sensitivity

F38 Who and What: Providing Context to a DNA Profile

John Ballantyne, PhD, University of Central Florida, Dept of Chemistry, 4000 Central Florida Boulevard, Orlando, FL 32816-2366; and Erin K. Hanson, PhD, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will learn how forensic geneticists may be able to provide contextual activity-level information pertaining to what transpired prior to the deposition of a DNA profile.

This presentation will impact the forensic science community by demonstrating the need for forensic scientists to be aware of the alleged circumstances of the crime despite the possibility of contextual bias.

I keep six honest serving-men (They taught me all I knew); Their names are What and Why and When and How and Where and Who...Rudyard Kipling

The ultimate aim of forensic scientific evidence in a criminal investigation is to help establish a fact or facts that may be at issue. The questions involve what, why, when, how, where, and who as they pertain to the people, places, and things involved in the commission of the crime. The DNA technology revolution has significantly impacted the criminal justice system in that the individual who deposited crime scene biological trace or body fluid evidence can be routinely identified. This source level information has facilitated the identification and conviction of perpetrators and the exoneration of falsely accused individuals.

The forensic DNA community has concentrated its efforts in producing for stakeholders an error-free product with, arguably, less emphasis on completeness of analysis, including trying to answer questions that go beyond identifying the source (the “who” and to a lesser extent, the “where” questions). Specifically, forensic geneticists currently are rarely in a position to provide context to the DNA profile, namely what “activity” led to the deposition of the biological material. This pertains to the “what” (and perhaps “how”) question relating to the case events. For example, consider a sexual assault on a female victim with an object (recovered from the suspect) and the victim’s DNA is recovered from the object. He could claim that the victim handled the item during a casual encounter and this explains why her DNA was present; however, the significance of this evidence would increase if the DNA could be shown to originate from vaginal cells, a circumstance that would be consistent with a sexual encounter but not with casual handling. The ability to distinguish between these alternative propositions, sexual versus social contact, might prove to be critical to the investigation and prosecution of the case. Failure to provide this critical probative information could allow perpetrators to exploit the shortcomings in routinely used body fluid identification methods in order to provide reasonable doubt regarding the true circumstances of the crime. This presentation will briefly describe new methods that permit the definitive identification of activity-level-indicating body fluids such as vaginal secretions, menstrual blood, and skin as well as blood, semen, and saliva.

There has been some discussion in the scientific literature and in the popular press that forensic scientists should be blind to the circumstances and details of the crime due to the possibility of contextual bias influencing their interpretation of the scientific data. This study argues that forensic geneticists should, in addition to identifying the source of biological material, also concern themselves with trying to help deduce what occurred. In order to effectively assess the strength to be attached to the scientific findings, the alleged circumstances need to be taken into account and the scientist needs to be aware of them. The framework for evaluative reporting is the likelihood ratio, which measures the strength of support the findings provide to discriminate between propositions of interest.

DNA Profiling Context, Body Fluid Identification, Source/Activity Level

F39 Biological Evidence Storage and Disposition: A Discussion of Legal Implications, Trends, and Policy Recommendations

Shannan Williams, MA, 100 Bureau Drive, Gaithersburg, MD 20899*

After attending this presentation, attendees will be aware of the recent deliberations of the Technical Working Group on Biological Evidence Preservation in developing recommendations to policy makers regarding the issue of biological evidence storage and disposition.

This presentation will impact the forensic science community by providing insight on the legal and policy considerations in the improvement of biological evidence storage and management.

In August of 2011, the National Institute of Justice and the National Institute of Standards and Technology's Law Enforcement Standards Office convened the first meeting of the Technical Working Group on Biological Evidence Preservation. The primary objective of the working group is to establish best practices, based in science, to reduce the premature destruction and degradation of biological evidence, thus ensuring its availability for future analysis; however, a key dimension to the work of the group is the legal and legislative landscape of biological evidence retention. Following the publication of *The Handbook on Biological Evidence* in 2013, the group agreed to produce additional recommendations geared specifically toward policy makers to facilitate the implementation of best practices within law enforcement agencies. The purpose of this presentation is to bring awareness to these issues and introduce the preliminary recommendations being proposed by the working group.

Recent headlines have highlighted significant problems with the storage of potentially exculpatory biological evidence in property and evidence storage units across the country. Court orders for the location of evidence have demonstrated inadequacies in the packaging, storage, and tracking process of some evidence. Investigations into these inadequacies reveal underlying factors such as: capacity of the storage facility; laboratory backlog; materials available for packaging; geographic distance between the collecting and storage facility; and, the selected tracking system. While preserving and readily retrieving biological evidence from adjudicated and unsolved cases is a goal and has clear benefits for all members of the criminal justice system, the management of retaining and eventually disposing of biological evidence requires that each state and jurisdiction consider the relevant legal and policy issues.

Most states have laws that provide guidance for the evidence storage and disposition process but these laws vary widely. This process may include getting a court order, district attorney approval, notification of the law enforcement agency, or notification of the defendant/defense attorney or attorneys of record. Recent Supreme Court decisions including *Melendez-Diaz v. Massachusetts* and more recently *Bullcoming v. New Mexico* set out the importance of chain-of-custody documentation and the importance of evaluating the integrity of evidence and the circumstances of testing. Creating the appropriate sanctions for evidence destroyed in violation of relevant policy and ensuring remedies for the denial of access to biological evidence are also issues under consideration by the working group based on its analyses.

Evidence, Policy, DNA

Jurisprudence Section - 2015

F40 DNA Typing: Controls and Validation Updates to Support Current Testing

Christie T. Davis, PhD, Helix Analytical, Inc, 90 Saturn Street, San Francisco, CA 94114*

After attending this presentation, attendees will learn that current controls and validation used for optimum amounts of DNA are lacking in establishing scientific practice for low amounts of DNA, which deters accuracy in obtaining and interpreting DNA typing results. Suggestions will be provided for controls and studies needed to augment current procedures.

This presentation will impact the forensic science community by providing information that will improve DNA typing accuracy. While DNA typing kits and analytical equipment have rapidly changed to allow typing of low quantities of DNA (Low Level DNA (LLD)), there has been no matching change in requirements for validation studies and controls to address additional problems that arise in typing LLD. The goal of this presentation is to present techniques and studies to strengthen current testing results.

Existing validation studies of two-person mixtures and sensitivity have demonstrated that LLD typing may exhibit known problems such as stochastic effect, founder effect, allelic dropout, and allelic drop-in. These issues become exacerbated with the use of current kits and analyzers that can operate with very low quantities of DNA, particularly when mixtures consist of more than two persons. Studies will be discussed that demonstrate that allele sharing can confuse interpretation of the number of contributors present; the data may look like two persons, but are actually three. Crime labs using data from LLD typing can address these issues through directed validation and controls. The existing validation studies do not address peak height imbalance due to allele sharing and investigation-borne contamination. Current controls do not address detection of contamination or stochastic effect in mixtures.

Currently, LLD typing is treated no differently than sufficient DNA samples with regard to testing controls. Existing controls are made up of sufficient DNA (positive amplification and Quality Control (QC)) or no DNA (negative control). LLD controls should be added, such as a low-level single-source known control and low-level mixture controls. It would be advantageous to add blind LLD mixture controls. Some labs currently set up a QC sample where the result is unknown to the analyst who then types the sample and provides the profile to the laboratory QC supervisor. It would be of minimal disruption to add an unknown LLD mixture sample.

LLD sample results are also more susceptible to contamination picked up during scene processing, during autopsies at coroner laboratories, from a victim requiring medical procedures, and during crime laboratory processing. Cases will be presented in which contamination was “proven” after the fact. Validation studies would help ascertain where conditions are poor and what steps can be taken in advance rather than in the aftermath. Mixture results are particularly problematic in determination of whether investigation-borne contamination is present and at what levels. Validation studies addressing this issue will be discussed.

Additional cleaning and testing procedures can be established at the DNA laboratory, coroner’s autopsy rooms, and other potential evidence-handling locations to predetermine what contamination sources may exist. Suggestions will be made during the presentation on possible procedures to decrease contaminating DNA. Additional validation on pipetting accuracy will ensure more accurate results. LLD sample typing is more susceptible to amplification problems due to poor pipetting skills.

Validation, Contamination, Controls

Jurisprudence Section - 2015

F41 The Discovery Motion for “Scientific Stuff:” Don’t Expect to Get It, Find It, or Recognize It (Even if You Do Get It) if You Have No Idea What You’re Looking For!

Joseph P. Bono, MA, PO Box 2509, Leesburg, VA 20177; and Ken Williams, MS, JD, New Jersey State Police, North Regional Laboratory, 1755 State Highway 46, Little Falls, NJ 07424*

The goal of this presentation is to focus on documentation which should be available through a discovery motion for review by both sides as a part of pre-trial discovery. Specific technical documents and operational protocols will be identified. The objective will be to provide a lawyer with the answer to the question: What am I looking for and what could it mean?

This presentation will impact the forensic science community by enhancing the knowledge base of what to request in a discovery motion and what to expect from the forensic science laboratory. (Since the credibility of a forensic scientist’s testimony could be inversely proportional to the number of four-syllable words which are used without an explanation in a “lawyerly discussion,” the technical jargon in this presentation will be minimized.) There are required laboratory documents which the defense should request and which the prosecution should be aware of in order that both sides can fulfill their responsibilities to the courts in evaluating the elements associated with the case at hand.

Some of the more common questions lawyers wonder about in reviewing a forensic analysis or discussing the analysis with the “expert” are: (1) what does “get it” mean; (2) do I know exactly what I am looking for or looking at; (3) why didn’t someone tell us about this; (4) what do all those big words mean and are they important; (5) how am I supposed to cross-examine an expert when I have no idea what he/she is talking about or when I don’t understand what was done in my case; and, (6) standards, what are standards?

Most forensic science laboratories in the United States have nothing to hide and issue reports which reflect conformance to standards. Most laboratories have subscribed to the oversight of external accrediting bodies and state-wide commissions to maximize the probability that everything is transparent in the management and operational aspects of valid science. Disclosure of what is happening behind those doors with signs dictating “Authorized Personnel Only” is there for the asking; however, there are times when the defense and even the prosecution should be more inquisitive in seeking answers to questions which have a legal impact on what is happening behind those locked doors. The prosecution can usually pay a visit to the laboratory for a sit-down. The reality is that these “sit downs” with the prosecution occur far too infrequently. The “other side” faces a more daunting challenge. The defense, if they want to see anything, may be asked to a court order. Sometimes there may be valid reasons for denying admission to certain part of the laboratory (like the vault) to “unauthorized personnel.” Even when the defense is allowed into the laboratory, all they will usually see are white coats, dropper bottles, flasks, microscopes, humming machines with robotic arms picking up small rubber-capped vials, and row after row of computer monitors with images of straight lines, curved lines, or columns of numbers.

The properly worded discovery motion is one effective way to obtain the answers to the most important questions. The challenge for the lawyer is this: How do you get what you need if you don’t know what you are looking for and if “you do get it,” what does it all mean? Many discovery motions are couched in terms of “give me everything you’ve got.” Even if and when “everything” is provided, the lawyer probably has no idea what “everything” (all that paper with charts and lines and paragraphs with four- to six-syllable words) really means.

So the next step is to ask for a CV or Bio and proficiency test results. Nearly everyone will recognize an academic degree or the fact that the analyst passed a proficiency test. The issue here is that this information will provide very little if anything about the “case at hand.” Most analysts have college degrees and most analysts pass a proficiency test. If they don’t pass a proficiency test, they’ve probably been “rehabilitated.” Then there are the requests for “six months of calibration and maintenance records for those machines.” Even with the reams of paper which are produced for this request, there will be little information obtained with which to evaluate the relevance, reliability, and validity of what was done in the “case at hand.”

Jurisprudence Section - 2015

The factors in determining the reliability of any scientific analysis conducted in a laboratory can be “discovered” by evaluating documentation related to how the laboratory is managed; whether the laboratory is conforming to scientific standards which have become pro-forma requirements in forensic science laboratories; whether the data in the case at hand conforms to reporting protocols; whether all of the documentation supports the conclusions; whether alternative explanations are possible for those conclusions; and, whether all of the information which may be exculpatory is being provided. A properly worded discovery motion for specific documents can provide some level of assurance that the answers to the relevant questions related to the case at hand are actually being provided, remembering that nothing is absolute. Standards do exist and conformance to those standards is the foundation of a laboratory’s credibility.

Discovery Motion, Scientific Standards, Scientific Data

F42 It's My Toy and You Can't Play With It: Defense Counsel Problems With Access to CODIS

Alissa L. Bjerkhoel, JD*, 225 Cedar Street, San Diego, CA 92101

After attending this presentation, attendees will have an overview of the origins and scope of the Combined DNA Index System (CODIS), the requirements for obtaining access to CODIS, and the obstacles defense counsel face when attempting to use this investigative tool to establish their client's innocence.

The presentation will impact the forensic science community by identifying an existing problem with CODIS access, highlighting the lack of any substantiated counterargument for the denial of such access, and proposing the need for legal reform to make CODIS equally available to defense counsel in a criminal justice system that prides itself on being fair.

Over the past two decades, DNA technology has revolutionized the nation's criminal justice system. DNA has become the foremost technique for conclusively identifying and excluding criminal suspects in cases where biological material is left at a crime scene. As of June 2014, CODIS produced over 250,000 hits which helped in nearly 239,000 investigations.¹ Thousands of courts throughout the United States have reversed convictions of people who were wrongfully convicted.² Currently, there have been 1,406 individuals exonerated in the United States.³ Of those exonerations, 317 have been the result of DNA testing, and convictions taking place as early as 1974 have later been reversed through DNA testing.⁴ Of the 317 post-conviction DNA exonerations, DNA testing has led to the identification of the true perpetrator in a staggering 152 of the cases.⁵ There can be no denial that DNA is the leading tool for convicting the guilty and exonerating the innocent.

Sadly, only nine states — Colorado, Georgia, Illinois, Maryland, Mississippi, New York, North Carolina, Ohio, and Texas — have laws giving defendants access to CODIS.⁶ Defense counsel's success in accessing CODIS in other jurisdictions tends to be the result of luck, interested law enforcement, or the kindness of prosecutors. More often than not, law enforcement and prosecutors have outright blocked defense counsel access. The typical arguments against access is that the defense has no right to access, or that access would result in the disruption of the national database system altogether. Such claims appear to be largely unfounded and concerns could be satisfactorily dealt with by proper reform. Further, the denial of access is at odds with a defendant's right to due process and the government's obligation to disclose exculpatory evidence.⁷ Steven Benjamin, the National Association of Criminal Defense Lawyers' president, said, "Science doesn't belong to the government, but they act like it does."⁸ It should not be so.

In 2009, prosecutors charged Reggie Cole with possession of a razor blade in prison; a razor blade had been found inside his prison mattress. DNA testing was performed on the razor blade and Cole was excluded. Cole motioned for the profile to be run through CODIS. The motion prompted the DNA attorney for the California Department of Justice to personally appear in the remote county where the trial was taking place to successfully oppose the motion. Uriah Courtney's case was much different. In 2005, Courtney was convicted of kidnapping, rape, and other charges. He served more than seven years in prison before a forensic profile was run through CODIS and generated a match to the true perpetrator. Unlike Cole, the county prosecutor agreed the profile generated should be run through CODIS.

Other examples highlighting defense counsel's struggle and the need for improving the criminal justice system will be discussed.

F43 “In God We Trust, All Others We Cross-Examine” — Cross-Examination in DNA Mixture Cases

Nicole Kubista, JD*, 7582 Currell Boulevard, Ste 212, Woodbury, MN 55125; and Rebecca A. Waxse, JD, 5669 147th Street, N, PO Box 548, Hugo, MN 55038

After attending this presentation, attendees will understand the theories behind cross-examination as a method for relaying information and uncovering biases and inaccuracies of this method as it relates to DNA mixtures.

This presentation will impact the forensic science community by highlighting the practical aspects of cross-examination, specifically where this tool meets and fails to meet its purpose of conveying accurate information to fact finders.

Cross-examination of witnesses is often a criminal defendant’s only hope of uncovering inaccuracies, relaying concerns, and testing the veracity of evidence against him. Depending on the initial presentation of evidence in the direct examination, cross-examination may offer a more comprehensive understanding of the evidence, allow juries to understand what parts of the analysis are subject to possible bias or multiple interpretations, help the jury assign weight and meaning to the evidence, and in some cases create confusion as to the nature of the testimony.

In the case of scientific evidence or evidence of a highly technical nature, such as DNA mixtures, the necessity for a defendant to convey the complexities internal to the case and within the forensic community is heightened. The important scientific discussions about interpretation of mixtures may make the difference between a conviction or an acquittal. Furthermore, the presentation of DNA mixture evidence may be given too much or too little weight in helping a jury decide the final outcome of a trial. Thus, for many defendants, cross-examination is the imperfect tool they must use to convey not only the complexity of the science but also the imperfections of human analysis.

For an expert witness, cross-examination is the moment where a perfectly laid out explanation of the scientific evidence is muddled by an attorney. The procedural demand for short explanations and “yes” or “no” answers leaves many witnesses with a sense that all the necessary information was not conveyed to the fact finder or worse, misinformation was relayed to the jury. This frustrating process appears to be in direct opposition to properly conveying scientific knowledge.

When it comes to explaining DNA mixtures, attorneys, witnesses, and defendants find themselves competing to control the information relayed to the fact finder. The tension between these parties is often complicated by the lack of limits on admissibility of scientific evidence. Without proper limits, both direct and cross-examination may attempt to push a witness into unsupported or contested scientific positions. This presentation will examine actual trial transcripts and draw from examples of DNA mixture litigation in criminal cases.

J. Wigmore in *Wigmore on Evidence* stated that cross-examination is “beyond any doubt the greatest legal engine ever invented for the discovery of truth.”¹ Other legal scholars view cross-examination as the principal means by which biases or inaccuracies of witnesses are uncovered; however, the real-world application of these theories creates highly variable results especially when a complex DNA mixture is the subject of cross-examination. Witnesses, defendants, attorneys, and everyone involved may feel frustrated because important information has been obscured or was unclearly communicated.

F44 Interpreting Gobbledygook — What Lawyers and Forensic Scientists Can Do to Communicate Clearly About Scientific Evidence to a Jury

Nicole Kubista, JD, 7582 Currell Boulevard, Ste 212, Woodbury, MN 55125; and Rebecca A. Waxse, JD, 5669 147th Street, N, PO Box 548, Hugo, MN 55038*

After attending this presentation, attendees will understand the challenges that lawyers and forensic scientists face in trying to effectively communicate scientific evidence to a jury. Attendees will learn what works and does not work when communicating about scientific evidence and will receive practical suggestions as to the most effective means of communicating scientific evidence to a jury.

This presentation will impact the forensic science community by facilitating a discussion on what needs to be done by both lawyers and forensic scientists to increase the effectiveness of forensic science communication to a jury. This will enable juries to be able to use the evidence in a meaningful manner and will promote more informed results.

Lawyers and forensic scientists have all been told how juries give science in the courtroom a great deal of weight. Judges also place great weight on science. Science can be a very powerful tool in a court case; however, to best utilize this tool effectively, both lawyers and forensic scientists must be able to communicate about the science in an effective manner. Lawyers and forensic scientists each face challenges to ensure that the science is communicated clearly in the courtroom setting.

If a lawyer presenting a forensic scientist witness does not understand the language being used by the witness, the lawyer is not going to be able to ensure that the jury is understanding the witness' message. In addition, if a lawyer is cross-examining a forensic scientist witness and does not understand the language being used by the witness, the lawyer is not going to be able properly cross-examine the witness. To properly allow a witness to communicate scientific information, the lawyer must understand the information. The lawyer must be able to clearly communicate the scientific language and work to make sure the jury understands that language.

A forensic scientist's role in the courtroom is to clearly communicate how his or her testing was conducted and the results of his or her testing. Most forensic scientists could easily explain his or her process and results to other scientists without any issues; however, in court, the forensic scientist is not explaining the process and results to other scientists — the forensic scientist is explaining it to a jury. To complicate this further, the forensic scientist does not get to just get up and speak. He or she must answer the questions of the lawyers. This can be a very awkward manner in which to communicate information and often, due to this awkward manner of communication, a forensic scientist is not able to clearly communicate.

Forensic science has an important role in our justice system. This presentation will address what lawyers and forensic scientists need to do to ensure that the information is presented in an understandable manner so it can be used in the most effective way within the courtroom.

Language, Scientific Evidence, Jury

F45 Development of Small-Group Forensic Counsel in Greater Minnesota: Forensic Case Review in the Boonies

Gregory B. Davis, JD, 416 S 6th Street, Brainerd, MN 56401; and Carly S. Vosacek, JD*, 416 S 6th Street, Brainerd, MN 56401*

After attending this presentation, attendees will understand the basic requirements, goals, and benefits of the establishment of a small, geographic-centered, forensic criminal case-review program for defense counsel. In addition, attendees will understand how such a group fits within a larger-scale statewide forensic program for defense counsel.

This presentation will impact the forensic science community by demonstrating the importance of initial and immediate forensic case review. This presentation will also demonstrate the need for involvement by defense counsel at the commencement of representation and throughout trial. Finally, this presentation will show how working within a small forensic unit assists in providing effective assistance of counsel and improved client representation.

In Minnesota's Ninth Judicial District, the public defender's office has created a template whereby cases involving forensic evidence are being identified immediately and assigned to individual lawyers who are trained in forensic litigation. There are six lawyers in the Minnesota Ninth Judicial District public defender's office who are trained in forensic litigation and comprise the unit. These individual lawyers act as a supporting mechanism for the trial counsel and work together as a group to review the cases and are also able to take part in larger statewide forensic training.

Although there have been many calls for the education and training of legal counsel in forensic fields, the actual implementation of programs are, for many, still aspirational rather than actuality. The initiation of a small forensic counsel group to review, assist, and advise trial counsel in greater Minnesota has provided a client base located in a geographically large area with a benefit that was previously much more difficult provide.

The establishment of small forensic groups to assist in initial review and assistance to trial counsel is now a necessity, rather than an option, for representation. With the widespread expansion and access of prosecution offices for inclusion of the forensic analysis of evidence, it is incumbent for defense counsel to provide for knowledgeable review of case-specific forensic evidentiary issues.

The involvement of forensic counsel at the onset of a criminal case provides for better representation and trial preparation for the individual criminal defendant because forensic issues are not only being identified, but actually being reviewed for issues that may directly affect the outcome of a client's criminal case, while also providing feedback and information with regard to the number of forensic cases being seen in a particular jurisdiction and related benefits because of forensic counsel involvement.

The specific challenges of a large geographic area of responsibility and non-centralized forensic counsel provides challenges that have been countered through the use and application of several technological issues. From simply conducting meetings or communicating through video conferencing, to large file-sharing programs, to detailed computer review of raw forensic data, technology is a cornerstone to a forensic group and an area that will need continual updating and training.

In conclusion, ensuring review of forensic case files for criminal defendants is essential in providing effective legal defense services for individual clients. Absent such involvement and review of individual forensic case issues, clients cannot be assured an adequate and effective defense, to which each is entitled.

Trials, Training, DNA

Jurisprudence Section - 2015

F46 In or Out? What is the Threshold for Admissibility?

Julie Maxwell, JD, 510 15th Street, NW, Rochester, MN 55901*

After attending this presentation, attendees will be more prepared to answer the question, what is the threshold for admissibility? Attendees will gain knowledge and an understanding about some of the tools which the forensic community uses and whether those tools are being used for investigative versus evidentiary purposes.

This presentation will impact the forensic science community by prompting defense and prosecution attorneys to be more careful in their examination of information gathered from the use of forensic tools. This presentation will urge attorneys to make a determination of whether information is being used merely as part of the overall investigation by law enforcement or whether that information is to be used at trial for acquittal or conviction.

The admissibility of forensic evidence has always created some challenging questions for the bench and bar. To be admissible, evidence must meet the standards set forth in the rules of evidence as well as the standards articulated by *Frye* and more recently, *Daubert*. Yet outside of the types of forensic evidence that meet these standards, there are forensic tools used for investigative purposes which are not intended to be and should not be considered evidentiary in nature. For example, the use of polygraphs to establish whether an individual is lying or preliminary breath tests to establish a blood alcohol concentration.

This presentation will explore an examination of the Rules of Evidence and the *Frye* and *Daubert* standards to help understand what the criteria are for evidence to be deemed admissible. It will further explore the category of forensic tools that are designed for “investigative purposes” and how these are and/or should be treated by criminal courts.

What makes a test “presumptive” versus “confirmatory” and why are these distinctions important? This presentation will explore the admissibility of other tools such as narcotic identification kits and “hits” to the DNA database. It will look at examples where these distinctions of “presumptive” and “confirmatory” are not fully appreciated by lawyers and the problems created when attorneys and judges do not think in these terms. The idea that “presumptive” does not equal “truth” must be considered when determining admissibility or inadmissibility.

The 2009 National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Path Forward*, found that lawyers “often lack the scientific expertise necessary to comprehend and evaluate forensic evidence.” Even six years later, this observation continues to ring true. Lawyers still struggle with how to understand and evaluate forensic evidence. Exploring the distinctions between what can and should be used for investigative purpose and whether such tools should be admissible may lead to a richer understanding of the interplay between forensic science and the courtroom, which can benefit the entire criminal justice system.

F48 The Validity of Enzymatic Assay for Blood Alcohol Content (BAC) Determinations

Josh D. Lee, JD*, Ward, Lee & Coats, PLC, PO Box 352, Vinita, OK 74301; and Justin J. McShane, JD*, 3601 Vartain Way, Ste B, Harrisburg, PA 17110-9440

The goal of this presentation is to focus on the scientific issues concerning the limitations of Enzymatic Immunoassay (EIA) -based ethanol testing as well as the legal sufficiency and admissibility challenges that have occurred across the United States.

This presentation will impact the forensic science community by further spurring discussion in the legal community about the continued suitability of this assay when other, more specific assays are available.

BAC testing is crucially important in a Driving Under the Influence (DUI) prosecution. It is one of the fundamental pieces of, and often the only, evidence against a citizen who has been accused of a DUI. In the United States, there are three different types of methods used to provide for a BAC: breath testing, gas chromatography, and EIA (sometimes referred to simply as “hospital blood”).

Scientifically educated DUI defense attorneys have been successfully challenging the admissibility and the sufficiency of EIA evidence to form a conviction on a *per se* DUI BAC offense. These successful challenges simply point out the known limitations of the assay. The publication of these successful challenges has led many hospitals that offered EIA-based testing for BAC purposes to stop. In other jurisdictions, district attorney’s offices have ceased using EIA-based evidence due to various reasons such as an increase in costs due to the need to employ an expert to try to interpret and defend the EIA-based BAC evidence, a sense of justice and ethics, as well as the lack of expertise in their offices in successfully prosecuting such cases.

Mean ratio	± SD	Range	Sample Number	Reference
1.11	± 0.02	1.08-1.16	4	Hodgson, et al. 1985
1.14	± 0.02	1.09-1.18	50	Winek, et al. 1987
1.10	± 0.03	1.03-1.24	17	Jones, et al. 1990
1.15	± 0.041	0.88-1.59	211	Rainey 1993
1.14	± 0.04	1.04-1.26	235	Charlebois 1996
1.16	N/A	1.08-1.21	N/A	Iffland, et al. 1999

Table 1. Summary of alcohol concentration ratios for plasma and serum comparisons to whole blood

This chart shows the wide range of conversion factors. Such a wide range illustrates the difficulty in attempting to convert non-whole blood results to whole blood expressions. Additionally, it demonstrates that there is insufficient agreement in the scientific community as to an acceptable range of values.

It is incumbent upon the legal and medical communities to begin to understand the fundamental differences in the uses of BAC testing. In situations that require high degrees of confidence in the measures of BAC, such as in the case of criminal trials, only the most accurate and selective methods should be used to ensure that the guilty are not needlessly acquitted nor are individuals falsely convicted.

Enzymatic Assay, DUI, BAC

Jurisprudence Section - 2015

F49 Driving Under the Influence of Drugs in Florida

Nicholas B. Tiscione, MS*, 3228 Gun Club Road, West Palm Beach, FL 33406; Xiaoqin Shan, PhD, Palm Beach County SO, Crime Laboratory, 3228 Gun Club Road, West Palm Beach, FL 33406; and Dustin Tate Yeatman, MS, 3228 Gun Club Road, West Palm Beach, FL 33406

After attending this presentation, attendees will understand the potential disadvantages of Driving Under the Influence of Drugs (DUID) laws that list specific compounds rather than using more general “any impairing substance” language.

This presentation will impact the forensic science community by offering insight into challenges of combating the incidence of DUID when specific compounds are listed in laws. Overall statistics as well as specific case examples will be presented.

The laws in Florida for DUID list specific compounds (controlled drugs) that must be proven to cause the observed impairment. Many prescription and over-the-counter drugs that can cause significant impairment are not included in this list. Therefore, according to Florida law, one is not guilty of driving under the influence if the observed impairment is due to a drug not listed in the Florida statutes. The Palm Beach County Sheriff’s Office (PBSO) Toxicology Unit analyzes and reports all impairing substances, within the capabilities of the laboratory, regardless of the scheduled status of the drug.

In Florida, urine samples are routinely collected when breath alcohol results are below 0.08g/210L for DUID investigations. Blood samples are only collected when it is impossible or impractical to perform a breath alcohol test or if there is a serious bodily injury or death involved. From January 2007 to January 2014, 1,361 urine specimens and 914 blood specimens were analyzed for drugs by the PBSO Toxicology Unit. Urine specimens were screened by a basic extraction with scan Gas Chromatography/Mass Spectrometry (GC/MS) and an eight-panel Enzyme-Linked Immuno-Sorbent Assay (ELISA) for barbiturates, benzodiazepines, buprenorphine (2013 to 2014), carisoprodol, cocaine/Benzoyllecgonine (BE), opiates, oxycodone/oxymorphone, and cannabinoids. Blood specimens were screened by a basic extraction with scan GC/MS and a ten-panel ELISA for amphetamines, barbiturates, benzodiazepines, buprenorphine (2013 to 2014), carisoprodol, cocaine/BE, methamphetamines, opiates, oxycodone/oxymorphone, and cannabinoids. All positive results were confirmed with GC/MS.

Over the past seven years, 25% of all drug-positive blood specimens and 46% of all drug-positive urine specimens contained at least one non-controlled drug, often mixed with controlled drugs. The top ten non-controlled drugs excluding Selective Serotonin Reuptake Inhibitors (SSRIs) identified in both blood and urine are listed in Table I. The driving under the influence charges in many if not most of those cases with non-controlled drugs were either dropped or not even filed.

Table I. Top ten non-controlled drugs identified in blood and urine (excluding SSRIs)

Blood			Urine		
Analyte	# of Cases	% of Positive Cases	Analyte	# of Cases	% of Positive Cases
Diphenhydramine	37	5.4%	Diphenhydramine	112	9.7%
Zolpidem	29	4.3%	Zolpidem	83	7.2%
Tramadol	17	2.5%	(d) Methorphan	52	4.5%
(d) Methorphan	15	2.2%	Cyclobenzaprine	46	4.0%
Cyclobenzaprine	10	1.5%	Tramadol	41	3.6%
Trazodone	9	1.3%	Trazodone	40	3.5%
Topiramate	9	1.3%	Chlorpheniramine	32	2.8%
Chlorpheniramine	6	0.9%	Doxylamine	32	2.8%
Lamotrigine	6	0.9%	Nortriptyline	22	1.9%
Phenytoin	5	0.7%	Amitriptyline	20	1.7%

F50 Evaluating Forensic Evidence in Drug Impairment Cases: Pitfalls and Complexities of Testimony by Non-Medical Witnesses

*Jeremy C. Brehmer, JD**, Middlebrook & Brehmer, LLP, 5201 California Avenue, Ste 450, Bakersfield, CA 93309; and *Josh D. Lee, JD**, Ward, Lee & Coats, PLC, PO Box 352, Vinita, OK 74301

The goal of this presentation is to provide attendees with an overview of: (1) why non-medical witness testimony interpreting human performance as drug impairment can lead to an unfair application of justice; and, (2) the common pharmacokinetic and pharmacodynamic issues of the seven distinct drug classifications used in American jurisprudence.

This presentation will impact the forensic science community by explaining how, in order to accurately determine if a human subject is impaired by drugs, the person making the determination must be educated in the interactions of the chemicals found in the drugs with the biological receptors in the brain (pharmacodynamics). The person making the determination must also understand fully how the chemicals from the drugs are absorbed, distributed, and eliminated in the body (pharmacokinetics) and how long that process takes.

Drugs in the body can be broadly classified into two types: (1) zero order drugs; and, (2) non-zero-order drugs. Essentially, this means that for zero-order drugs, the elimination rate is constant and not dependent on any biological variability. Conversely, the elimination in non-zero-order drugs is variable. This non-zero classification is a significant departure from that of ethanol metabolism. Absent a complete subject (patient) medical history, the reported drug concentrations and subjective observations reported by the non-medical witness are incomplete and can be misleading.

Pharmacodynamic effects reported by a non-medical witness require considerable education about the central nervous system's physiology and neurotransmission. The witness must be able to testify about the synaptic vesicle, reuptake, receptors, and the transfer through the synaptic cleft. The witness must also be able to distinguish between the various sites of synthesis as they relate to the class of transmitter.

To understand the significance of transmission differences, the witness must recognize that some drugs stimulate the receptor by fooling the neurotransmitter to respond. Alternatively, another type of drug may depress the site by acting as a wall, preventing the cell from stimulation or engaging with its receptor. The individual responses of both stimulation and depression of neurotransmitters vary from person to person. This makes dosage and interpretation of toxicology report values variable and complex. The non-medical witness must recognize that drug variability is affected by dosage, route of ingestion, length of time taking drug, interaction with other drugs, drug potency, gender, body mass, age, and genetic makeup, including ethnicity.

The non-medical witness must also understand the bioavailability of the drug. This means that the witness must understand what percentage of the consumed drug is free vs. bound. How much of the drug reaches the effected receptor is dependent on how the drug is ingested. Was it a tablet taken orally, an injection administered intramuscularly or intravenously, etc.? Is the drug protein-bound? Is there more than one drug of similar polarity attempting to bind with the same protein or is the drug free to enter the cell? These are all questions that the witness must be able to answer if they are attempting to correlate a drug level with impairment.

Opinion testimony about a drug concentration by a witness that does not possess the necessary medical background in understanding of free and bound drugs and the specifics about the individual drug polarities can be misleading to the jury and the judge. A hearing to determine the admissibility of such opinion evidence should always be required but often is overlooked and instead labeled as fodder for cross-examination.

The non-medical witness opinion evidence is often based on an incomplete scientific picture. This fact requires that the attorneys and judges educate themselves about the considerable limitations of the drug recognition evaluation and stop unequivocal testimony that a certain drug concentration in the body equals impairment universally without considering any medical or physiological information about the individual subject.

Non-Medical Witness Testimony, Pharmacodynamics, Pharmacokinetics

F51 Forensic Sciences as a Contributor to Miscarriages of Justice in Western Europe

Joelle V. Vuille, PhD, University of Neuchatel, School of Law, Neuchatel 2000, SWITZERLAND*

After attending this presentation, attendees will understand how inquisitorial and adversarial criminal justice systems operate with regard to forensic science evidence. Attendees will also understand how the specificities of each system affect the use of scientific evidence in criminal prosecutions, both positively and negatively.

This presentation will impact the forensic science community by helping build a context in which the role of scientific evidence in miscarriages of justice in the United States and in Europe can be better understood. This will be accomplished by highlighting structural and operational differences between inquisitorial and adversarial criminal justice systems and linking them to the use of scientific evidence in those jurisdictions.

After being hailed as a miracle tool in the fight against crime, the forensic sciences have slowly come under scrutiny as a possible contributor to miscarriages of justice in the United States. Between honest mistakes, voluntary manipulations, and a general lack of experimental validation, many cases can now attest to the role played by the various forensic sciences in the prosecution and conviction of the innocent; however, the phenomenon has so far curiously remained practically unknown in Western Europe. Only a handful of cases have come to light in which flawed scientific evidence contributed to a miscarriage of justice. How can one explain such a stark contrast?

Two main hypotheses will be considered: (1) it could simply be that forensic science has never been identified as a contributor to miscarriages of justice in Western Europe, but plays an important part nonetheless; the reasons possibly preventing the detection of errors will be discussed, such as varying policies in the preservation of evidence, lengths of sentences, attitudes of defense attorneys, etc.; (2) forensic science does not contribute to miscarriages of justice in Europe in the same proportions as in the United States. Different variables could be at play in this context, such as the structure of the adversarial and inquisitorial criminal justice systems, the possibilities of appeal and review of convictions, the funding of laboratories, the education of scientists, and the ways in which forensic science is used by law enforcement to solve crimes.

The goal of this presentation will be to discuss these various propositions and present the (minimal) data available in Western Europe on this topic. The relevance of various research options will be debated, as well as the potential impact of such a line of research on the field.

Miscarriage of Justice, Adversarialism, Inquisitorialism

F52 Defending Veterans: Teaching Juries the True Costs of War, Post-Traumatic Stress Disorder (PTSD), Adrenaline Addiction, and Deadly Drug Cocktails

*Jose A. Baez, JD**, 2020 Ponce De Leon Boulevard, Miami, FL 33134; and *Donald E. Shelton, JD, PhD*, 500 S Harris Street, Saline, MI 48176

After attending this presentation, attendees will learn about the nature of conveying to juries the psychology of returning from war, toxicological challenges, and overcoming bias against veterans in the criminal justice system.

This presentation will impact the forensic science community by informing forensic science practitioners, lawyers, and other key criminal justice system stakeholders how to effectively tell a veteran's story to judges and juries.

This presentation will provide better understanding of the challenges facing many veterans returning from war when they enter our criminal justice system. According to Department of Justice statistics in 2004, one in ten of all the inmates in the United States have served in the military. One out of every five combat veterans returning from war is diagnosed with PTSD. As one commentator stated: "A certain number of veterans suffering from mental-health issues will, invariably, end up in jail or prison. After Vietnam, the number of inmates with prior military service rose steadily until reaching a peak in 1985, when more than one in five was a veteran. By 1988, more than half of all Vietnam veterans diagnosed with PTSD reported that they had been arrested; more than one-third reported they had been arrested multiple times. Today veterans' advocates fear that, unless they receive proper support, a similar epidemic may befall soldiers returning from Iraq and Afghanistan."

Other veterans suffer from anxiety, drug, and even adrenalin addiction. This has prompted the emergence of specialty "veterans' courts" popping up across the country in state and federal jurisdictions, often with grant assistance from the government. Unfortunately, these intensive programs do not normally accept those veterans charged with violent crimes, leaving veterans to face judges and juries while dealing with a myriad of psychological and toxicological issues.

This presentation will discuss the landmark case of *United States v. Gabriel Brown*, a former Green Beret sniper turned serial bank robber, as well as other cases that shed light on the best practices on identifying and presenting to judges and juries the stories of those soldiers who went from fighting for our freedom to fighting for their very own. Best practices related to presenting mitigating information to judges and juries will be discussed.

Veterans, PTSD, Adrenaline Addiction

F53 Full-Scale Intelligence Quotient Test Scores and the Impropriety of “Ethnic (or Socio-Economic) Adjustment” in *Atkins* Cases

Robert M. Sanger, JD*, Sanger Swysen & Dunkle, 125 E De La Guerra Street, Ste 102, Santa Barbara, CA 93101

After attending this presentation, attendees will gain new information regarding developments in epigenetics which relate to the validity of Full-Scale Intelligence Quotient (FSIQ) scores in determining intellectual disability for the purpose of eligibility of a criminal defendant to be executed if otherwise subject to the death penalty.

This presentation will impact the forensic science community by squarely challenging the scientific validity of testimony accepted by the courts — most recently, the California Supreme Court — to the effect that the FSIQ scores of African American defendants should be “ethnically adjusted” to make such defendants eligible to be executed.

In certain capital cases, a defendant who qualifies as “intellectually disabled” (“mentally retarded”) cannot be executed under the Constitution as held by the United States Supreme Court in the *Atkins* case. The first criterion of the legal definition of “intellectual disability” is a limitation in intellectual ability, primarily as measured by standardized tests of the person’s FSIQ. If the FSIQ score is two standard deviations below the norm and if the person meets the other two criteria (deficits in adaptive functioning and onset before age 18), the person cannot be executed. Failure to meet any of the criteria, including this first criterion based on FSIQ, generally means that the person will not qualify as “intellectually disabled” and, if otherwise subject to the death penalty, can be executed.

In cases in which the defendant is African American, prosecutors have recently proffered “expert” testimony that the defendant’s scores should be “ethnically adjusted.” The “adjustment” adds five to 15 points to the defendant’s FSIQ. In stark terms, this means that given two identically situated defendants with identical FSIQ scores, one Black and the other White, the government can execute the Black defendant and not the White defendant. This process of “ethnically adjusting” the FSIQ scores of African Americans has been accepted by some courts including, most recently, the Supreme Court of California.

This presentation will establish that “ethnic adjustment” is not supported by the scientific evidence. Deviations from the norm of various cohorts — specifically considered here, those of African Americans — are not explained by “ethnicity.” Instead, established research shows that the deviation from the norm is related to socio-economic deprivation which has an unfortunate sociological correlation with race. In other words, race in this context is a proxy for socio-economic deprivation.

That fact has not ended the controversy. Instead, certain prosecution experts have modified their testimony to claim that there should still be an upward adjustment for defendants (disproportionately African American) who lived in poor socio-economic circumstances. This argument is based on the contention that such defendants are “poor test takers” and that the deficit in the FSIQ score is learned/behavioral, not phenotypical/biological and therefore not a limitation. The result, according to these experts, is to add the five to 15 points which, again, permits the government to execute such defendants.

This presentation will review significant scientific evidence that supports the hypothesis that the lower IQ scores of the cohort of people who have suffered childhood abuse, neglect, stress, poverty, and trauma are epigenetic. In fact, exposure to such factors may engender multigenerational epigenetic effects. The lower IQ scores of the cohort of people who have suffered childhood abuse, neglect, stress, poverty, and trauma have a biological basis and therefore a physical limitation on intellectual disability, not a transient behavioral impairment in test taking.

This presentation will discuss the scientific literature documenting epigenetic effects of abuse, neglect, stress, poverty, and trauma resulting in changes in the pattern of gene expression. Longitudinal studies have shown that these effects are heritable to children and even grandchildren. These changes are in addition to other adverse biological influences like exposure to toxins in poorer environments and to the effects of fetal alcohol spectrum disorder and other insults to the fetus *in utero*.

Based on the scientific evidence, it is not proper to “ethnically” or “socio-economically” adjust the FSIQ scores of defendants. Epigenetic effects on genomic imprinting biologically alter cell development which can contribute to the intellectual disability reflected in FSIQ scores within the meaning of the *Atkins* case, preventing execution of the intellectually disabled. This presentation suggests that further research needs to be done; however, what is known right now specifically conflicts with the hypothesis of “ethnic (or socio-economic) adjustment.”

Death Penalty, FSIQ, *Atkins*

F55 Sexual Abuse Case Study — Forensic Science and the Age of Social Media

Brian C. Zobel, JD, PO Box 70, Fenton, MI 48430*

The goal of this presentation is to demonstrate the effectiveness of the forensic sciences in identifying fabricated testimony.

This presentation will impact the forensic science community by challenging attorneys to analyze their cases with greater sensitivity to potential forensic science issues.

Several forensic disciplines contributed to exposing false accusations in this case of alleged sexual abuse. Voluminous records of text messages provided the defense with extremely fine detail concerning the complainant's allegations; scrutiny of these messages revealed the stories to be impossible.

The complainant was 18 years old and living at her parents' home after graduation from high school. One day, she appeared at a sheriff's department substation accompanied by two friends. One of the friends advised that the complainant had been sexually abused by her father; the police received several pages of Facebook® messages in which the complainant described being raped. The complainant was unwilling to speak with detectives, but eventually wrote several statements describing sexual abuse. Her father was arrested and the complainant's siblings, aged 17 years old and 12 years old, were taken under court jurisdiction.

Detectives obtained a search warrant for the complainant's Facebook® account and more than 5,000 pages of records were produced. The messages described unprotected vaginal, oral, and anal penetrations that included ejaculation. This was to have taken place in the family home on a daily basis over a period of one-and-one-half years.

Interviewed using standardized child abuse investigative techniques, the siblings denied that any abuse or improper touching had occurred. At the home, only one suspected biological stain was located; collected from an old mattress in the basement, the stain tested negative for seminal fluid.

The prosecution proceeded to preliminary examination. The complainant's testimony was contradictory, but the matter was bound over for trial on several counts of sexual assault. The defense investigation then focused on the details contained in the text messages. The complainant described being beaten and kicked on numerous occasions. In one incident she claimed she was kicked so badly that she suffered extensive bruising, possible broken ribs, and missed "like three weeks of school." Attendance records showed she never missed more than two consecutive days of school.

The complainant described being forced to take Valium® and Vicodin®. Her descriptions of the effects of these drugs included violent seizures and colorful hallucinations. A toxicologist and neuropsychopharmacologist concluded the complainant's descriptions were inconsistent with the known effects of these drugs. Records subpoenaed from the Michigan Automated Prescription System confirmed that neither parent had prescriptions for any controlled substances for the relevant time period. When the home was originally searched by police, no prescription drugs had been found.

A recurring theme was that the complainant's father would drag her to the basement, lock her in, and sexually assault her. She described being locked in the basement all night. Examination by the defense crime scene investigator revealed that it was impossible to lock a person in the basement. There was no lock, latch, or hook of any kind on the door. The family home was a 1,200-square-foot dwelling. Examined with specific-wavelength ultraviolet light, the interior exhibited patterns of biological staining consistent with habitation by five people, two dogs, and a housecat. There were no biological stains consistent with the complainant's stories of sexual assault having occurred in the complainant's bedroom, the family room, and basement.

Reports from the defense experts were furnished to the prosecution. The prosecutor met with the complainant and discussed the findings. The complainant admitted to fabricating the stories and all charges were dismissed. At that point, it was unnecessary to explore how the complainant came to invent the stories; however, had the case proceeded to trial, it would have been useful to have employed a forensic psychiatrist to assist in crafting the cross-examination of the complainant.

In testing the credibility of witnesses, attorneys would do well to consider all the tools of forensic science at their disposal. The proactive employment of forensic science professionals gives lawyers the power to expose fabricated testimony that might otherwise go undetected.

Fabricated Testimony, Biological Stain Detection, Neuropsychopharmacology

Jurisprudence Section - 2015

F56 Digital Evidence 101 — The Evidentiary Value of Digital Evidence: The Impact of Digital Evidence on the Investigation and Brief of Evidence

Paul Reedy, BS, DC Department of Forensic Sciences, 401 E Street, SW, Washington, DC 20024*

The goal of this presentation is to assist the forensic science community in understanding recent developments in information and communications technology, its use by perpetrators and victims in the context of criminal activity, and its evidentiary value in investigations and criminal proceedings.

This presentation will impact the forensic science community by providing attendees with a practical understanding of the role of information technology in various criminal activities plus anticipation of possible future directions.

Information (and communications) technology is ubiquitous to modern human existence. It follows that this technology is involved in nearly every facet of human activity, including criminal activity, whether it is simply the act of a person carrying a phone, a computer used to transact business, or a device that informs about an individual's state of mind and interests. Consequently, any investigation of criminal activity will potentially have lines of inquiry that include digital evidence. Digital evidence can be used for the investigation of homicide, extortion, assault, sexual assault, online child exploitation, stalking and intimidation, fraud, arson, sudden infant death syndrome, and others; it can include exculpatory as well as inculpatory evidence.

It is no secret that information technology evolves at a rapid rate with the occasional revolution thrown in for good measure. Criminals are notorious for being early adopters of technology, comfortable in the knowledge that law enforcement agencies will struggle to attain the capability and capacity to keep up.

The challenge for digital evidence experts is understanding and deciphering new technologies, including "the latest app," as critical evidence is invariably present in these new formats. The digital evidence analyst must be sufficiently qualified and experienced to reflect an understanding of the evidence under examination.

The challenge for the prosecutor is to understand the probative value of the evidence and to ensure that it is presented in a manner that is easily understood by the court.

The challenge for the defense counsel is to understand the nature of the evidence under examination, identify any insufficiencies in the forensic examination that lead the conclusions, and to identify alternative credible hypotheses based on the available evidence.

This presentation will provide descriptions of places digital evidence may be located; several case examples where digital evidence is critical to, or augments, the investigation and/or brief of evidence; the applicability of international standards to digital evidence; anticipated developments in information technology; and, some introductory remarks concerning the current legal environment.

Digital, Evidentiary, Case

G1 Non-Traditional Positive Dental Identification

Laura P. Moses Smalley, DMD, University General Dentistry at UT Medical Center, 1930 Alcoa Highway, Bldg A, Ste 340, Knoxville, TN 37920; Michael P. Tabor, DDS, 310 23rd Avenue, N, Nashville, TN 37203; Richard A. Weems, DMD, MS, 592 Oakline Drive, Birmingham, AL 35226; Lee Wilson, DMD, UT Med Center Knoxville, Dept of General Dentistry, Medical Bldg A, Ste 340, 1930 Alcoa Highway, Knoxville, TN 37920; Darinka Mileusnic-Polchan, MD, PhD, UTMCK, Dept of Pathology, 1924 Alcoa Highway, Knoxville, TN 37920; and Murray K. Marks, PhD, University of Tennessee, Dept of General Dentistry, 1930 Alcoa Highway, Bldg A, Ste 340, Knoxville, TN 37920*

After attending this presentation, attendees will understand both traditionally utilized methods used in the positive identification process and non-traditional normal anatomical variants and pathological conditions in dento-facial remains and restorations that may provide a means of dental identification.

This presentation will impact the forensic science community by demonstrating non-traditional dento-facial therapeutic evidence as well as normal and abnormal anatomical evidence that may provide forensic odontologists with successful dental identifications.

Positive identification of the decomposed, skeletal, disfigured, or incinerated victim is the goal of forensic odontology and the foremost requirement of forensic pathology. Routine positive identification methods rely on tried and true comparison of antemortem to postmortem radiographs for restoration assessment. Such identifications are only as reliable as antemortem radiographic records, which document those dental and alveolar conditions as well as different composite resin materials, amalgams, gold inlays, endodontic conditions, and prosthodontic devices; however, at times the forensic dentist does not have those restorations in the decedent's mouth. The oral cavity may present as edentulous or contain 32 virgin teeth resulting in documentation of crown and root and/or alveolar bone peculiarities. Frequently, a more non-traditional method of comparing other unique conditions not related to restorative materials may be used.

The forensic dentist can utilize some quite unusual means of comparisons, such as amalgam tattooing, in a pattern reproducible in the postmortem radiograph. Endodontic sealer "poof" marks have been used for identification purposes where root canal sealer extruded from the apical foramen, displaying an unusual shape useful with antemortem-postmortem radiographic comparison.

Occasions also arise where oral surgeons reapproximate jaw fractures with metal stabilizing plates that exhibit unusual shapes, allowing forensic dentists to compare X-rays of like kind from the decedent. With numerous types and brands of implants on the market today, the structure of the implant can even be used, especially those from decades ago where endosseous blade implants exhibited various shapes and designs of the device's struts. These can readily provide an interesting basis for comparison.

Further examples will be demonstrated where an edentulous decedent was found wearing a broken upper denture, with a rather large piece of the denture missing. No other identifying characteristics could be discovered. Several months later, detectives were interviewing a family who had reported a missing person. The family related that their missing family member was edentulous and when shown the discovered denture fragment found on the body, did allege that the shape of the denture looked similar to the decedent's smile; however, this is not conclusive evidence, but rather a suggestive clue that would encourage investigators to look further.

In searching through the personal effects of the decedent, a denture fragment was found in the bathroom drawer, which was used to reapproximate the main denture fragment found on the body of the decedent. The fracture halves, which were irregular and jagged, matched perfectly. With the fracture lines of the two denture halves from two different locations, one from inside the house of the missing person and the other at the crime scene miles away, enough information was provided for the forensic odontologist and the medical examiner to confirm identity of the body.

Several comparisons have been submitted showing iatrogenic conditions such as a broken bur embedded within the alveolus or a separated endodontic file retained in the jaw. These less-often-used criteria are equally discriminating in securing positive identification.

Attendees will recognize several unorthodox means available to positively identify victims that have seldom been used. These cases will challenge the attendee/forensic scientist to delve further into the possibilities of unusual identifying characteristics.

Positive Identification, Amalgam Tattooing, Endodontic "Poof"

G2 X-Ray Photoelectron Spectroscopy (XPS) Analysis of Etched Dental Crown Metal Surfaces Demonstrates Prior Immersion in Hydrochloric Acid

Alexander S. Forrest, MDS*, Griffith University Nathan Campus, School of Natural Sciences, Griffith Sciences, 170 Kessels Road, Nathan, Queensland 4111, AUSTRALIA; and Barry Wood, PhD, The University of Queensland, Centre for Microscopy and Microanalysis, St Lucia 4067, AUSTRALIA

After attending this presentation, attendees will be aware of a technique that will allow for quantitative elemental analysis of material surfaces with the ability to determine oxidation states and infer molecular structure. This technique has been used in this study to determine that the specific corrosive in which a dental crown was immersed was hydrochloric acid. It may have uses in other forensic situations in which quantitative surface analysis becomes important.

This presentation will impact the forensic science community by illustrating the use of a technique that potentially extends the analytical repertoire available to forensic odontologists and other practitioners.

Four distinctive dental Porcelain Fused to Metal (PFM) crown artifacts were received in connection with a forensic matter. It was suspected that these crowns had been immersed in hydrochloric acid for seven days. Previous analysis using scanning electron microscopy and Electron Dispersive Spectroscopy (EDS) had demonstrated that the items had been immersed in a corrosive substance but could not determine specifically what the corrosive had been.¹

XPS is a surface analysis technique that permits both quantitative estimation of the elements present in a sample and determination of their oxidation state. Depth of information is only from the outer five to ten nanometres of the surface being analyzed. It operates by using a high-energy X-ray beam to excite electrons and etch a thin layer (approximately ten nanometres) of the sample surface. The number and kinetic energy of these electrons is measured and the machine produces a graph specific for the chemical and electronic state of each of the elements present. This study hypothesized that it would be capable of determining the specific chemical identity of the corrosive in this matter; specifically, finding evidence of Cl⁻ ions would be sufficient to permit this conclusion. No prior preparation of the surface was required.

One of the crowns was selected and an area of the crown was exposed to the X-ray beam in a hard vacuum. The kinetic energies of the resulting electrons were analyzed and charted by the machine.

This study was able to determine the elemental composition of the crown at the scanned location. It confirmed the makeup of the crown as first determined by EDS. Crucially, it also showed the presence of chlorine.

To test the hypothesis that chlorine would be found only in the surface (indicating immersion in HCl), an *in situ* argon ion gun was used to etch 20 nanometres of the surface from the sample and then the surface was re-analyzed. The comparison between the two scans confirmed the presence of the two peaks characteristic of chlorine, demonstrating its presence in the surface layer, probably as the chloride of nickel, molybdenum, or both. The post-etch analysis showed a greatly reduced level of chlorine, confirming the hypothesis that the chlorine was confined to the surface level only.

The presence of chlorine in the surface layer of the metal component of the dental crown, and the reduction in its level as the test moved more deeply into the metal, confirmed the hypothesis that the corrosive substance in which this crown had been immersed was Hydrochloric Acid (HCl).

This presentation provides information on the use of XPS to determine the surface composition of a dental crown believed to have been immersed in hydrochloric acid, and demonstrates that the technique can be used to demonstrate this fact. This analytical technique may be of relevance to forensic analysts who are required to make similar determinations.

Forensic Odontology, Analytical Technique, XPS

G3 Reassessing the Dental Features of Lamendin's Age-Estimation Method

Eleni Zorba, BS, University of Athens, School of Medicine, Dept of Forensic Medicine & Toxicology, 75 M Asias Street, Athens 11527, GREECE; Matteo Borrini, PhD*, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Konstantinos Moraitis, PhD, 75 M Asias Street, Athens 11527, GREECE

After attending this presentation, attendees will be more aware of each dental feature of Lamendin's method and its accuracy in age estimation. Repeatability, high accuracy, and high correlation with age are traits of a good age indicator.

This presentation will impact the forensic science community by helping forensic practitioners decide if the new equations derived only from certain dental features should be used for aging human remains.

Age estimation forms one of the most important steps in forensic anthropological analysis. Teeth, being very resistant to postmortem destruction and fragmentation, can be used as an alternative biological material for age estimation, especially when bones are not well preserved. Gustafson was the first to develop an aging method based on six features of dental structure.¹ Modifications of this method were later developed, including the technique of Lamendin et al.² The authors of this method established an equation for estimating age-at-death in adults based on the measurement of periodontosis (gingival regression) and root transparency height as related to the overall height of the root, taken from the labial surface of single-rooted teeth. The goal of the present study is to reassess the significance of these dental variables in estimating age-at-death using the canines from a modern European skeletal sample. A new equation for age estimation is derived for each canine using only the variables presenting significant correlation with age. The canines of 73 individuals (43 males and 30 females) from the Athens Collection were examined. This skeletal collection consists of individuals of known sex, age, occupation, and cause-of-death that died in the second half of the 20th century in Athens, Greece. The mean age was 46.02 years (range: 24-96 years) and 48.30 years (range: 20-85 years) for males and females, respectively. Periodontosis, root transparency, and maximum root height were measured at the mesial, distal, labial, and lingual surface of each canine, using a digital sliding caliper. Pearson's rank correlation statistics were applied to identify relationships between each measurement taken and chronological age. Multiple Regression Analysis (MRA) was applied in correlation with age variables in order to produce the best predictive model for age estimation. In addition, bias and inaccuracy tests as well as a Wilcoxon test were performed to assess the accuracy of the method. Age was estimated using the prediction equation for each canine. Only periodontosis and root transparency presented a statistically significant positive correlation with age. MRA produced four different models for each canine with R² ranging from 67.6% to 79.2%. Bias results showed that there was a small overestimation of one to two years for ages 20-59 years old; however, in ages more than 60 years, there was an underestimation that reached 17 years. The Wilcoxon test showed a significant difference between estimated and real age only for individuals over 60 years of age.

In conclusion, periodontosis and root transparency are robust age indicators as they present a high correlation with age. The new regression equations were found to be suitable for an accurate age estimation with the most accurate results to be observed among individuals 20-59 years of age. The low values of mean error (bias) from the real age make canines reliable for estimating age-at-death using only the dental features of periodontosis and root transparency.

Forensic Odontology, Forensic Anthropology, Age Estimation

G4 Evolution of Forensic Odontology Services in Queensland: 1994-2014

Alistair Soon, BDS, Forensic and Scientific Services, Forensic Odontology/Pathology Unit, 39 Kessels Road, Coopers Plains, Queensland 4108, AUSTRALIA; Alexander S. Forrest, MDS*, Griffith University Nathan Campus, School of Natural Sciences, Griffith Sciences, 170 Kessels Road, Nathan, Queensland 4111, AUSTRALIA; Henry Y.H. Wu, Forensic and Scientific Services, Forensic Odontology/Forensic Pathology Unit, Coopers Plains, Brisbane, Queensland 4113, AUSTRALIA; Bradley D. Ross, BDS, Forensic and Scientific Services, Forensic Odontology/Pathology Unit, 39 Kessels Road, Coopers Plains, Queensland 4108, AUSTRALIA; and Annu Nangia, MDS, Forensic and Scientific Services, Forensic Odontology/Pathology Unit, 39 Kessels Road, Coopers Plains, Queensland 4108, AUSTRALIA*

After attending this presentation, attendees will be able to evaluate the evolving pattern of casework undertaken over a 20-year period at the Forensic Odontology Unit, Forensic and Scientific Services (FSS), Department of Health Queensland Government in the state of Queensland, Australia. The single largest change in the pattern of practice has resulted from the introduction of a Toshiba® Aquilion™ 16-Slice Computed Tomography (MSCT) scanner in 2009. It will also be clear that increasing recognition by forensic pathologists of the role forensic odontologists can play in the investigation of facial and dental trauma has led to a change in the types of casework forensic odontologists undertake. An increasing recognition of the expertise possessed by forensic odontologists has also led to increased consultation in cases where oro-dental pathology may have contributed to the cause of death.

This presentation will impact the forensic science community by showing the changing nature of the caseload in forensic odontology in Queensland, Australia, and underlines the importance of incorporating CT technology in forensic odontology casework.

FSS is a large organization that exists under Health Support Queensland (Department of Health Queensland Government) to provide expert analysis, advice, and research in forensic matters including forensic molecular biology, forensic chemistry and toxicology, and forensic pathology and odontology. It is tasked with supporting a Queensland Government response to threats to public health and the environment, epidemics, civil emergencies, criminal investigations, and coroners' inquiries into reportable deaths. The Forensic Odontology Unit is part of the Forensic Pathology Department in FSS.

The Forensic Odontology unit at FSS deals with only coronial cases. These include routine coronial identification and dental age estimation, as well as assisting in coronial death investigations by consultation with forensic pathologists. Examination of submitted items is also undertaken when this is requested by the Queensland Police Service (QPS) or from other departments within the Department of Health Queensland Government, such as the Environment and Food Testing section.

In the 1990s, postmortem dental identification routinely involved resection of both the maxilla and mandible. Accomplishing this important work and recognizing that avoiding mutilation out of respect for the deceased is a guiding principle in all undertaken work. Consequently, this study has adapted techniques to utilize imaging and image comparison wherever feasible to negate the need for jaw removal. This has been very successful — today, if jaw resection is required, permission needs to be sought and strongly justified in writing from the Queensland State Coroner, and degloving techniques are used to ensure that the replaced bony and soft facial tissues look undisturbed at the end of the examination. Statistics show that since the end of 2006, only two jaw resections have been required for access to the dentition. While the MSCT has been extremely useful in obviating the need to perform resections, this was being achieved some years prior to its introduction at FSS, reflecting this study's underlying philosophy.

Since 2009, the MSCT has been used to provide 3D image data of all forensic cases admitted to the FSS. This data can be sliced and reconstructed (Multi-Planar Reconstruction (MPR) imaging) to simulate plain-film radiographs including orthopantomograms. These MPRs are useful in comparing the features of the postmortem dentition with available antemortem dental records and radiographs. It also plays a role in disaster victim identification responses for both dental identification and age estimation in children and adolescents. CT data can also be used for assessing injuries in the maxillofacial region when assessment and comment on injuries and injury patterns are required or requested.

Forensic Odontology, Computed Tomography, Forensic Services

G5 Forensic Dentistry and Malpractice Lawsuits in Turkey

Huseyin Afsin, PhD, Hacikadin Caddesi 18-1, Kocamustafapasa, Istanbul 3400, TURKEY; Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; Beytullah Karadayi, PhD, Istanbul, TURKEY; and Abdi Ozaslan, Istanbul University, Cerrahpasa Tıp Fakültesi Adli Tıp Anabilim Dalı, Istanbul, Fatih 34098, TURKEY*

After attending this presentation, attendees will be familiar with Turkish malpractice laws, cases that have been brought against dentists, and general statistical data about dentistry in Turkey.

This presentation will impact the forensic science community by presenting a history of forensic dentistry in Turkey.

The 2012 census shows the population of Turkey to be 75,627,384 with 24,725 practicing dentists. This gives a ratio of 27 dentists per every 100,000 Turkish citizens. Dentists complete their education in a five-year curriculum in one of the 55 universities which offer the course. Article 10, document number 1219 of Turkish law forbids foreigners from practicing medicine in Turkey; however, with recent changes to the law, if they meet standards set forth by the law, their practice in dentistry is lawful. The Ministry of Health's data shows that 89.3% of individuals between the ages of 35 and 44 years had at least one tooth missing and there were seven million fillings performed by dentists working for the ministry.

The number of malpractice lawsuits is on the rise in Turkey. Some of the reasons for this increase include an increase in the number of people seeking medical services, higher patient expectations, media obsession with these cases, and the fact that some attorneys solicit and recruit patients for filing malpractice lawsuits.

Below are two Turkish Penal laws as they are written in the statutes:

Reckless Homicide Article 85: the punishment of an individual who commits reckless homicide will be imprisonment for two to six years.

Willful Injury Article 86: (1) the punishment of an individual who causes pain or detriment to someone's health or ability to function normally will be imprisonment for one to three years; and, (2) provided that the willful injury has a mild effect on the victim's health and well-being and can be remedied by a simple medical intervention, the perpetrator is punished with imprisonment of four months or a judicial fine.

Patient confidentiality and obtaining consent for treatment are the dentist's responsibilities. Some of the cases brought against dentists in respect to these areas include: forcing the patient to give consent; medical intervention of an incapacitated person without consent of their guardian, curator, or the court; asking the patient to sign a blank piece of paper or write, "I accept any intervention;" and, so forth. As for malpractice cases against dentists in Turkey, reasons for these lawsuits include not meeting medical standards due to lack of knowledge or neglect and medical device malfunction. According to a review of judicial files, there were 101 malpractice lawsuits filed against dentists between 1984 and 2008: 44% of the cases were for faulty dentures; 29% for wrongful surgery; 9% for wrongful orthodontic treatment; 8% for faulty implants; 5% for wrongful periodontal treatment; and, 5% for other dental treatments.

Forensic Dentistry, Malpractice, Turkey

G6 What You See Is Not Always What You Should Believe: A Presentation of the Inconsistencies Commonly Seen in Antemortem Dental Charting

Marnie L. Sperling, DMD*, 199 Pierce Street, Apt 822, Somerset, NJ 08873

After attending this presentation, attendees will gain understanding of antemortem dental charting practices and the inconsistencies, both intentional and unintentional, by a treating dentist as well as the potential negative effects on the dental identification process of the deceased.¹

This presentation will impact the forensic science community by providing examples of how charting inconsistencies, whether intentional or unintentional, can have significant effects on the human identification of dental remains by forensic dentists. This presentation will also strive to broaden the understanding of the importance of a systematic means to document and interpret dental charting in cases where a dental identification is necessary and will emphasize and enable an increased awareness that documentation inconsistencies can occur, demonstrating some of the most common charting inconsistencies according to the literature.

According to Zahrani, dental identification has become a vital resource for identification of human remains of mass disasters, acts of terrorism, severe mutilation, or burning of bodies. The identification of human remains has become essential for both legal and humanitarian issues.²

The human dentitions' uniqueness is what makes it such a benefit for identification purposes; the dentitions can also be so unique that charting a patient's dentition can make patient dental charting in the antemortem setting a somewhat subjective task to even the most scientific of dental practitioners. Such charting dilemmas can evolve as a result of irregular tooth development, shifting of dentitions, adaptive changes, and restorative work done by previous practitioners.

Problems in human dental identification frequently involve the lack of adequate dental charting, as some practitioners do not chart existing restorations but only chart work to be done or work that was completed. As the medical field is gradually moving to electronic health records, many dental practitioners still utilize handwritten records. Radiographic imaging is also a factor in regard to the antemortem dental records. Some patients may limit the amount of or even refuse to have radiographs taken. Some radiographs are taken with poor angling techniques or, in some cases, could be mounted or moved digitally to an improper position on the mounts or templates. The other major factor is human error. Human errors can cause significant inconsistencies in comparison analysis for dental identifications.

The problems and possible inconsistencies that will be identified in this presentation can result in delaying for many hours or possibly even days a positive identification of the deceased in order to provide a grieving family closure of a loved one's death.

G7 Analysis of Human Bitemarks in Food and Beverages Using Metric and Biological Analysis

Ricardo H.A. Silva, PhD*, USP-School of Dentistry of Ribeirao Preto, Avenida do Cafe, s/n, Bairro Monte Alegre, Ribeirao Preto, Sao Paulo 14040-904, BRAZIL; Lais G. Araujo, MSc, USP - School of Dentistry of Ribeirao Preto, Avenida do Cafe, s/n, Ribeirao Preto 14040-904, BRAZIL; Aline Azevedo, PhD, USP - School of Dentistry of Ribeirao Preto, Avenida do Cafe, s/n, Ribeirao Preto 14040-904, BRAZIL; Raquel F. Gerlach, PhD, USP - School of Dentistry of Ribeirao Preto, Avenida do Cafe, s/n, Ribeirao Preto 14040-904, BRAZIL; Adriana A. Marques, MSc, USP - Ribeirao Preto Blood Center, Tenente Catão Roxo, 2501, Ribeirao Preto 14051140, BRAZIL; Wilson A. Silva-Junior, PhD, USP - Ribeirão Preto Medical School, Avenida Bandeirantes, 3900, Ribeirao Preto 14040-904, BRAZIL; and Rodrigo Galo, PhD, UNESP - Araraquara Dental School, Rua Humaita, 1680, Araraquara 14801-903, BRAZIL

After attending this presentation, attendees will understand the importance of analyzing bitemarks by both physical and biological methods in criminal cases involving forensic odontology.

This presentation will impact the forensic science community by presenting different tests which will achieve human identification in simulated cases involving bitemarks and evidence found at crime scenes.

Multiple methods can be used for the comparison analysis of a suspect dentition to a suspected bitemark injury. The two most common are metric or biological analysis. Metric analysis involves the overlaying of a replica suspect's dentition above the pattern injury. This can be done physically, via caliper measurements, or virtually, using computer software. Biological analysis involves the comparison of the deposited salivary cell's DNA with a reference sample; however, the effectiveness of these methods can vary greatly depending on the impression substrate.

Study Goal: The goal of this study is to compare the effectiveness of four metric analysis methods on bitemarks produced in cheese and chocolate. A second goal was to determine if a biological method using DNA extracted from the saliva residue left on bitten food or water consumed from a bottle could also be used for comparison. Additional variables, such as the storage temperature of the substrate following the biting, as well as the time interval between the time of biting and time of analysis would have an effect on the analysis.

Study Design: The study consisted of 20 volunteers, ten males and ten females. The subjects were asked to bite into five samples of soft cheese, five samples of chocolate, and to drink from five bottles of water. This produced 15 samples from each of the 20 participants. One sample of each type was analyzed immediately while the remaining were stored at either room temperature (25°C) or in a refrigerator (4-8°C). Those samples were later divided so that one set was analyzed at three days and the other at seven days. Impressions were made of the bitten foods as well as the maxilla and mandible of all the participants utilizing alginate. Plaster casts were fabricated from all the impressions. Finally, reference DNA sample were obtained from each subject by collecting 2mL of saliva *in natura*.

Analysis: Four different metric analyses were performed on the food, one using a digital caliper, one using a manual overlay of the dental casts opposing the casts of foods, and two using a digital imaging overlay method and Adobe® Photoshop®. Metric comparisons were performed by a single forensic odontologist. For the biological analysis, a sample of the DNA was collected from cheese, chocolate, and water using the double-swab technique. The DNA was extracted according to the protocol of the QIAGEN® QIAamp® kit, quantification of the recovered DNA was performed using a NanoDrop™ spectrophotometer. Amplification was then performed using Identifiler® PCR Amplification AmpFISTR® kit (CSF1P0, D2S1338, D3S1358, D5S818, D7S820, D8S1179, D13S317, D16S539, D18S51, D19S433, D21S11, FGA, TH01, TPOX, VWA, and amelogenin) and agarose gel electrophoresis.

Results: The results showed that there was no significant difference between the four metric methods used. Manual overlay comparison yielded the highest number of matched subjects with 58% for both sexes. The Adobe® Photoshop® method yielded the lowest number with only 32% of the female samples matching and 44% of the males. For the biological analysis, DNA samples from saliva deposited in water, cheese, and chocolate had concentration values ranging from 26.66±12.32 to 9.38±3.42, showing that there was sufficient DNA present for amplification and later comparison. Thus, it was concluded that the sampling of food products at crime scenes can be important to investigators in identifying a suspect by utilizing metric and biological analysis.

Bitemarks, DNA, Saliva

G8 How the Characteristics of One Tooth Were Used to Make a Dental Identification in a Burn Victim: A Case Report

Xiomara N. Rivera, DMD, Urb University Gardens, 251 Fordham, San Juan, PR 00927*

The goal of this presentation is to show how the characteristics of a single tooth were used to help make a positive dental identification of the partial remains of a burn victim.

This presentation will impact the forensic science community by sharing an interesting case where a partial maxilla and seven teeth were the only oral structures found on charred remains and by discussing how a single tooth's characteristics and dental treatment helped make a positive identification of the body. Other single tooth dental identifications have been reported by the forensic dentistry community and it has been noted that said tooth should possess a quality that would set it apart from others, thus eliminating the possibility of a misidentification.

A burned body was discovered at a beach in Puerto Rico inside the trunk of a burned car. The personnel from the Institute of Forensic Sciences of Puerto Rico were called to the scene and recovered the charred remains. These were believed to be the remains of a young man who had recently been reported missing. Using the car's license plate, the car was traced to a family member of this young man, thus reaffirming the possibility of the remains belonging to this person. An interview with the family of the presumed deceased provided the name of the dentist who treated this person. Personnel from the Institute of Forensic Sciences in Puerto Rico requested the dental record and radiographs from the dentist.

Upon examination, the remains were found to be mostly broken down into small, very burned pieces. The anterior part of the maxilla was found in two pieces with some teeth still in their sockets. Other teeth, including three maxillary molars whose crowns were observed to be partially destroyed by the fire, were found in the remains. Digital radiographs, using a hand-held X-ray machine, were taken of these oral structures. A dental autopsy was performed. The antemortem and postmortem radiographs and dental information were compared. Only one tooth, #11 (using the universal numbering system), was found to be in both sets of radiographs and have enough structure left to make a comparison. Antemortem radiographs showed that a root canal treatment had been performed by the dentist. They also revealed a root dilaceration. Both of these notable features provided comparison data, leading to the conclusion that the anatomy and dental treatment performed on this one tooth should lead to a positive identification of the victim.

Dental Identification, Single Tooth, Puerto Rico

G9 Methodology and Interests of 3D Modeling of Bitemarks

*Charles E. Georget, PhD**, 5 Rue Voltaire, Amboise 37400, FRANCE; *Aime Conigliaro, MA*, Fort de Rosny, 1 boulevard Théophile Sueur, Rosny sous-bois 93110, FRANCE; and *Francois Duret, DDS, PhD*, Chateau De Taraihan, Fleury D'aude 11560, FRANCE

After attending this presentation, attendees will understand the methodology used and the interests of the optical impression of the bitemarks on a victim's skin and on the dental arches of the suspects. This technology offers a color 3D view of injured tissue and teeth and allows the backup of all data later submitted for analysis.

This presentation will impact the forensic science community by explaining how this new protocol and advanced technology will make experts aware that the recording of the shapes of bitemarks and the development of their features can be achieved in good condition either at the crime scene before any manipulation of the body or at the forensic medical institute with no risk of image distortion (poor angle of the photographic view taken) or skin deformation by overload stemming from the application of a conventional impression material (alginate, silicone). This protocol, which was laboratory tested, can be used for expert bitemark analysis.

As long as the protocol of modeling of the dental arches in 3D exists, the use of optical imprint technology is enough to reproduce the real shape of bitten human skin.

Material: The material used for the modeling of the 3D dental arches and for the modeling of injured tissues is unique. A laptop is necessary and works well to gather real-time 3D image analysis, reconstruction, and data storage software programs. An optical camera linked to the laptop by a USB port provides for the taking of impressions.

Method: All the tests carried out check that the imprint of the bitemarks on the victim and the imprint of the dental arches of the suspects are automatically made in the same scale. Repetitive results are also verified, thus allowing the superimposition of teeth and bitemarks without any risk of unmanaged enlargement. Moreover, modeling and image processing must allow for the 3D superposition of bitemarks and of the dental arches. The color of the lesions are verified, as well as that the teeth are of optimal quality, and that the measurement tools available meet the specific needs and are reliable. This is the process for cuts made on teeth before being superimposed on bitemarks.

Conclusion: Dental computer-aided design/computer-aided manufacturing used in forensic dentistry provides reliability in the study of bitemarks. It avoids the errors related to the photographic shots at a bad angle and the consequent change of data. The 2D image replaced by a 3D image becomes a concrete support and the superposition of the teeth and bitemarks provides a more accurate analysis. The latter, presented to a magistrate, will facilitate the comprehension of the bite process.

Dental CFAO, Bitemarks, Postmortem

Odontology Section - 2015

G10 Bitemarks From the Emergency Room to the Courtroom: The Importance of the Expert in Forensic Odontology

*Franklin D. Wright, DMD**, 1055 Nimitzview Drive, Cincinnati, OH 45230; and *Melissa Mourges, JD**, New York County District Attorney's Office, One Hogan Place, New York, NY 10013

After attending this presentation, attendees will be aware of how forensic odontology plays a vital role in many arenas, especially when crimes against children are involved. By identifying victims of child abuse as well as their abusers, forensic odontologists provide valuable services at every phase of the criminal justice process.

This presentation will impact the forensic science community by communicating how, through forensic case examples and legal case citations, forensic odontology aids in the detection, prevention, and prosecution of child abuse and other serious crimes.

Lost in the debate over bitemark testimony is the undeniable fact that forensic odontologists provide vital information at every phase of a criminal investigation and prosecution. This is especially true for cases involving society's most vulnerable victims, the children who are all too frequently abused in the unwitnessed privacy of their homes by their own caregivers.

Case examples will demonstrate the importance of fast response by a well-trained forensic odontologist to a pediatric Emergency Room (ER) or more tragically, the morgue, where evidence of both old and new bites and other abuse may be visible. Forensic odontologists can examine suspected bitemarks and determine whether they are human or animal or not bitemarks at all.

The ability to quickly include or exclude a suspected biter, or to reliably identify a biter, especially in the closed population of a family or daycare group, is of vital importance. Sometimes, the "usual suspect," who is often the mother's boyfriend or other adult male in a household, might be charged and jailed, or at a minimum, barred from the home during the investigation. A timely examination, analysis, and comparison can determine that the culprit is actually a child who might be large for his age. Once the bite is recognized as non-criminal, the initial suspect is exonerated. Similarly, when a child in the ER with human bites comes under the care of a forensic odontologist and the perpetrator is identified as the mother, the victim and other children in the household can be removed from the specter of further harm.

While critics of bitemark testimony cite the 2009 National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward*, as authority for keeping forensic odontologists out of the courtroom, federal and state court judges reject that approach. A survey of both federal and state court opinions confirms that courts have not read the NAS Report as authority to scuttle long-accepted forms of forensic evidence, including forensic odontology. Judges, especially at the trial level, appreciate the value well-trained and careful forensic odontologists bring to the fact-finding process.

Just like fingerprint analysts who can match a latent to an inked print, a forensic pathologist who can determine cause and manner of death, or a forensic psychiatrist who retroactively evaluates a defendant's state of mind at the time of a past crime, forensic odontologists bring crucial expertise into a courtroom. A jury faced with 8"x10" color photos of a child grievously injured with bitemarks and the daunting responsibility of determining whether the charged defendant inflicted them, deserves every item the criminal justice toolbox has to offer.

Forensic Odontology, Criminal Justice, NAS Report

G11 An Objective, Dynamic Bitemark Overlay Technique

Alexander S. Forrest, MDS, Griffith University Nathan Campus, School of Natural Sciences, Griffith Sciences, 170 Kessels Road, Nathan, Queensland 4111, AUSTRALIA; Chris Little, BS, Griffith University, School of Engineering, Parklands Drive, Southport 4215, AUSTRALIA; and Alistair Soon, BDS, Forensic and Scientific Services, Forensic Odontology/Pathology Unit, 39 Kessels Road, Coopers Plains, Queensland 4108, AUSTRALIA*

After attending this presentation, attendees will be informed about a method of producing bitemark overlays that are objective, reproducible, and aid in the analysis of the 3D interaction between a dentition and a bitten surface. Attendees will understand the principles behind the overlay's creation and use.

This presentation will impact the forensic science community by demonstrating how many of the complexities inherent in the production and imaging of traditional bitemark overlays can be addressed and will understand how to make and work with objective overlays that eliminate imaging problems and subjective decisions. Attendees will also understand how these overlays can be used to build a 3D appreciation of the interaction between a dentition and a bitten surface.

Bitemark templates or overlays (also known as “exemplars”) are traditionally considered to comprise outlines of incisal edges of teeth used in the comparison process. The use of only the incisal edge outlines ignores the mechanics of the wide biting process and fails to document the palatal anatomy of the upper incisor teeth. Further, many of the techniques used to produce them have been shown to be subjective, introducing a potentially uncontrolled source of error to an already error-prone process.

This presentation seeks to address the subjective elements of overlay production and additionally creates a series of contour slices through a model that can be used to examine the 3D interaction between a dentition and a bitten surface.

Initially, an accurately cast dental model of a dentition to be compared with an alleged bitemark injury is obtained and a digital model of it is produced by rendering isosurfaces from a high-resolution laser scan of the model. Laser scanners with a resolution of 20 microns or better are becoming increasingly common in dental offices and laboratories and a typical scanner will produce a model of a dental cast in approximately 75 seconds.

The mean angle of the occlusal plane to the substrate at the time of biting is estimated and the occlusal plane of the virtual model is positioned accordingly to the horizontal. If the plane is not evident, then two comparisons are suggested, one with a horizontal occlusal plane and one with the maximum estimated angle to the bitten surface. Both are used, and it is said that the true angle lies somewhere between these extremes.

The digital model can then be cut into virtual slices at whatever interval is deemed appropriate, commonly 0.5 millimeters. Each slice can be rendered as a 3D structure or as an outline drawn around the bottom of the slice. Each of these slices represents the tooth surface at the relevant distance from the occlusal plane and can be used separately or assembled in any combination to examine the 3D interaction between the injury and the overlay, addressing the “dynamic” aspect of the technique.

When different individuals are provided with the scan resolution and the original cast (or an accurate copy) and they agree on the position of the occlusal plane and the slice interval, they will end up with the same result, addressing the objective aspect of the technique. The rendering of outlines from the base of each slice creates objective hollow-volume contour overlays that can be reproduced by different operators.

When the successive slices are used, either in sequence or assembled, comparison with impressions or marks resulting from contact between the substrate and the palatal surfaces of upper incisors and marks resulting from dragging of the dental arch across the bitten surface becomes possible, often increasing the number of characteristics that can be used for comparison.

The technique is illustrated and its application in reducing uncontrolled errors in overlay production phase of the bitemark comparison process is demonstrated.

Forensic Odontology, Bitemark, Bitemark Overlay

G12 Bitemark Evidence

Robert B.J. Dorion, DDS, Laboratoire S.J.M.L., Edifice Wilfrid-Derome, 1701 Parthenais, 12ieme, Montreal, PQ H2K 3S7, CANADA*

After attending this presentation, attendees involved in bitemark analysis will better understand distortion of bitemarks resulting from infliction on different parts of the porcine anatomy.

This presentation will impact the forensic science community by making the attendee aware of the various potential problems involved in human bitemark interpretation, analysis, and comparison with suspect dentitions.

In vivo porcine skin is considered as a representative model for the study of human bitemarks.¹⁻⁵ Error rates have also been calculated using the porcine skin model as a substitute for human skin.⁶ The current study compares 20 bitemarks inflicted by the same dentition (known biter) on different parts of the porcine anatomy. The bite sites include the neck, the thorax, the axilla, the thigh, the stomach, and the back.

The type of photographs studied were color and alternate light imaging and all were lens and metrically corrected prior to comparison. The photographs were taken *in vivo* at the time of bitemark infliction and on the third day postmortem. The latter scenario was chosen to mimic a potential real-life encounter of a Friday body recovery with a Monday autopsy. Participants will have an exclusive and rare opportunity to observe the amount of change in the bitemark pattern from antemortem infliction to postmortem observation on the third day. The upper and the lower arches of the bitemark were compared separately and serially. The same exercise was performed comparing the bitemarks to the dentition that created them.

Conclusions will be drawn from this exercise in order to minimize potential difficulties of interpretation, analysis, and comparison with a potential suspect dentition in a human.

Forensic Odontology, Bitemark, Dentition

G13 Paradigm Shifts on the Validity of Bitemark Evidence and the Dramatic Connection With Best Practices in Forensic Technical Analysis Via the Poma Murder in Rome: A Case Report

Emilio Nuzzolese, PhD, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari 70124, ITALY*

After attending this presentation, attendees will have an understanding of the Italian judicial penal system and the appointing of expert witnesses in court.

This presentation will impact the forensic science community by highlighting the importance of specialist training in forensic science and medicolegal doctrines for dentists before involvement in any lawsuits.

Medicolegal evaluation in civil and penal cases of dental and/or odontology case works require expert witnesses with biological and technical knowledge of dentistry and a sound medicolegal education and experience. During the 2013 International Organization of Forensic Odonto-Stomatology international congress in Florence, Italy, the civil law judicial system on the designation of expert witnesses in six states were investigated, highlighting the need to work toward harmonization with more rigorous standards to become eligible as an expert witness in court, preventing spontaneous involvement of dental practitioners, and to improve their forensic and law teaching. These issues are even more relevant to penal case works.

In this presentation, a 20-year-old homicide cold case with a pattern injury suggestive of partial bitemark evidence is presented. Raniero Busco was accused of having murdered Simonetta Cesaroni, his ex-girlfriend, on Via Poma in Rome in 1990. A pattern injury on the breast of the victim was assessed as a “bitemark” by the forensic pathologist performing the autopsy. After 18 years, the case was reopened for new DNA analysis and the pictures of the “bitemark” on the breast were re-evaluated by dentists, pathologists, and odontologists. The injury suggestive of a partial bitemark is presented, demonstrating the concerns around the paradigm shifts on the validity of bitemark evidence and the dramatic connection with the technical analysis which is applied. The Italian judicial penal system and the analysis of the expert witnesses are presented. Questions and concerns on quality assurance and the criteria of forensic analysis of patterned injury are raised. Raniero Busco was found guilty in the first trial in 2011 and sentenced to 24 years in jail; he was subsequently acquitted on appeal in 2012. The acquittal of the accused was confirmed by the Supreme Court in 2014, which turned down the appeal by the Attorney General.

The purpose of this presentation is to promote a discussion within the dental community about who should perform forensic analyses in order to reduce errors and observer bias. The responsibility of forensic experts is to emphasize to colleagues who want to work within the judicial systems that forensic cases must follow precise legal, ethical, and scientific rules, which go beyond everyday dentistry and training. Pitfalls and errors can lead to erroneous attribution of responsibilities in professional liability cases and faulty accusations of innocent people. Dentists without specialist training should refrain from involving themselves in such lawsuits, leaving expert witness testimony to those dentists qualified in forensic sciences and medicolegal doctrines.

Bitemark Analysis, Forensic Odontology, Expert Testimony

G14 Construct Validity of Bitemark Assessments Using the ABFO Bitemark Decision Tree

Adam J. Freeman, DDS, 22 Imperial Avenue, Westport, CT 06880; and Iain A. Pretty, DDS, PhD, Dental Health Unit, Williams House, Lloyd Street, N, Manchester Science Park, Manchester M15 6SE, UNITED KINGDOM*

The goals of this presentation are to help attendees understand both the nature of agreement with respect to decision making and the importance of construct validity in the assessment of bitemarks.

This presentation will impact the forensic science community by informing attendees that bitemarks are currently under considerable scrutiny from judicial and scientific communities and by providing the result of an assessment of 100 injuries to determine the degree of agreement.

Since the criticisms within the 2009 National Academy of Sciences Report, Strengthening Forensic Science in the United States: A Path Forward, bitemarks have been an area of odontological practice that continue to be under considerable scrutiny.

The American Board of Forensic Odontology (ABFO) has developed a decision tree to help odontologists navigate the assessment, analysis, and conclusion levels that should be applied to bitemarks. The first portion of the decision tree is to assess a patterned injury to determine if it is a bitemark, suggestive of a bitemark, or if biting can be excluded as a cause. If the injury is determined to be a bitemark, then the next step is to determine if individual arches and tooth marks are identifiable within the injury. Following this, the decision tree goes on to assess the analysis and comparison of the injury.

This research study was concerned with the first two stages of the pathway — if these are not reliable or valid then the rest of the decision tree is rendered invalid. In order to assess the level of agreement using the decision tree, the following was undertaken: 100 injuries, comprised of suspect bitemarks and other patterned injuries, were presented, using a web-based system, to ABFO diplomates. Each image set included at least one scaled and one orientation image. No contextual information was provided. Respondents were asked to rate each image as either a bitemark, suggestive of a bitemark, or not a human bitemark. For those responses where the injury was determined to be a bitemark, an additional question was asked concerning the identification of individual arches and tooth marks.

In total, 39 diplomates completed all 100 questions out of 103 diplomates contacted. As there is no established reference standard for these data, a modal approach was adopted with percentage agreement established between the respondents. Data will be presented on the each of the decision elements, including the dichotomous decision to render an opinion, the three options for stating if the injury was a bitemark, and the level of forensic significance associated with the injury.

Bitemark, Agreement, Reliability

G15 Bitemarks: To Profile or Not to Profile — So What's the Question?

Richard R. Souviron, DDS, 336 Alhambra Circle, Coral Gables, FL 33134*

After attending this presentation, attendees will know the value and importance of profiling as a part of the initial phase of bitemark analysis. The significant differences with actual case material versus experimental bites on cadavers and live volunteers will be shown and explained.

This presentation will impact the forensic science community by sharing the experience of profiling bitemarks in experimental cases and comparing them with actual case material. The importance of analyzing a bite pattern and forming a profile of the biter may be necessary to obtain a court order or search warrant in order to proceed with securing records from a defendant. The bitemark profile will provide the necessary “probable cause” to justify a search warrant or court order.

A bitemark left in human flesh by another human will not only leave a pattern injury but, most importantly, DNA evidence. The forensic odontologist will be responsible for first analyzing the injury, then providing an opinion as to the origin, such as human or animal teeth or a pattern that mimics a bitemark. If the injury is indeed a bitemark left by human teeth, the investigator should be able to classify the bitemark based on its appearance and detail or lack of detail.^{1,3}

A Class I bite exhibits no details of individual teeth and has been described as a “smoky ring,” but it still is of evidentiary value. It may yield DNA evidence and may be helpful in the elimination of suspects. A Class II bite pattern will have class characteristics but limited individual tooth pattern recognition and may have only one arch identifiable. A Class III bite pattern has been referred to as a “classic” bitemark. Both arches are present and individual teeth can be identified. A Class IV bite is one that produces total avulsion of the body part such as an ear, finger, or nose and usually does not leave a Class or individual pattern. There may be another area of the body with a Class I, II, or III bite pattern.^{1,4}

The analysis of a bitemark should include an opinion as to the arrangement of the biter's teeth, the position of the biter vis-à-vis the victim and, in some cases, whether the bite was left by a child (deciduous teeth) or an adult. This is all part of the analysis of a bitemark and specifically profiling of a bite with real teeth in a real (not experimental) situation will be helpful to the authorities and indeed may be essential in order to obtain a search warrant or court order.^{1,2,4} A bite profile need not be very specific and should leave room for modifications. An example is a bite that shows a space between the maxillary incisors or where the pattern shows clearly crooked teeth. Distortion plays a part in almost all bitemarks and needs to be taken into consideration. Profiling may be possible with all classes of bites except the Class IV. Profiling with experimental bites in cadavers is usually not possible, largely because of the distortion factor. Indeed, false profiles and mismatches are the usual result. Likewise, experimental bites on live volunteers after only a short period of time leave no pattern for profiling. This presentation will show profiling with all three classes of bites in real life cases, the effect of distortion on the bite pattern, and a comparison with experimental cadaver and volunteer bitemarks.

Bitemarks, Analysis, Profiling

G16 Lip Prints: Inter-Rater Reliability

Winnie Furnari, MS*, 82 Onondaga Street, Yonkers, NY 10704

After attending this presentation, attendees will recognize the similarities and differences in lip print analysis and appreciate the need for rater calibration methods for reliability.

This presentation will impact the forensic science community by demonstrating the error rate in an inter-rater reliability test for the analysis of lip prints.

Lip prints and their study, cheiloscropy, have been the topic of research and are also occasionally mentioned in literature by a detective, a crime scene investigator, or an examiner in another field of evidence comparison.¹ Subject comparisons have been recorded in the thousands. Research studies on lip prints have been contributed mainly by forensic dentists and anthropologists in countries throughout the world.

Literature and studies claim the uniqueness of human lip prints.^{2,3} Investigations may be able to rely on lip prints to identify possible suspects or to support evidence gained in investigations. A standard and uniform procedure has been put forth for the analysis of lip prints. The need to develop one cohesive cheiloscropy system, practicable in forensic dentistry, has been published as the one defined by Tsuchihashi in 1970.^{4,5} This method is published in the 2013 American National Standards Institute/National Institute of Standards and Technology (ANSI/NIST) revised dental standard ITL-1-2011.⁶

The legal community demands a reliable method of analysis and reliable experts to interpret patterns. This study sought to identify the amount of inconsistencies regarding the practice of lip print analysis, the results of which would determine the need for rater calibration. To prove the evidential value of lip prints in a court of law, a standard and uniform procedure has to be developed for the collection, development, and recording of lip prints and the ensuing comparison. The practice of analyzing lip prints is in the infant stage. Forensic odontologists are novice at it and have very little, if any, experience in the practice. Dentists with other forensic experience analyzed sets of lip prints using lip photos and prints recorded on paper. The results reveal the need for practice, experience, and further research to gain a status of reliability in the forensic community.

Many conclusions can be questioned when critical appraisal skills are applied, as in the calibration of examiners and also the inconsistency of methodologies in recording and analyzing prints. Establishing that the metric can be used consistently and reliably is attempted in this study. A consensus of uniqueness of lip prints must be reflected in the quality of the research and the number of prints analyzed to contribute to determining uniqueness. In addition to this study, more quality-designed studies using forensic professionals in the analysis of lip prints are needed. This further research of lip prints analysis should continue with the goals of meeting the *Daubert* standard and validating its usefulness in forensic identification for applicable legal matters.

Lip Prints, Cheiloscropy, Inter-Rater Reliability

G17 Morphological Patterns of Melanoderm Lip Prints In Dakar, Senegal

Khalifa Dieng, DDS, BP6602 Dakar Etoile, Dakar 8622, SENEGAL*

After attending this presentation, attendees will be educated on a variety of lip prints among the native Senegal population and the differentiation of lip prints for identification purposes.

This presentation will impact the forensic science community by describing a system which is seldom used but could be beneficial in the identification of unknown persons or suspects in criminal investigations.

In recent decades, the imprints of lips (cheiloscropy) attracted the attention of many scientists as a new tool for human identification in both civil and criminal matters. The present work was the in-depth study of lip impressions of men and women living in Senegal. A total of 200 people, including 96 men and 104 women, were included in the study. Red or black lip coloring and cellophane were used to print the lips. Each lip print was divided into six topographical areas and examined by magnifying lenses. They were then photographed and analyzed with greater magnification. Renaud classification in 1973 was used to classify the types of grooves and the results were analyzed statistically. Throughout the study, no identical lip print occurred in any two subjects. In total, impressions of lips (10.19% for both sexes) showed the same type of groove in all six areas of the lip (11.15% men and 12.56% women). It was found that 44.5% of lip prints (94 people) showed the same types of grooves in the Upper Right (UR) zone (46.88% men and 47.12% women); 45% (90 people) in the Upper Middle (UM) zone (52.08% men and 38.46% women); 52.5% (105 persons) in the Upper Left (UL) region (52.08% men and 52.88% women); 41% (82 people) in the Lower Right (LR) area (40.63% men and 41.35% women); 37.5% (75 people) in the Lower Middle (LM) zone (39.55% men and 35.58% women); 45.5% (91 people) in the Lower Left (LL) region (47.79% men and 46.15% women).

All ten types of grooves were recorded during this study. Groove type B (partial path from an edge, but not reaching the other side) was significantly more recorded (21.8%; 21.9% in men and 27.7% in women) followed by groove G (cross-linked forms) (21.3%; 21.2% in men and 27.4% in women); groove F (groove-shaped tree branch from an edge but not reaching the other side) (16.1%; 16.3% in men and 20.6% in women); groove D (fork or trident from an edge but not reaching the other side) (14.9%; 14.3 for men and 19.6% in women); groove A (complete path from one end to the other slot) (9.3%; 9.2% in men and 12.1% in women). The least observed grooves and I were in descending order (horizontal furrow or approaching the horizontal) (8%; 8.2% for men and 9.9% in women), followed by the groove J (ellipse, triangle, or V, while minor groove) (5.3%; 5.4% for men and 6.6% in women); H (intersection of groove sign of X or + sign) (1.8%; 2.5% for men and 1.6% in women); C (fork or trident from one side of the lip to the other) (0.8%; 0.7% for men and 0.8% among women), and groove E (shaped groove branch tree from one edge to the other of a lip) (0.7%; 0.4% in men and 1.1% in women). This study describes in detail the prints from the lips of melanoderm Senegalese men and women and seems to confirm that the “footprints” of lips are unique to each individual, even among twins and members of the same family. According to this finding, it is recommended that a database be set up for all individuals in the hope of being a reference in civil and criminal litigation. Further studies on a population with a larger effect on members of the same family and identical twins are recommended.

Lips, Print, Sengal

Odontology Section - 2015

G18 Honoring My Mentors — Drs. Levine, Snow, Maples, Stimson, and Stein

John P. Kenney, DDS, MS, 101 S Washington Street, Park Ridge, IL 60068-4290*

The goals of this presentation are to abide by Dr. Martell's meeting theme and to pay tribute to the forensic scientists who helped shape my 38-year career as a forensic odontologist.

This presentation will impact the forensic science community by stressing the importance of mentors and mentoring for all American Academy of Forensic Sciences (AAFS) members, not only in a specific section but also in the wider forensic community.

Beginning in October of 1976, I have had the good fortune to learn from and work alongside four of the most preeminent forensic scientists in the world: Drs. Lowell Levine, Clyde Snow, Bill Maples, and Robert Stein. Three of the four, most recently Dr. Snow, have passed away.

I first met Dr. Levine in 1976 at The Armed Forces Institute of Pathology (AFIP) while taking my first course as a "newbie" in the field of forensic dentistry. In May of 1979, I had just finished attending my second AFIP course, Aircraft Accident Investigation, and would return to Chicago from Washington, DC, on the night of May 24. The next day, the American Airlines DC 10 crash occurred. As one of the first forensic dentists on the scene, I was tasked by American Airlines to "find Dr. Levine" who had worked with American Airlines on an accident in the United States Virgin Islands a few years earlier. I had the good fortune to work alongside and learn from Dr. Levine in a major mass disaster when morgues had to be assembled from scratch, long prior to the current instantly operational Disaster Mortuary Operational Response Team system.

At the same disaster incident, I met Dr. Clyde Collins Snow, probably the original "Indiana Jones." Even in the midst of the chaos of a 273-person mass fatality incident, Clyde was a patient teacher of forensic anthropology. In the morgue at his table, he would carefully measure the bones that had been cleaned by the Chicago Police Department Homicide detectives. Clyde would explain in detail why and how he was doing his examinations. I even learned that it was possible to determine if a female had given birth based on the scarring of the pubic symphysis. We had a birthday party on Independence Day for Clyde, complete with a sheet cake and champagne, courtesy of Dr. Stein, the Chief Medical Examiner for Cook County. Unfortunately, July 4 was not Clyde's birthday. He entered his birthday into the American Airlines ID Database in European fashion, month-day-year, so actually he was born April 7, not July 4. He never let on until years later.

In 1984, I became the consultant odontologist for the Cook County Medical Examiner's office and Clyde, having worked both the Gacy case and the DC 10 crash, was the forensic anthropologist now used by the office. He would fly to Chicago each month and spend a few days on skeletal cases. I worked alongside him again on numerous cases when he came into town. He never stopped teaching, asking questions, and also learning some forensic odontology from me.

I met Bill Maples at AAFS meetings. My first real work with him was on the Forest Lawn cremation case. I was invited to a meeting at the Cook County Medical Examiner's Office to assist with the dental radiography of a metal dental post that was found in interred cremains and that became critical to the correct identification. Dr. Maples was the lead anthropologist on the case. I would work another cremains case in Chicago with him and testify for the defense with him on a third case.

The final mentor I wish to mention is Dr. Robert Stein, the first Chief Medical Examiner of Cook County. In August 1984, I received a call from his secretary, asking if I could come to the medical examiner's office the next morning to assist with a case. The victim had been assaulted, raped, and strangled. As she lay on the morgue table, her shorts were pulled part way down her legs. I remember Dr. Stein's first gruff words to me, "You did not touch the body, did you?" I replied no. Later that morning, he would say to send him a bill. I said no, but he said to do so as I would be working there in the future. I would learn much from him over the years and he always treated me with respect as a peer forensic scientist.

Mentors, Levine, Snow

G19 Complex Dental Restorative Techniques: Are They Recognizable and Do They Survive Extreme Conditions?

Alistair Soon, BDS, Forensic and Scientific Services, Forensic Odontology/Pathology Unit, 39 Kessels Road, Coopers Plains, Queensland 4108, AUSTRALIA; Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214; and Peter J. Bush, BS, SUNY at Buffalo, South Campus Instrument Center, B1 Squire Hall, S Campus, Buffalo, NY 14214*

After attending this presentation, attendees will better understand how complex dental restorations withstand extreme conditions and how this knowledge may aid in routine dental identification or in Disaster Victim Identification (DVI).

This presentation will impact the forensic science community by providing the forensic odontologist with chemical and structural information of restorative materials and their interaction at high temperatures.

Recent research has shown that restorative dental materials can be recognized by microscopy and elemental analysis (Scanning Electron Microscopy/Energy Dispersive X-Ray Spectroscopy (SEM/EDS) and X-Ray Fluorescence (XRF)) and that this is possible even in extreme conditions such as cremation. These analytical methods and databases of dental materials properties have proven useful in DVI of a commercial plane crash in 2009 and in a number of other victim identification cases.

Dental materials appear on the market with ever-expanding frequency. With their advent, newer methods of restoration have been proposed and adopted in the dental office. Methods might include placing multiple layers of materials having different properties including adhesion, viscosity, working time, or curing methods. Use of different materials such as filled adhesives, flowable resins, glass ionomer cements, composite resins, liners and sealants is current.

In the normal process of forensic dental identification, restorations that exactly replicate tooth structure and color complicate the task for the forensic odontologist. With possible combinations of different materials in these restorations, the forensic odontologist is now confronted with a new difficulty: how to recognize each individual material. The question might be posed if it is even possible to perform this task.

Furthermore, an odontologist might be called upon to identify a victim under difficult circumstances, such as when presented with fragmented or incinerated remains. In these circumstances, the ability to identify specific dental materials could assist in the identification of the deceased.

Key to use of this information is whether these new materials and methods are detailed in the dental chart. Visual or radiographic inspection may not reveal the presence of a restoration, let alone the possible complex nature of that restoration.

Materials and Methods: Extracted teeth obtained from the State University of New York (SUNY) at Buffalo School of Dental Medicine were utilized in this *in vitro* study. Class II preparations in posterior teeth and Class IV preparations in anterior teeth were made. Restorations were completed using both single materials and materials in various combinations. The restorative materials used were the following: Composite resins (Grandio SO, Grandio Heavy Flow, Tetric EvoFlow, Tetric EvoCeram), glass ionomer cement (Fuji IX), and calcium hydroxide liner (Ultra Blend plus). Combinations of materials placed included Grandio Flo and Grandio SO, Fuji IX and Tetric EvoCeram, Tetric Flow and Grandio SO, and Ultrablend Plus and Tetric EvoCeram. Control samples of all dental materials were made in a ring mold. Cross-section fractured surfaces were analyzed by SEM/EDS. Elemental composition and microstructure of each material was recorded. Prepared teeth were then incinerated at 900°C for 30 minutes. As expected, these conditions caused separation of enamel from dentin and variable adhesion to, or separation of, dental materials to tooth structure. Resulting fragmented specimens were inspected by stereomicroscopy and analyzed by SEM/EDS.

Results: Post-incineration, dental restorations could be distinguished from burnt tooth structure by optical microscopy; however, it was not possible to differentiate one material from another by this means. With SEM/EDS, it was possible to differentiate the different dental materials in restorations using a combination of backscattered electron imaging and EDS analysis. Post-incineration elemental compositions matched those of pre-incinerated controls.

Odontology Section - 2015

Conclusions: Complex dental restorations can survive incineration conditions. Each material retains its individual elemental properties, and is easily distinguishable using SEM/EDS. In everyday dentistry, dental restorations are becoming more complex, especially as dentists are now utilizing different dental materials to achieve “perfect” dental restorations. This presentation is to alert forensic odontologists to these challenges and to transfer awareness to general dentists to maintain accurate dental records, as each dental material used during dental restoration could be important in the outcome of dental identification.

Forensic Odontology, Disaster Victim Identification, Dental Identification

G20 Electron Microscopy of Etched Dental Crown Surfaces and Electron Dispersive Spectroscopy (EDS) Studies Following Immersion in Hydrochloric Acid

Alexander S. Forrest, MDS, Griffith University Nathan Campus, School of Natural Sciences, Griffith Sciences, 170 Kessels Road, Nathan, Queensland 4111, AUSTRALIA; and Peter J. Hines, PhD, Queensland University of Technology, IFE Central Analytical Research Facility, Gardens Point Campus, Brisbane, Queensland 4000, AUSTRALIA*

After attending this presentation, attendees will be aware of changes in the surface appearance at the Scanning Electron Microscope (SEM) level that indicate the exposure of porcelain-fused-to-metal (PFM) dental prostheses to commercially available concentrated hydrochloric acid. This presentation documents the changes observed and this may permit other practitioners to recognize similar features should they encounter cases in which disposal of human tissues has been undertaken using similar methods.

This presentation will impact the forensic science community by providing information about the changes noted in porcelain-fused-to-metal dental prostheses when they are exposed to concentrated hydrochloric acid for a period of several days.

A number of dental PFM crowns (the original crowns) were submitted for analysis. Information was provided that it was suspected that these items had been immersed in Hydrochloric Acid (HCl) for seven days and was asked if that could be confirmed. Perusal of the literature revealed no publications that documented the changes in appearance of materials commonly used in dental crown and bridge fabrication after prolonged exposure to HCl. The outcome was therefore tested by experimentally immersing a test bridge made by the same dental laboratory using the same materials and the changes noted in the test bridge surfaces were compared with the surfaces of the original crowns.

A sample test bridge made by the same dental laboratory as the submitted (original) crowns was obtained and both the metal and porcelain parts were examined under an SEM.

The elemental composition of the metal components of both the test bridge and the original crowns was determined by Electron Dispersive Spectroscopy (EDS) which showed that the principal components in the metal structure of both prostheses were Nickel (Ni) and Chromium (Cr).

The original appearance of the metal surface of the test bridge was examined and documented as a series of images. The test bridge was then immersed in the same brand and concentration of HCl believed to have been used for the original crowns and for the same period (seven days). The same area of the test bridge was then re-examined to determine the effect of the HCl. Changes consistent with corrosion were observed in the metal. The porcelain component of the test bridge was also examined before and after immersion in the HCl and the resulting SEM scans also exhibited distinctive changes. The original crowns were then examined with the SEM. The appearance of the metal and porcelain surfaces in the original crowns were observed to show the same features as those seen in the test bridge after exposure to HCl for seven days.

The goal of this study was to determine and document the changes occurring in dental crowns, bridge metal, and ceramic materials caused by immersing them in HCl for seven days. When the resulting changes were compared with the features noted in the original crowns, they were found to be very similar, indicating the likelihood that the original crowns had also been immersed in a similar corrosive.

The identity of the specific corrosive in which the original crowns were immersed was not identified by the technique used because EDS did not identify chlorine or any other substance indicating a corrosive material as a surface component of the material being examined.

Forensic Odontology, Analytical Technique, SEM

G21 Chronological Evaluation of Bruising in Bitemarks and Blunt Trauma: Validation of the Validation of the Nuzzolese-Neri-DiVella (NNDV) Colorimetric Scale

Emilio Nuzzolese, PhD, Ambulatorio Nuzzolese, Viale JF Kennedy 77, Bari 70124, ITALY; Simonetta Lamacchia, RN, Bari, ITALY; and Giancarlo Di Vella, MD, PhD*, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will have an understanding of the standards and accuracy of a new colorimetric scale for the standardization of photographic imaging of bruises and ecchymoses.

This presentation will impact the forensic science community by presenting the results of a new and very useful tool for forensic photographic imaging and chronological assessment of bruising.

One of the more controversial aspects in the evaluation of a wound caused by trauma in a living subject is determining the time in which the trauma was inflicted; this is accomplished by evaluating its age determination according to repeatable standard procedures which are able to be measured, uninfluenced by subjectivity. Observational standardization, combined with a chromatic evaluation of the areas affected by ecchymoses, are necessary in order to obtain such a result.

The goal of this study is to verify the validity of the innovative NNDV colorimetric scale as an aid to the development of a photographic and analytic standard in the field of forensic photography, targeting chronological determination of one or more ecchymosis caused by trauma or human biting. The discriminant factor of the current technique and subjective procedure has been evaluated using the NNDV colorimetric scale, relating to the changing colors of the ecchymosis due to the passing of time by using an innovative color index. A total of 17 subjects and 22 ecchymoses were assessed and rated using this scale. Validation was performed through statistical analysis via software for the analysis of Red/Blue/Green (RBG) colors on the DigitalColor Meter. The RGB percentage value present in different areas of the ecchymosis was assessed and compared to the RGB value present on the color sections of the colorimetric scale located on the same photograph, using the same light exposure. This allowed identification of the two RGB percentage values which were most similar to each other in order to facilitate evaluation of the chromatic variants and validate the deductions obtained during the first stage of the method.

Chronological determination was accomplished by using both the subjective and objective discriminant power of each method. The power increases by combining the objective technique to the validation of the method via the use of a photo-editing software, reaching 86.36% percentage of success.

The colorimetric scale shows promise as a valuable and reliable tool for medical examiners and forensic odontologists for the assessment and standardized interpretation of bitemark and bruising age evaluation through the use of a photo-editing software.

Forensic Photography, Blunt Trauma, Bitemark

G22 Ethical Proceedings Involving Dentists in the State of Minas Gerais, Brazil

Fernanda Capurucho Horta Bouchardet, PhD, Rua Visconde Do Rio Das Velhas 60, Apto 201, Belo Horizonte, Mg 30380740, BRAZIL; Andrea Gomes Prates, DDS, Health Clinics of the Military Police, Avenida do Contorno 3300, Santa Efigênia, Belo Horizonte, BRAZIL; Mário Marques Fernandes, MSc, Ministério Público do Estado do Rio Grande do Sul, Andrade Naves, 106, 12 andar, Porto Alegre, BRAZIL; Romilda de Melo Alves Branco, DDS, Regional Council of Dentistry, Rua da Bahia 1477, Belo Horizonte, BRAZIL; and Rogério N. Oliveira, PhD, Lineu Prestes, 5081, Cidade Universitária, São Paulo 05508-000, BRAZIL*

After attending this presentation, attendees will have an overview of the annual development of ethical proceedings judged by the Regional Council of Dentistry in the state of Minas Gerais, Brazil. Specifically, the present research relates the reasons for justifying ethical proceedings and its respective sentences and penalties.

This presentation will impact the forensic science community by exposing the most common ethical violations in one of the most populous states of Brazil. The presentation specifically illustrates the relevance of properly following ethical guidelines in daily clinics in order to avoid potential ethical and legal convictions.

The Brazilian labor market annually increases with approximately 9,000 new dentists.¹ Currently, more than 250,000 dentists perform legal activities in a country with about 200 million habitants. This statistical data supports a competitive professional panorama and directly influences potential increases in the amount of daily ethical violations.^{2,3} In order to guide adequate ethical behaviors in dentistry routines, Federal and Regional Councils of Dentistry were created, including special sections for the investigation and judgment of dental ethics.⁴ Specifically, a total of 10% of the Brazilian population lives in the southern state of Minas Gerais, consequently representing a large demand for dental treatment. In this context, this study investigated the ethical proceedings prosecuted and judged at the Regional Council of Dentistry of the state of Minas Gerais, Brazil, in the period between 2005 and 2011.

A retrospective observational transversal research was designed in the database of the section of Dental Ethics at the Regional Council of Dentistry of Minas Gerais, Brazil. The sample consisted of 955 ethical proceedings detected in the period between 2005 and 2011. All data was systematically analyzed by a single observer in order to extract information concerning: the related reasons justifying ethical proceedings and the respective sentences and penalties. Descriptive statistics were performed to obtain an overview of the outcomes and an association Chi-square test was applied to assess the relationship between ethical reasons and sentences. The outcomes revealed a gradual annual increase in the amount of proceedings. Specifically, in the first year studied (2005), 49 proceedings were observed, while 249 were detected in the last year (2011). The most prevalent reasons justifying ethical suits were: (1) irregular marketing and advertising (30.4%); (2) lack of adequate technical performance (30.4%); and, (3) dental clinics not registered in their respective Regional Council (25.5%). The investigation of sentences revealed that approximately 67% of dentists were acquitted. Convicted dentists (33%) were predominantly sentenced to confidential notice (19.1%). Association tests revealed a positive relationship between reasons and sentences, indicating that proper judgments are performed once the illegal practice of dentistry, such as irregular marketing or through unregistered facilities, is highly condemned. Additionally, the conviction of inadequate technical performances highlights the need for constantly updating and improving technical knowledge.⁵

A linear growing trend of ethical proceedings was observed during the period of investigation, revealing that dental surgeons are convicted in the face of major ethical infractions. It indicates the essential role played by the section of Dental Ethics from the Regional Councils of Dentistry inspecting routine professional activities. On the other hand, surveillance is also necessary during the design of undergraduate programs in dentistry, which must contain specific education on dental ethics, dental law, and forensic odontology, properly supporting the clinical behavior of future professionals.

Odontology Section - 2015

Ethics, Dental Law, Forensic Odontology

G23 Dental Identification Using Facial Reconstruction on a Train Collision Victim's Mangled Body

Liliana Innamorato, MD, D.I.M, sezione di Medicina Legale, piazza Giulio Cesare, 11, Bari 70124, ITALY; Valeria Santoro, PhD, P.zza Giulio Cesare n.11, Bari 70124, ITALY; Alessandra Pentone, D.I.M Section of Legal Medicine, piazza Giulio cesare n.11, Bari 70124, ITALY; and Francesco Introna, MD, Dim Sezione Di Medicina Legale, P.zza Giulio Cesare 11, Bari 70124, ITALY*

The goal of this presentation is to inform attendees that the use of a positioning device can make dental identification easier, faster, and safer, as well as improving the quality of the postmortem records.

This presentation will impact the forensic science community by illustrating the advantages of dental comparison even in “extreme” cases of identification.

In Bari, southern Italy, in February of 2014, an extremely fragmented body was found scattered along the railway connecting Bari to Lecce. The body pieces were collected along 100m of train tracks in both directions, allegedly after being hit by several trains. The skull was extensively fractured with some portions of the base still present; the trunk skeleton was massively fractured, lacking its anatomical profile; and the superior and inferior limbs were reduced to several pieces. No documents or personal belongings were collected from the body; therefore, the police assumed the body was a clandestine immigrant.

The first medicolegal investigation revealed the corpse belonged to an unknown 20-to-25-year-old Caucasian man. After several days, a report was presented to the police station by people claiming a relative of theirs had disappeared several months earlier. Generic information revealed he was a 22-year-old young man affected by leukoderma, who had previously attempted suicide. The report was presented by his distant relatives with whom the man had lived several years before and with whom he was occasionally in touch.

No DNA analysis was possible for identification and no reconstruction of the soft tissue of the face or facial skull superimposition could be performed. Given that the investigator had to proceed with personal identification procedures, the police were asked to visit the relative's house and search for evidence of the victim's DNA or some of his old medical files. Luckily, a five-year-old Ortopantomography (OPT) was found; however, it was not possible to compare it with Postmortem (PM) data due to the extensiveness of the mandible and maxilla fractures. In fact, there were numerous missing structures and only a few pieces of the facial skull were still present.

It was decided that the facial skull fragments would be placed in correct anatomic position on a polystyrene head model. The model obtained was X-rayed, and the Antemortem (AM) and PM data were compared. Neither the OPT nor the X-rays showed any restored teeth. The PM radiograph of maxillary left fragment (with teeth 26-27-28) was compared to the AM panoramic X-ray. The comparison revealed a morphological compatibility between the particular radicular shape of the third molar and also of the pulpal chamber of the second molar. Moreover, there was evident compatibility of the bone profile.

In this case, it was possible to reach a positive identification through the comparison of images taken from similar angles with the positioning of the fragments on the polystyrene head model. This positioning device allowed performing a more precise morphological comparison. A better PM radiograph leads to a better AM/PM comparison.

Mangled Body, Identification, Skull Face Fragments

Odontology Section - 2015

G24 Scanning Electron Microscopy (SEM) and Energy Dispersive X-Ray Spectroscopy (EDS) of a Supposed “Gold Dental Crown”

Alistair Soon, BDS, Forensic and Scientific Services, Forensic Odontology/Pathology Unit, 39 Kessels Road, Coopers Plains, Queensland 4108, AUSTRALIA; Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214; and Peter J. Bush, BS, SUNY at Buffalo, South Campus Instrument Center, B1 Squire Hall, S Campus, Buffalo, NY 14214*

After attending this presentation, attendees will better understand the role of the SEM and EDS used in the analysis of a dental crown that was the subject of an investigation. Attendees will also learn the role of SEM/EDS in the field of forensic odontology.

This presentation will impact the forensic science community by providing an option for the analytical examination of dental materials in areas other than forensic human identification purposes. This presentation also demonstrates the application of SEM/EDS in the standard-of-care field in forensic odontology.

In today's world of global marketing, it is easy for a person to buy and sell any items overseas. It is also cheaper to have an item made overseas and subsequently imported into the country for sales; this is widely used in many industries, dentistry included.

There are several news articles about local dental laboratories outsourcing dental lab work to another country for manufacturing or of dentists sending their dental lab works overseas for fabrication of the dental work. The main reason is due to cost-cutting and is profit driven. Local dental laboratories have to comply with the rules and regulations set out by the state or country; however, overseas laboratories may not comply with any regulations at all. Dentists or the local laboratory owners will never know what the actual ingredient or actual content of the requested manufactured dental laboratory work is, until an issue is raised that requires further investigation. Is the received dental gold crown actually made of gold?

This study was consulted by a dental colleague about a full gold dental crown that discolored in less than two weeks post-cementation. The patient was unhappy and the gold dental crown was removed and refabricated. The dental colleague was told by the dental ceramist that the particular gold dental crown was made of high precious metal dental alloy (the piece of dental alloy was manufactured by a particular dental company) and was curious why the gold dental crown discolored.

SEM/EDS examination revealed that this particular “gold dental crown” was not made from high precious dental alloy and that the discoloration of the gold-colored dental crown was actually copper oxidization.

Recent research has shown that restorative dental materials can be recognized by microscopy and elemental analysis. These analytical methods of dental materials properties have proven useful in Disaster Victim Identification (DVI) and in a number of other victim identification cases. This report provides another role that SEM/EDS analysis can play in forensic odontology and dentistry in general.

This presentation highlights the importance of dental material science and scientific analysis in the field of forensic odontology.

Forensic Odontology, Dental Materials, SEM/EDS

G25 A Hot Air Balloon Crash in Wairarapa, New Zealand: A Forensic Dental Perspective

Judith A. Hinchliffe, BDS, 88 View Road, Houghton Bay, Wellington 6023, NEW ZEALAND*

After attending this presentation, attendees will understand the importance of preparation, planning, and appropriate training for Disaster Victim Identification (DVI) work. Attendees will also understand the role of the forensic odontologist in the identification of badly damaged human remains.

This presentation will impact the forensic science community by outlining the DVI response and problems associated with a hot air balloon crash in New Zealand.

On January 7, 2012, on a perfect summer day, a scenic hot air balloon trip ended in disaster when the basket collided with power lines, caught fire, and eventually crashed onto farmland near the rural town of Carterton, North Island, New Zealand. This was one of the deadliest air disasters to occur on mainland New Zealand in decades; 11 people (ten passengers and the pilot) lost their lives. Two of the passengers jumped from the balloon to their deaths; the remainder were trapped and engulfed in flames. Emergency services were at the scene very quickly and witness reports along with camera footage taken by the balloon ground crew would help to reconstruct the final moments of the flight.

This accident was managed as a DVI incident with multidisciplinary participation. One of the forensic odontologists and the regional forensic pathologist attended the scene to locate, preserve, document, and assist with the safe transportation of the remains. The badly damaged and burned bodies were taken to Wellington Regional Hospital mortuary where autopsies and identifications were undertaken. At the mortuary, forensic odontologists, fingerprint teams, and DNA teams worked alongside forensic pathologists with police and coronial support for the next week. Crash investigators, fire services, and police worked together at the scene. Surprisingly, all victims were from the region, simplifying the collection of antemortem information in readiness for comparison with the postmortem findings. Being a “closed” disaster, there was a readily available passenger list. Toxicological findings indicated the presence of tetrahydrocannabinol (a constituent of cannabis) in the body of the pilot.

Events surrounding the crash and the difficulties encountered by the DVI teams and relatives of the deceased will be outlined in this presentation. It is essential that all agencies and individuals working in this field manage the situation effectively and sensitively and learn from the process. At times of tragedy, relatives need excellent communication from those assisting to help them understand why this event claimed the lives of their loved ones. The post-incident debriefing was invaluable for improving the response for future events. An inquiry into the accident has been conducted by the Transport Accident Investigation Commission. At inquest, the families of the deceased requested that recommendations should be acted upon to prevent this type of tragedy from happening in the future. Will anything be done?

All victims were identified in the following days. After attending this presentation, attendees will understand the importance of preparation, planning, and appropriate team training for timely action when prevention fails and incidents occur. This presentation also emphasizes the role of the forensic odontologist when remains are badly damaged and commingled.

Balloon Crash, DVI, Dental

G26 Isle-Verte Disaster

*Sylvain Laforte, DMD**, Centre Dentaire Laforte, 5773 Bannantyne Street, Verdun, PQ H4H 1H2, CANADA; *Robert B.J. Dorion, DDS**, Laboratoire S.J.M.L., Edifice Wilfrid-Derome, 1701 Parthenais, 12ieme, Montreal, PQ H2K 3S7, CANADA; *Andre Ruest, DMD**, 1615 Jacques Cartier Estate, Bureau 340, Longueuil, PQ J4M 2X1, CANADA; and *Sylvain Desranleau, DMD**, Ordre des dentistes du Québec, 800 Boul René-Lévesque Ouest, Montreal, PQ H3B 1X9, CANADA

After attending this presentation, attendees will understand the importance of a well-orchestrated operations plan in order to navigate the unexpected conditions at a mass disaster site and the need for collaboration between forensic experts for a successful identification outcome.

This presentation will impact the forensic science community by helping attendees gain information on both procedural solutions to complicated climactic and site conditions in a mass disaster situation and on the lessons learned from two mass disasters occurring within months of one another, each with unique environmental issues.

The fatal fire of Résidence-du-Havre, Isle-Verte, Quebec, Canada, which occurred on January 23, 2014, struck the seniors' residence at 12:05 a.m., resulting in 32 deaths. Firefighters were called to the Résidence-du-Havre in sub-zero temperatures with a wind chill factor of -35°F which culminated in a cascading ice castle encasing the building's debris and victims alike. This presented major challenges for the recovery team.

The Isle-Verte tragedy fell on the heels of the Lac-Mégantic, Quebec, fatal train derailment in 2013, less than six month's earlier, where an unattended 72-car freight train operated by the United States-based "Montreal, Maine and Atlantic Railway" (MMA) carrying over two million United States gallons of crude oil broke away, derailed, and caught fire with multiple explosions in the center of the town resulting in 47 deaths.

The Montreal-based forensic team was cohesive and well coordinated following the Lac-Mégantic Disaster and cross-functional teams were well established to face the Isle-Verte tragedy.¹

The on-site forensic identification team included two pathologists, an experienced denar, and an anthropologist. Participants will learn the complex process of extracting cremated human remains under extreme environmental conditions. Once extracted, the human remains were bundled, packaged, numbered, and shipped to Montreal where pathologists, dentists, and DNA experts further analyzed the remains at the central forensic laboratory. The average age of the victims was 89 and most had few or no teeth. Two victims were 99 years of age. All human remains were photographed, examined, underwent fluoroscopy, and medical and dental radiography. Through the collaboration of the pathologists, odontologists, and DNA experts, 28 of the 32 victims were successfully identified. Dental identification was primarily based on trabecular bone pattern.

The Lac-Mégantic and Isle-Verte tragedies will be compared statistically and lessons learned will be shared.

Forensic Odontology, Mass Disaster Management, Positive Identification

Odontology Section - 2015

G27 Dental Identification of 530 Landslide Victims: Lessons Learned

Kyle C. Tanaka, DDS, 19320 40th Avenue, W, Ste A, Lynwood, WA 98036; Stephanie Kavanaugh, DMD*, 2731 Fairview Avenue, E, #4, Seattle, WA 98102; and Gary L. Bell, DDS, 9730 3rd Avenue, NE, Ste 204, Seattle, WA 98115*

After attending this presentation, attendees will better understand the nature of this landslide, how this type of environment impacts victim recovery and victim identification utilizing dental records. Additionally, attendees will learn how one agency utilized their local forensic odontological community to successfully identify victims.

This presentation will impact the forensic science community by further illustrating the importance of a sound working relationship between the forensic odontologist and medical examiner. Prior to the landslide on March 22, 2014, the forensic odontologists already had an established working relationship with the medical examiner's office. In addition, the local dental identification team had been trained, had experience in the medical examiner's office, and were already known to the chief medical examiner.

On Saturday, March 22, 2014, a massive landslide occurred near the small rural town of Oso, WA, obliterating a residential community along the Stillaguamish River. The mudslide also created a soft earthen dam across the river, creating a lake in the river's path upstream and a potential flooding risk downstream. Debris covered approximately one mile of State Highway 530, effectively isolating the neighboring town of Darrington. The debris field was extensive and deep: areas were covered by 10 to 60 feet of debris. The forces involved in the mudslide dismembered many victims and displaced them over an estimated one square mile. Miraculously, several people survived.

The Snohomish County Medical Examiner's Office was responsible for all victim identifications. Multiple agencies assisted in the recovery of the victims over the next several weeks. Individuals from multiple agencies also assisted directly with the medical examiner's office. During the initial days of the response, the number of missing was at times estimated to be as high 170 people. Careful follow-up of all missing person's reports (more than 500) ultimately trimmed the death toll to the more realistic 43 individuals.

Not surprisingly, the 530 Landslide was a highly publicized incident, both locally and nationally. By design and otherwise, there were many local residents volunteering onsite with recovery. Media updates of a day's events were virtually instantaneous. Appropriate scientific means of identification were viewed by some as causing unnecessary delays. In some cases, decedents had actually been recovered by local residents. At times, it was frustrating to these volunteers to accept that facial recognition alone as a means of positive identification was insufficient. The Chief Medical Examiner for Snohomish County chose to adhere to scientific methods of identification which included dental records, fingerprints, and DNA for positive identification.

While federal assets such as the **Disaster Mortuary Operational Response Team (DMORT)** would likely have been available, the Chief Medical Examiner chose to work with the forensic odontologists with whom he was already familiar and with whom their office had long-standing working relationships. Federal assets (DMORT) can be deployed rapidly; however, there would not have been the established working relationship between those forensic odontologists and the medical examiner's office. Even with a rapid DMORT deployment, that response would likely not have been as quick as what local odontologists were able to achieve. With the operating framework already in place, the medical examiner's office was able to respond to the public's need for information (i.e., identifications) promptly.

The lead forensic dental consultant for the Snohomish County Medical Examiner's Office was contacted directly by the medical examiner a few hours after the mudslide. Given the nature of the event, the Chief Medical Examiner felt that dental identification would be an important part of the victim identification process. Starting on the Monday after the mudslide, forensic dentists were at the medical examiner's office almost daily. Standard clinical dental examinations, photography, and digital dental radiography were performed on almost all of the victims. In many cases, positive identification was accomplished via dental records, providing timely information for surviving friends and family, as well as information for directing further recovery efforts.

By July 22, exactly four months after the 530 Landslide, all 43 known victims had been recovered and positively identified. Twenty-seven were identified via dental records. The remaining victims were identified by other scientific means (fingerprints, DNA, skeletal, and/or medical devices).

Dental Identification, Mass Fatality Incident, Landslide

Odontology Section - 2015

G28 Dental Identification of the 2008 Peruvian Andes Helicopter Crash Victims

Roy H. Sonkin, DDS, 45 Eagle Chase, Woodbury, NY 11797; and Richard M. Weledniger, DDS, 931 Walt Whitman Road, Melville, NY 11747-2297*

After attending this presentation, attendees will understand two of the techniques used in the identification process of a decedent.

This presentation will impact the forensic science community by demonstrating the importance of proper protocols used in the identification process to assure reliable results.

This presentation will provide an overview of the efforts made in the recovery and identification process of the victims of the 2008 *Rio Tinto Copper Mine* helicopter crash in the Peruvian Andes Mountains and will demonstrate the use of death mask reconstruction and established forensic odontologic protocols.

All too often, recovery efforts can be challenging due to environmental factors including weather, terrain, and lack of manpower. This unfortunate disaster occurred in a nearly inaccessible mountain range, in heavy weather requiring the use of specialized forces to recover remains. These factors will be discussed and the value of precise antemortem records and their interpretation will be presented. Additionally, this presentation will discuss the difficulty encountered when instrumentation and technology are limited.

The discussion will stress the importance of understanding other cultures and their impact on the identification process. This presentation will also demonstrate the need for those of lesser forensic experience to be given the guidance and knowledge necessary to perform a proper forensic dental identification — this includes understanding the value of separating and labeling personal effects to minimize commingling and, in so doing, potentially facilitate the identification process. Emphasis will be placed on the necessity of “guest” odontologists to conform to the protocols of the “host” while gently introducing techniques that as yet may be unfamiliar and, by doing so, advancing the level of knowledge and ability of all, in an effort to reach positive outcomes.

The interaction between forensic professionals and the importance of mutual respect will be discussed as it applies to sharing of ideas and techniques that may be foreign to non-dental investigators. Additionally, attendees will come to understand the necessity for modifying protocols and demonstrating flexibility when called upon to act as a forensic odontologist rendering proper identifications in a difficult environment.

Forensic Odontology, Unidentified Persons, Helicopter Crash

Odontology Section - 2015

G29 The Reno, Nevada Air Race Accident

Donna J. Hellwinkel, DDS, 4555 Saddlehorn Drive, Reno, NV 89511; Ellen G.I. Clark, MD, Washoe County ME/Coroner, 10 Kirman Avenue, Reno, NV 89502; and Rudolph Bein, BA, Washoe County MEO, 10 Kirman Avenue, PO Box 11130, Reno, NV 89520*

After attending this presentation, attendees will be acquainted with information regarding the Reno, NV, Air Race accident which occurred at 4:25 p.m. on September 16, 2011, and resulted in 11 fatalities and approximately 60 injuries.

This presentation will impact the forensic science community by providing an understanding of the vital role the dental team plays in the management of the identification of the victims of a Multiple Fatality Incident (MFI).

On the afternoon of September 16, 2011, at a popular annual air show in Reno, NV, located in Washoe County, a modified World War II-era fighter plane crashed into the edge of the VIP grandstands. Eleven people, including the pilot, were killed and approximately 60 spectators were injured, many suffering amputations.

This incident occurred within the jurisdiction of the Washoe County Medical Examiner's Office (WCMEO). The WCMEO, located in Reno, NV, is responsible for forensic death examinations for all of the State of Nevada (with the exception of Las Vegas and several southern Nevada counties) as well as a few northern California counties. The office covers an area of approximately 100,000 square miles and a population of 800,000.

The WCMEO was notified and responded to the former Stead Air Force base, approximately 12 miles from the morgue. An initial site assessment was completed, and recovery, antemortem data collection, and postmortem data collection teams were activated. This scene assessment led to the discovery of many fragmentary remains and an indeterminate number of deceased victims. Survivor and decedent dismemberments were commingled with the crash site debris.

This presentation will illustrate how the WCMEO recovered and made scientific identifications of these remains. Specifically, it will demonstrate how the dental team, composed of one forensic odontologist and one WCMEO death investigator, positively identified victims using traditional methods of comparison of antemortem and postmortem dental records and dental radiographs. One intact body from the scene as well as 16 individual dental fragmentary remains, which included teeth, were identified. All positive dental identifications were completed by September 21, 2011. Subsequent DNA sequencing, one to two days later, confirmed the dental identifications.

Information will also be provided on how other postmortem modes of scientific identification (fingerprints, radiology, and DNA) were used to identify and to re-associate remains. All remains were able to be released within one week of the incident. This rapid release highlights the teamwork required of law enforcement, first responders, medical examiner office personnel, and members of the health care community when dealing with the aftermath of an MFI. It also clearly demonstrates the respect the forensic science community has for victims and families during a very stressful and emotional time.

Forensic Science, Forensic Odontology, Multiple Fatality Incident

Odontology Section - 2015

G30 Identification of an Unknown Sailor From the December 7, 1941, Attack on Pearl Harbor

John A. Lewis, Jr., DDS, 407 Heritage Place, Flowood, MS 39232*

After attending this presentation, attendees will have gained an understanding of the forensic identification procedures used to identify the skeletal remains of a previously unidentified American sailor who was killed during the December 7, 1941, attack on Pearl Harbor. Attendees will also learn of efforts made to identify other previously unidentified victims of the Pearl Harbor attack.

This presentation will impact the forensic science community by describing the forensic identification procedures used to identify Americans lost during past conflicts.

On Sunday, December 7, 1941, the tranquility of the island of Oahu, HI, was shattered by the Japanese attack on the American Pacific Fleet anchored at Pearl Harbor. By the end of the day, close to 2,400 military and civilian personnel were dead, killed in the attack which launched the United States into World War II.¹

One of the 162 ships and vessels within Pearl Harbor proper on that day was the U.S.S. *Curtiss* (AV-4), a seaplane tender. During the attack, the *Curtiss* was hit twice by Japanese aircraft.¹ The second contact resulted in the deaths of 21 sailors from the *Curtiss*. Two of the *Curtiss*' crew members were unaccounted for. One body was unidentifiable at the time and was ultimately buried as an unknown at the National Memorial Cemetery of the Pacific, also known as Punchbowl.

Pearl Harbor survivor Ray Emory was a young Seaman 1st Class stationed aboard the U.S.S. *Honolulu* which was in port at Pearl Harbor on December 7, 1941. In recent years, Emory began researching the unknown victims of the attack on Pearl Harbor who were buried at Punchbowl. Through the efforts of Mr. Emory, the unknown remains of a sailor was disinterred and positively identified using forensic odontology, forensic anthropology, and mitochondrial DNA testing.

The American military has a solemn pledge to never leave one of its own on the battlefield. This includes using every available tool to identify its unknown war dead from past wars. Even though the attack on Pearl Harbor occurred almost three-quarters of a century ago, forensic science was used to identify an unknown American killed in the attack which launched the United States into World War II.

Odontology Section - 2015

G31 Forensic Dental Examination of Disinterred 19th-Century Archaeological Remains

Thomas J. David, DDS, 1000 Johnson Ferry Road, Bldg H, Marietta, GA 30068; and Adam J. Freeman, DDS, 22 Imperial Avenue, Westport, CT 06880*

The goals of this presentation are to distinguish between archaeological remains and more recent burials and to compare and to contrast dental restorative treatment from the 19th, 20th, and 21st centuries.

This presentation will impact the forensic science community by discussing the historical significance of forensic dental information from 19th-century dental remains.

The discovery of gold along Whitewood Creek in the fall of 1875 led to the settlement of Deadwood, SD. Deadwood's first cemetery was established out of necessity for the proper disposal of human remains. This cemetery was originally located about one-quarter mile from Deadwood's central business district. It is unknown who established the cemetery or when the first burial occurred, since newspapers in the town were not established until June of 1876. Nevertheless, many of the town's newspapers provided news articles and obituaries about individuals buried in the original cemetery. The first cemetery did not have a formal name and was referred to by many names, including "the Deadwood Cemetery," "cemetery on the hill," "City Cemetery," and "old graveyard in South Deadwood." As a matter of fact, a newspaper article once referred to the cemetery by two different names on the same day. The creation of Mt. Moriah Cemetery in 1878 led to the downfall of Deadwood's first cemetery; however, after the establishment of Mt. Moriah Cemetery, Deadwood's first cemetery would be called "Old Deadwood Cemetery."

Approximately 122 individuals were buried in Deadwood's first cemetery from 1875 to 1878. In June of 1877, one newspaper reported there were 80 burials in the cemetery. Two noteworthy individuals buried in the first cemetery included James Butler "Wild Bill" Hickok and Methodist minister Henry Weston Smith. Both of these individuals were later exhumed and reburied in Mt. Moriah Cemetery in 1879 and 1883, respectively.

In the spring of 2006, construction workers discovered human remains while in the process of replacing a retaining wall and the unearthed remains were sent to Minnesota for forensic analysis. It was determined that the individual was an adult male who was approximately 25-34 years of age and stood 5'4"-5'8" in height. The ethnic origin was determined to be Asian, Mongoloid, or Native American. This individual was reinterred in the Mt. Moriah Cemetery on July 28, 2010. A monument was placed on the grave that acknowledged the possible Native American and Chinese heritage of this individual.

In March of 2012, construction workers unearthed a fully articulated coffin burial while replacing a retaining wall at 66 Taylor Avenue in Deadwood. At that time, both Deadwood Historic Preservation officials and South Dakota State Archivists were on hand to exhume the burial. They found approximately 99% of the skeleton, with the exception of one tooth and a few finger and toes. The remains were subsequently transported to a forensic anthropologist for analysis. It was determined that this individual was a white male of 18-24 years of age and was 5'4"-5'8" in height.

After a forensic anthropologic analysis, the remains were transported to Marietta, GA, for a forensic dental analysis. This analysis was conducted on March 1, 2014, and the results will be discussed in detail. Despite multiple forensic analyses, no cause of death has been determined.

G32 Adam Mayes: America's Most Wanted — A Lack of Wisdom?

Edgar W. Turner, DDS*, 410 Farino Way, Somerville, TN 38068

After attending this presentation, attendees will understand the problems that may be encountered in a dental identification involving the presence, or lack thereof, of third molars in various stages of development. This case will demonstrate cross-arch variations that may occur in the development of third molars within the same individual.

This presentation will impact the forensic science community by explaining the premise that if a tooth is missing in antemortem dental records but is present in the postmortem dental records, this generally constitutes an exclusion in terms of dental identification.

In April 2012, Jo Ann Bain and her three daughters were reported missing from the rural town of Whiteville, TN. Although they were scheduled to move out of state the next day, an investigation by law enforcement officials led to the conclusion that the family may have been kidnapped by a family acquaintance, Adam Mayes. An Amber Alert was issued for the missing children. The nature of the case resulted in local, state, and federal authorities becoming involved. As the investigation continued, Mayes was placed on America's Ten Most Wanted Criminals list by the Federal Bureau of Investigation. Adam Mayes became the Most Wanted Man in America after the bodies of Jo Ann Bain and one of her daughters were found buried in a shallow grave in Mississippi, while the remaining two children continued to go missing.

The partially decomposed remains of the mother and one daughter were transported to the West Tennessee Regional Forensic Center in Memphis, TN, for a complete autopsy and identification. While the dental identification of the mother was straightforward, identification of the daughter became problematic when three of the decedent's third molars were found to be present in the antemortem panoramic radiograph; however, postmortem radiographs revealed that all four third molars were present. The absence of a tooth in antemortem radiographs, which is subsequently found in postmortem records, is generally recognized as an unresolved discrepancy and routinely results in an exclusion in terms of a dental identification. In this particular case, two forensic odontologists independently reviewed the case and concluded that a positive identification could be made in spite of the discrepancy with the third molars. This presentation will discuss the problems associated with the identification as well as developmental discrepancies in third molars.

Mayes was eventually located in Mississippi by state authorities along with the two missing children. The case was adjudicated in 2013. As part of this presentation, the final resolution of this case will be provided, including the status of Adam Mayes, the missing children, and the accomplices involved in this case.

Identification, Odontology, Exclusion

Odontology Section - 2015

G33 Two Teens, Midnight, and a Porsche® Carrera® — What Could Go Wrong?

John P. Kenney, DDS, MS, 101 S Washington Street, Park Ridge, IL 60068-4290*

The goal of this presentation is to discuss the importance of complete dental records being submitted for an identification.

This presentation will impact the forensic science community by educating both the odontology community as well as fellow forensic scientists as to why complete antemortem records are requested before beginning an identification.

In the summer of 2010, two 17-year-old males were returning to their home in the suburbs of Chicago around 11:30 p.m. in a Porsche® Carrera® titled in the driver's name. They were traveling at a high rate of speed (estimated at 100+mph) and sideswiped a Dodge® minivan along Interstate 88 near Winfield, IL. Fortunately for the van's passengers, the van driver was experienced and able to maintain control of his vehicle. Unfortunately, the young driver was not able to do so; his vehicle spun out of control on the toll road, ran up a concrete embankment supporting an overpass, and flipped several times before stopping and bursting into flames.

Illinois State Police and Fire Rescue from Winfield, IL, responded, but all they could do was extinguish the fire and recover two young male bodies. The body of the owner was rapidly identified via excellent dental records from the young man's orthodontist. Intraoral photos, a cephalogram, and panoramic X-ray all compared favorably with the postmortem dental examination; however, identification of the second victim was problematic. There were a number of discrepancies between the written records, the antemortem X-rays, and the postmortem findings. It was clear to the investigator that while human error in charting was a possibility, the more likely answer was overbilling of procedures to the young man's parent. Fortunately, it was possible to make a positive identification based on the objective dental X-ray evidence. Had no antemortem X-rays been available, the identification would have had to wait for fingerprint or DNA comparison. In this situation, a delay or exclusion based on the written dental record alone would have had serious ramifications because the young friends' faith stipulates burial within 24 hours. The investigator contacted the treating dentist in the process of the investigation and suggested that perhaps better record keeping was in order.

Radiographs, Odontogram, Dental Treatment Narrative

G34 The Case of the Missing Mandible

Roger D. Metcalf, DDS, JD, Tarrant County Medical Examiner's District, 200 Feliks Gwozdz Place, Fort Worth, TX 76104; and Janice W. Klim-Lemann, DDS*, 1802 Canyon Road, Redlands, CA 92373*

After attending this presentation, attendees will be aware of how a missing mandible contributed to the resolution of three separate cases.

This presentation will impact the forensic science community by highlighting the importance of retaining records for as long as possible.

In 1986, a farmer in rural Dallas County, TX, was ploughing his field and came upon a decomposing human body. The farmer contacted the Dallas County Sheriff's Office to report the death and the Dallas County Medical Examiner's Office (MEO) was duly notified in turn. The medical examiner's investigators recovered the remains, but the decedent's mandible was not found. The decedent was examined at the morgue and the cause and manner of death were determined. The decedent was identified by comparison of antemortem and postmortem dental radiographs as Mr. A. The treating dentist was from Ohio and was subpoenaed to appear at the perpetrator's trial in Dallas County in order to "prove up" the dental records of the decedent. The perpetrator was tried and convicted. The treating dentist believes the original dental radiographs were retained by the MEO; however, the MEO states the radiographs were returned.

In 2010, in neighboring Denton County, TX, a death was reported to the Tarrant County Medical Examiner's District (the jurisdiction of the Tarrant County office also includes Denton, Parker, and Johnson Counties). The deceased was found seated on a farm combine in a remote area of his farm with an apparent self-inflicted gunshot wound to the head. The decedent was identified at the scene as Mr. B. by his ex-wife and also by his brother. The deceased had been despondent over the break-up of his family and financial woes as well. He was examined at the Tarrant County morgue and the cause and manner of his death were determined.

In 2011, the Tarrant County Medical Examiner's District was notified of a body found in a partially burned house in rural unincorporated Tarrant County. Upon investigation, the "body" was determined to be incomplete. In fact, the unidentified remains consisted of only a single human mandible found sitting incongruously in plain view on a kitchen counter. It was learned the house had belonged to Mr. B.; Tarrant County medical examiner's investigators found the cause of the fire had been ruled as arson — later investigation revealed Mr. B. had apparently set fire to his home in Tarrant County, then traveled to his farm in Denton County, where he committed suicide. The charred house was being cleaned and the fire damage was being repaired by the bank that had taken possession of the house prior to putting the house up for sale. The house had sat empty and unattended for approximately a year after the fire.

Attendees of this presentation will learn how these cases were intertwined and their eventual resolution. The case report underscores the utility of practitioners retaining dental records for as long as possible and raises the issue that, although the Identification (ID) was eventually made by DNA comparison, were the available dental records sufficient to have made an ID?

Dental ID, Odontology, Mandible

G35 Single Tooth Dental Identification Assisted by Digital Superimposition

*Amber D. Riley, MS**, 9855 Erma Road, #103, San Diego, CA 92131; *Anthony R. Cardoza, DDS*, 9530 Cuyamaca Street, #101, Santee, CA 92071; and *Raymond Johansen, DMD*, 601 E Arrellaga Street, Ste 202, Santa Barbara, CA 93103

After attending this presentation, attendees will better understand how specific utilization of Adobe® Photoshop® features may assist their ability to examine dental evidence forensically.

This presentation will impact the forensic science community by informing attendees that forensic dental comparison is an ideal instrument in death investigation because of the longevity and durability of the dental anatomy, even in scenarios of extreme heat, trauma, and decomposition.

In this case, there were numerous obstacles to performing a traditional, straightforward dental identification, not the least of which were the age of the antemortem dental records furnished for comparison, but even more significant to the investigation was the scarce amount of postmortem dental evidence that was provided by investigators for analysis, which consisted of only one tooth.

In November 2012, family members of a man reported missing found and turned in a single tooth from a site where previously skeletonized human remains and personal effects had been recovered in Imperial County, CA. Forensic dental consultants examined the tooth to determine: (1) if it was indeed a human tooth; and, (2) if it would be significantly unique for an expert opinion to identify or exclude the missing person.

There was discussion of using the tooth in an attempt to recover DNA from the pulp tissue for comparison with known family sources; however, any collection procedures would destroy the tooth for further odontological evaluation and it was uncertain that useable tissue for DNA analysis could even be collected from the tooth. Therefore, it was agreed that the risk of destroying the very limited evidence was too high and a dental comparison was the first and best option to investigate identity.

A full series of dental radiographs dated August 5, 1996, were collected from the missing person's dentist and multiple radiographic and photographic images were taken of the single tooth at the Office of the Medical Examiner in San Diego, CA. It was determined that the tooth was a virgin, permanent lower right molar. Based on the size, anatomy, distal curvature, and lack of space between the roots, it was agreed that the tooth was most likely a third molar, tooth #32 in the Universal Numbering System, or tooth 48 in the **Fédération Dentaire Internationale** (FDI) World Dental Federation notation.

Both the antemortem and postmortem radiographs were digitized and uploaded into Adobe® Photoshop® to allow a digital superimposition of the radiographs at varying opacities from 10% to 100%. The software also allowed the tooth images to be realigned on a consistent, measured, and reproducible gradient as well as their size enlarged to examine and measure minute and intricate anatomical details from both antemortem and postmortem images, without distortion and with a reproducible history of any manipulations made to the original image.

The chief forensic dental consultant using digital superimposition, digital enhancement of anatomical landmarks, and the measuring tools available in Photoshop® determined that the postmortem single tooth evidence and the antemortem dental records of the missing person were consistent to the level of probable (more likely than not). The Chief Medical Examiner signed the case out as positive identification based on the supporting quantitative data provided in the consultant's report detailing the process used and the images and data upon which his opinion was based.

Digital, Dental, Identification

G36 Identification by Photograph: A Case Presentation

Barbara L. Needell, DMD, 5280 N University Drive, Lauderhill, FL 33351*

After attending this presentation, attendees will understand how to overlay and compare antemortem and postmortem photographs to make a positive dental identification.

This presentation will impact the forensic science community by demonstrating a method of dental identification when dental radiographs are not available or are insufficient.

Dental identifications are usually accomplished by comparing antemortem and postmortem radiographs. In the absence of this information, other methods of identification must be found: (1) non-dental, such as DNA or fingerprints; or, (2) other dental, such as written records or photographs. When making an identification by photograph, how to use the tools (e.g., Photoshop®) to make an accurate comparison must be understood.

In 1981, a young woman, Tina, went missing in south Florida. She had recently moved from Ft. Meyers, FL, to live with a man who promised her a modeling career. When her parents discovered this, they went to Hollywood and met with the man. With their approval, Tina remained with this man who was a photographer. One week later, Tina's sister notified Pembroke Pines police that Tina was missing and they had lost contact. In 1982, a skeleton was found in West Palm Beach, FL, the county just north of Broward County where Hollywood/Pembroke Pines is located. The skeleton was cataloged and, for 31 years, stored as unknown remains.

In April 2013, the missing person's case was reopened due to an inquiry by the victim's sister. Her son had alerted her that there were unknown remains in West Palm Beach which reminded him of his aunt's case. Tina's sister was able to provide several photographs showing dentition. Photographs of the skeleton were taken in similar positions to the antemortem pictures. Using Photoshop®, the pictures were adjusted to the size of the skeletal teeth. This was accomplished by using several points on the teeth and measuring the distances between them. The overlays were created using two techniques of the Photoshop® program. One used the opacity slide function; the other used the pencil drawing function to outline the teeth. Both were successful and the skeleton was positively identified as Tina.

This presentation will demonstrate methods used to overlay antemortem and postmortem photographs. This technique aids in dental identification in the absence or insufficiency of antemortem radiographs.

Dental, Photograph, Identification

G37 A Case for the Records — The Importance of Antemortem Records in Making a Positive Dental Identification

Randolph L. Mitchell, DMD, 47 William Street, Lyons, NY 14489*

After attending this presentation, attendees will better understand the need for patience as antemortem records come into the medical examiner's office. Attendees will be able to sort out what information is key to the identification and what information helps to support the identification, while not actually being exemplars.

This presentation will impact the forensic science community by providing attendees with an appreciation of the need for complete antemortem records in a dental identification. Attendees will also appreciate the need for good documentation of treatments performed on patients and the role these documents play in dental identification.

This presentation will use a case study to demonstrate how important each piece of information that is provided to the medical examiner is in clarifying what appeared to be a major inconsistency between the decedent's antemortem and postmortem records. The net result is that it is the combination of all of the antemortem records provided, though they came from different sources and at different times in the investigation, that helped to explain the inconsistency between the postmortem dental and radiographic examinations completed at the Medical Examiner's Office (MEO) and the digitally transmitted antemortem radiographs initially provided by the decedent's dentist, which helped to make a positive dental identification possible in this case.

An interesting part of both the antemortem and postmortem records in this case was a personal effect found with the remains that was very tempting to use as a part of the evidence in the identification. Despite the temptation to use this personal effect in the identification, the personal effect was an object, not unique to the decedent, nor an actual part of the remains. Therefore, the personal effect should not be used as an exemplar in the scientific identification process, but may possibly play a supporting role of adding consistency with the antemortem and postmortem records, although on its own it adds nothing to the actual identification.

This case verifies that antemortem information drives dental identification. Recordkeeping, whether written or radiographic, from the decedent's primary caregiver or from a one-time treatment by a specialist, is extremely important in helping to make a positive dental identification. All records should be conveyed to the MEO when the primary caregiver is presented with a subpoena *duces tecum* by the MEO.

Identification, Records, Concurrence

G38 Fire, Fraud, and Forensics: A Complex Case Study in Dental Identification

Jacqueline S. Reid, DDS, 390 Main Street, Chatham, NJ 07928; Diane Karluk, MD, Middlesex County MEO, 1490 Livingston Avenue, North Brunswick, NJ 08902; and Andrew L. Falzon, MD, Mater Dei Hospital, Dept of Pathology, Msida MSD 2090, MALTA*

The goals of this presentation are to create a better understanding of the importance of dental records in a multi-victim fatality event involving children and to explain the necessity for open, professional communication between the treating dentist and the forensic dentist for an expedient result to the identification process.

This presentation will impact the forensic science community by illustrating the need for effective communication and cooperation between professionals involved in forensic cases and by exposing some of the ethical challenges faced during attempts to definitively identify victims in high-profile, tragic events.

On February 23, 2012, a tragic house fire claimed the lives of five victims, four of which were children. Multiple techniques were required to identify the victims due to an absence of antemortem dental films for two of the children and the adult, and fraudulent dental treatment notes for three of the four children. The techniques included: (1) age estimation to differentiate two of the children who were under the age of five years; (2) the use of distinctive dental characteristics, antemortem photography, and exclusion criteria to identify the adult; and, (3) the use of a law enforcement agency to definitively identify that three of the children's antemortem dental treatment notes were fraudulent.

The case discussion includes: (1) antemortem records review; (2) identification of the child victim; (3) age estimation techniques/procedures; (4) communication between the treating dentist and the forensic dentist; (5) deciphering fraud in the dental record; (6) ethical considerations for reporting fraudulent dental/medical records; (7) working under close media scrutiny; and, (8) lessons for community out-reach and education.

The sequence of events unfolded as follows. Initially, the Middlesex County Medical Examiner's Office obtained incomplete dental records for three of the children, all of whom were treated by the same dentist. The incomplete records contained panoramic dental radiographs of two of the children taken 11 months prior to the fire. A second request for the complete antemortem dental records was then made. The dental autopsies were begun using the incomplete records. After reviewing the antemortem radiographs, two of the victims were positively identified; however, when the additional dental records were received prior to the completion of the postmortem examinations, discrepancies existed between the dental treatment notes and the postmortem findings. The dental treatment notes indicated that multiple restorations were placed on all of the patients under the dentist's care after the date(s) of the antemortem X-rays. In fact, the restorations were not present in the postmortem examinations of any of the victims.

Upon completing the postmortem examinations, attempts to contact the treating dentist via telephone were made. The sole purpose of directly contacting the dentist was to rectify the discrepancies between the dental treatment notes and postmortem examinations so that accurate identification of the victims could be made. The dentist did not answer any questions that were asked during the phone conversation that would clarify the antemortem records, nor did he return any additional phone calls made at the behest of the medical examiner. Due to the absence of a response from the dentist, the assistance of the Middlesex County Prosecutor's Office was requested. The investigation that was subsequently launched led to the arrest of the dentist. The delay in identification of the victims caused by the discrepancies between the dental records and the postmortem examinations led to a media storm.

Ultimately, the two older children were positively identified by X-ray comparison, the two younger children were differentiated via age estimation, and the adult victim was identified by exclusion criteria and known individualizing characteristics captured in antemortem photographs. The dentist pled guilty to three counts of fraud and one count of obstruction. He was convicted, sentenced to two years of probation, and levied fines. The dentist is currently being investigated by the New Jersey State Board and the Attorney General's Office for Medicaid fraud.

Dental Identification, Fraud, Forensics

G39 Recovery and Processing of Multiple Partial and Total Cranial Fresh Cadaver Heads Purportedly for Surgical Teaching

Taylor L. Gardner, BfSc, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Yolanda Nerkowski, BA*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Robert E. Wood, DDS, PhD*, Princess Margaret Hospital, 610 University Avenue, Toronto, ON M5G 2M9, CANADA*

The goals of this presentation are to: (1) make attendees aware of the presence in the community of fresh, non-embalmed human surgical specimens available on the private market; and, (2) detail an occurrence where 15 whole or partial human heads were turned into a coroner's service for disposal and how they were evaluated and documented prior to their disposal.

This presentation will impact the forensic science community by assisting attendees to: (1) recognize the importance of having a mass fatality plan in place with an emphasis on dental identification; (2) have an awareness of the procurement, selection, and suitability of human specimens used for teaching purposes; and, (3) be cognizant of unethical practices related to full-body donation, including informed consent and precious metal "harvesting."

Medicine and science benefit from the use of human specimens for teaching and research, from educating medical students to taphonomy lab studies. This presentation will impact the forensic science community by making members mindful of how procurement occurs, why specimens must be suitable for their intended use, and selective disclosure of information regarding the fate of a body when consent is given. An increased awareness and ability to recognize disrespectful practices will contribute to the reporting of, and investigation into, unsavory and perhaps unlawful interference involving human specimens, and guide its regulation and oversight.

The Office of the Chief Coroner (OCC) was asked for cremation certificates for 15 human heads. These were procured for a dental implant surgery course. Information was obtained that the supplier — from outside of Canada — may have been under investigation unrelated to these specimens. Therefore, the OCC decided to review and confirm specimen identity.

This situation was treated like a "miniature, controlled, multiple-fatality incident," providing organized specimen analysis and as a training exercise for morgue staff in multiple-fatality protocols. Through joint efforts of specialists including a forensic anthropologist, advanced practice pathology assistants, a forensic pathologist, and an odontologist, the specimens were photographed, examined, and documented including: CT scanning, dental radiography, and DNA sampling. A summary examination and report on all specimens were completed.

After the exercise, it was discovered that this raised more questions than answers. The majority of specimens were clearly not suitable for implant training, having one or more of the following problems: (1) being completely dentate with few sites for implantation; (2) advanced sinus pneumatization; (3) inadequate alveolar bone; and, (4) presence of grossly carious roots. This made these "wasted" specimens. Furthermore, there was little uniformity in sectioning and disarticulation of specimens. Subjects were received as either partial, half, or full-head specimens. The variety of dissections observed begs the question of whether those providing their consent for body donation were informed of the extent to which their body would be "altered" or whether their body would be exported. It was also observed that more than a third of the specimens exhibited some loss of coronal structure and cast restorations, as evidenced by residual crown-cementation material and in the absence of any trauma/caries.

Additionally, teeth with non-precious materials in these same specimens were present and unaltered. The removal of these restorations, presumably posthumously, may have been deliberate and it is possible that these restorations contained precious metals that could be sold profitably for scrap.

Positive identification was achieved for all specimens. The early years of acquiring human cadavers for medical education purposes is tarnished. As far back as the late 1700s in North America, medical schools required specimens. Laws permitted the use of a deceased individual for this purpose if they were a criminal, the body was unclaimed, or the individual had given prior consent — which was rare. This lack of supply generated a market for human cadavers and "resurrectionists" would retrieve the recently buried for profit. This unlawful practice continued for years. In Ontario currently, bequeathals of a body for education and research is regulated by the Trillium Gift of Life Network Act (2002) and the Human Tissue Donation Act. Provided that there is no objection by next-of-kin, an individual can give consent prior to their passing or next-of-kin have authority to consent. The act states that the "use of the body or

Odontology Section - 2015

for the removal and use of the specified part or parts” may be used for therapeutics, medical education, or scientific research. Although there is no age restriction, suitability is based on cause of death, illnesses, recent surgical procedures, and weight. Legally, the anatomy inspector must have documented the name, sex, age, birthplace, and last place of residence, as well as the name of the school and date where the body was delivered.

Anatomical Teaching Specimens, Dental Identification, Postmortem Interference

G40 Identifying the Edentulous

Corinne D'Anjou, DMD*, 222 rue l'Espérance, St-Lambert, PQ J4P1Y2, CANADA; Robert B.J. Dorion, DDS*, Laboratoire S.J.M.L., Edifice Wilfrid-Derome, 1701 Parthenais, 12ième, Montreal, PQ H2K 3S7, CANADA; and Alistair Soon, BDS, Forensic and Scientific Services, Forensic Odontology/Pathology Unit, 39 Kessels Road, Coopers Plains, Queensland 4108, AUSTRALIA

After attending this presentation, attendees will learn information regarding a new method of identifying the edentulous which may assist in victim identification.

This presentation will impact the forensic science community by introducing a new method of identification based upon the maxillary sinus configuration/morphology assessed from panoramic radiographs.

Identifying the edentulous is challenging in many respects. In part, the absence of teeth critically diminishes the use of thousands of dental reference points used in standard dental identification. The trabecular patterns in the edentulous may also be too few or unique to be used in the identification process.^{1,2}

Results of a previous study suggest that radiographic identification of the edentulous has a high error rate and should be dual reported.³ Forensic practitioners are well aware that dental prostheses should be labeled but, practically speaking, this recommendation is not generally accepted by the dental profession nor is it practiced. Moreover, many edentulous either do not have prostheses, do not wear them, or remove them at night. The present study seeks to produce a reliable source of reference for comparing Antemortem (AM) to Postmortem (PM) panoramic radiographs of the maxillary sinuses.

The technique provides a mathematical assessment for comparing the curves on the maxillary sinus floor and walls of an AM panoramic radiograph to a PM panoramic radiograph. The mathematical formula that will represent the sinus configuration will use strategic points on the sinus. Even the relatively amorphous sinus can be represented by a group of functions that define the different curves of the sinuses. Once the mathematical functions of both AM and PM curves are known using the method presented, and comparing the percentage of similarity of curves and concordant points on both curves, an identification can be established or refuted.

To test the present hypothesis, 50 pairs of panoramic dental radiographs (Orthopantomogram (OPG)) were collected. Each pair were taken at least five years apart using the same panoramic device. The initial OPG dental radiograph was assigned as the AM dental radiograph, and the other OPG dental radiograph taken at least five years later was assigned as the PM dental radiograph. The set of OPG dental radiographs of each patient was calculated and compared using the method presented that evaluates the correlation between AM and PM sinus formulas.

Forensic Odontology, Edentulous, Maxillary Sinuses

G41 Cougar Attack Fatality

Peter W. Loomis, DDS, 700 Ranchitos Road, NW, Los Ranchos, NM 87114*

After attending this presentation, attendees will understand how a cougar attacks, injuries caused by such an attack, a comparison of the dentitions of two different-sized cougars to the patterned injuries on the victim, and dental and oral anatomical comparative anatomy of humans and cougars.

This presentation will impact the forensic science community by providing information on how a cougar attacks, the bitemark-patterned injuries made by cougar teeth, the dental anatomy of cougar teeth, and the postmortem anthropophagy patterns on the victim. A discussion will be included on the failure to initially capture the cougar, causing community concern that a killer cougar was on the loose, which resulted in the killing of additional wildlife, including a second cougar, a bear, and a javelina, as well as causing injury to a horse and its rider.

A cougar attacked and killed a man in a semi-rural area of southwest New Mexico in June 2008. An attempt to kill the cougar that was feeding on the remains failed and the cougar escaped until it was ensnared one week later and dispatched with a bullet. Necropsy was performed on the animal and a comparison of its dentition to the bite injuries was made along with that of a second cougar that was captured and killed. The multiple-patterned injuries to the head and neck and subsequent postmortem anthropophagy feeding patterns were examined and compared to the teeth of a large adult male and a smaller adult female cougar.

Cougars typically attack prey from the rear by surprise, leaping on the back of the prey, clamping down on the back of the neck with its cuspid teeth, and clutching around the animal's rib cage with its massive forepaws, sinking the claws into flesh to ensure there is no escape. This is when the prey falls and the cougar places its focus on the lateral and anterior aspect of the neck, suffocating the prey by crushing the trachea and/or transecting major neck vessels with its powerful bite. A cougar can also break the neck of its prey when it is on the animal's back by forcing the head back with its forepaws while continuing to clamp down on the back of the neck. As in this case, a cougar often carries or drags its kill to a secluded area to feed on the viscera, neck, shoulders or hindquarters, frequently leaving drag marks at kill sites. They frequently try to cover their kills with soil, vegetation, or snow. The viscera may be covered separately and "scrapes" or "scratches" composed of mounds of soil, grass, or leaves are often found around carcasses and trails.

Noteworthy intra-oral trauma and tooth discoloration to both cougars was evident from their ensnarement and struggle to self-extricate from the snares. The excised tongue of the cougar, including its long, keratinized filiform papillae, the deeply furrowed palatal rugae, and the teeth class characteristics will be visually compared to the human mouth and dentition.

Cougar, Attack, Animal Bite

G42 Estimating the Incidence of Dog Bite-Related Injuries in Australia From 1999 to 2012

Mithun Rajshekar, MFSc, 2/67 Olinda Grove, Mt Nelson, Hobart, Tasmania 7007, AUSTRALIA; Leigh Blizzard, PhD, Menzies Research Institute Tasmania, 17 Liverpool Street, Hobart 7000, AUSTRALIA; Roberta Julian, PhD, Tasmanian Institute of Law Enforcement Studies, University of Tasmania, Sandy Bay, Hobart 7007, AUSTRALIA; Marc Tennant, PhD, Centre for Rural and Remote Oral Health, University of Western Australia, Perth 6009, AUSTRALIA; Anne-Marie Williams, PhD, School of Medicine, University of Tasmania, Hobart 7000, AUSTRALIA; Laurence Walsh, PhD, University of Queensland, St Lucia, Brisbane, AUSTRALIA; Alexander S. Forrest, MDS, Griffith University Nathan Campus, School of Natural Sciences, Griffith Sciences, 170 Kessels Road, Nathan, Queensland 4111, AUSTRALIA; and Gary Wilson, MS, Advanced Animal Dentistry, Wellington Point, Queensland 4160, AUSTRALIA*

After attending this presentation, attendees will understand the extent to which dog bites are a public health and forensic problem in Australia.

This presentation will impact the forensic science community by explaining how injuries due to dog bites are a largely unrecognized and preventable public health problem in countries with a high level of dog ownership. Reviewing the incidence of dog bite-related injuries will provide evidence for the development of improved public policy and prompt further research in forensic analysis of bitemarks.

Background: Previous estimates for Australia, made for the period 2001 to 2003, indicate that 1,800-1,900 persons require hospital treatment each year for bites from dogs and, on average, one or two of them will die from their injuries. The most common victims of dog bites are children between the ages of zero and nine years. Recent data are lacking because no studies have been conducted since to estimate the annual incidence of hospitalization due to dog bites in Australia.

Goal: To estimate the incidence of dog bite-related injuries in Australia from 2003 to 2011.

Methodology: Summary data on hospitalizations due to dog bite-related injuries with a World Health Organization International Statistical Classification of Diseases and Related Health Problems, Tenth Revision, Australian Modification code w54.0 (external cause of injury code) in each state or territory of Australia during the 2003-2011 study period were collated. The data were sourced from the injury surveillance units or health department registry of each state and territory in Australia. Annual and age-specific incidence density were calculated using mid-year population estimates (Australian Bureau of Statistics), trends in annual rates were estimated using Poisson regression, and sampling variation (super populations approach) has been summarized using 95% confidence intervals.

Results: In Australia during the period 2003-2011, there were 21,905 dog bites recorded as having required hospital treatment. They occurred at an annual rate of 11.6 (95% CI 11.5, 11.9) per 100,000. Age-specific rates were 28.6 (95% CI 27.7, 29.6) per 100,000 among ages 0-4 years, 20.6 (95% CI 19.8, 21.4) per 100,000 among ages 5-9 years, 11.6 (95% CI 11.0, 12.2) per 100,000 among ages 10-14 years, and 9.5 (95% CI 9.4, 9.7) per 100,000 among those 15 years of age or older. Overall, the annual rates increased from 10.1 (95% CI 9.8, 10.4) per 100,000 at the start of the period (average 2003-2004) to 14.1 (95% CI 13.8, 14.5) per 100,000 at the end of the period (average 2010-2011 when 6,264 bites occurred). The increase in rates was statistically significant ($p < 0.001$) and occurred at an increasing rate ($p < 0.001$).

Conclusion: A significant increase in hospitalization rates resulting from dog bites occurred during 2003-2011. These more recent estimates indicate that hospital-treated dog bites are now occurring at the rate of 3,132 bites per year. This study establishes the extent of dog bites as a public health and a forensic problem, thereby instigating a thought process to develop advanced forensic techniques to identify unknown perpetrating dogs involved in dog bites.

Dog Bites, Bitemark Analysis, Incidence Rates

G43 Visualization of Histological and Physiological Criteria Used in Dental Methods of Age Assessment

*Aime Conigliaro, MA**, Fort de Rosny, 1 boulevard Théophile Sueur, Rosny sous-bois 93110, FRANCE; and *Charles E. Georget, PhD*, 5 Rue Voltaire, Amboise 37400, FRANCE

After attending this presentation, attendees will understand the interest in using, as rationally as possible, the criteria included in these age-assessment methods, especially as each image of comparison can more accurately target the score for each criterion.

This presentation will impact the forensic science community by demonstrating through clinical cases that the estimated age of a victim can vary by a few years depending on the benchmark used to evaluate the criteria. The pictorial catalog of comparison was developed with the contribution of optical microscopy and will make experts aware that it is easier and more accurate to compare a picture with other pictures than a picture with drawings or descriptive texts.

The goal of this work is to develop easier and more efficient applications to estimate the age of an adult victim at the time of death. The study mainly includes the improvement of the interpretation of histological and physiological criteria used in the age assessment methods currently existing. Of concern are six factors: (1) abrasion; (2) periodontal disease; (3) root transparency; (4) secondary dentine; (5) cementum apposition; and, (6) root resorption.

All criteria were studied using the same protocol. The height of periodontitis raises no problem of interpretation because it only depends on a measure of the whole tooth in its socket before extraction, if possible. On the contrary, after extraction and fine cutting of the tooth on its main axis in buccolingual on the mesial and distal sides, the other five criteria are the subject of observations. These latter lead to the choice of a representative image of a score.

Generally, the interpretation advocated by this study of the age assessment methods is based on a macroscopic observation. This study is original as it uses a microscope connected by a Universal Serial Bus (USB) connection to the computer; the display of the image is observed on a screen before its capture. These enlarged views allow easier and more reliable reading of the factors studied. This is especially the case for secondary dentin apposition, cementum apposition, and root resorption where the macroscopic interpretation is often difficult as it is not totally visible.

After having established the picture catalog of comparison of all the factors, the latter is tested by means of teeth extracted from patients of a known age. The evaluation of the imaging is made by calculating the age for the methods of estimation using some or all of the histological and physiological criteria.

Conclusion: To conclude this work, the procedure is applied to an assessment of the age of a real victim. The use of the picture catalog of comparison allows easier and more reliable reading of the factors studied, specifically the cementum apposition and root resorption; however, age assessment is more efficient.

Age Assessment, Optical Microscopy, Postmortem

G44 The London Atlas — A New Method for Dental Age Estimation

Sakher J. AlQahtani, PhD*, King Saud University, College of Dentistry, Riyadh 11451, SAUDI ARABIA; Mark Hector, PhD, Administration Office, Dental School, Park Place, Dundee DD1 4HR, UNITED KINGDOM; and Helen M. Liversidge, PhD, Queen Mary University of London, School of Dentistry, New Road, London E1 2AT, UNITED KINGDOM

The goal of this presentation is to present a new method of dental age estimation and evaluate how it performs in comparison to other methods.

This presentation will impact the forensic science community by presenting a new method which has an electronic version that will revolutionize dental age estimation.

The purpose of this research was to develop a comprehensive, validated, evidence-based, practical, user-friendly atlas of dental age estimation and compare its performance with two widely used atlases.

Diagrams representing ages from 28 weeks *in utero* to 23 years were developed in The London Atlas based on the radiographic appearance of tooth development in 528 individuals aged 2-23 years and 176 neonates using the median stage of tooth development for each tooth in each age category/chronological year.¹

Accuracy was determined by ageing skeletal remains/radiographs of 1,514 individuals (aged 32 weeks *in utero* to 23 years) using The London Atlas (LA), the Schour and Massler (SM) atlas, and the Ubelaker (Ub) atlas.¹⁻³ Estimated age was compared to real age. Bias, absolute mean difference, and proportion of individuals correctly assigned by age were calculated. Intra-observer variation (Kappa) was measured by re-assessment of 130 radiographs.

To test the application of The London Atlas, a questionnaire was used to validate its use. Ninety third-year dental students were divided randomly into three subgroups; the researcher's identity was unknown to the students. Each group used one of the three atlases to estimate the radiographic age of six individuals and complete the questionnaire.

Excellent reproducibility was observed for all three atlases (Kappa: LA 0.879; SM 0.838; and, Ub 0.857). LA showed no bias ($P=0.720$) and correctly estimated 53% of the cases. SM and Ub showed significant bias by consistently underestimating age ($P=0.026$ and $P=0.002$, respectively) with 35% and 36% correctly estimated for SM and Ub, respectively. The mean absolute difference for LA (0.72 years) was smaller than SM (1.15 years) and Ub (1.17 years).⁴ LA was preferred over the other two atlases in all quality measures tested (clarity, design, simplicity, and self-explanation)

In conclusion, The London Atlas represents a substantial improvement over existing atlases facilitating accurate age estimation from developing teeth. Development of interactive online and mobile app versions is complete.

Age, Estimation, Dental

G45 Dental Age Estimation: The 18-Year Threshold — A Source of Error Explored

*Victoria Sorrell Lucas, PhD**, King's College London Dental Institute, Dept Orthodontics, Fl 25, Guy's Tower Wing, Great Maze Pond, London SE1 9RT, UNITED KINGDOM; *Fraser McDonald, PhD*, King's College London, Fl 25, Guy's Tower Wing, Great Maze Pond, London SE1 9RT, UNITED KINGDOM; and *Graham J. Roberts, MDS*, King's College London, Dept Orthodontics, Fl 25, Guy's Tower Wing, London Bridge, London SE1 9RT, UNITED KINGDOM

The goal of this presentation is to demonstrate how the use of simple probability without age stratification can lead to errors in age assignment at the 18-year threshold. Attendees will learn that a subject in the 17.00 to 18.99 age bracket will as likely be assigned an age *under 18* as to be assigned an age *over 18*. A method for overcoming this difficulty will be explored.

This presentation will impact the forensic science community by explaining the rationale for this cause for concern and, with audience participation, by exploring a way of overcoming this rationale.

Introduction: Since the publication of the probability thresholds in the study of third molar development the process of age assessment for emerging adults has been greatly simplified.¹ This seminal paper did not fully take into account the phenomenon of “censoring” the Age at Attainment (AaA) of Stage H.² This has resulted in datasets for Stage H being top heavy. The consequence is that the mean AaA is erroneously elevated. This results in age assignments that are too harsh on subjects in the 17.500 to 18.499 age range. Hence children are unfairly assigned adult status.

Materials and Methods: The DARLInG data base comprising 2,986 UK Caucasian cases was used as the Reference Data Set. The validation set for this study comprised a balanced sample of Dental Panoramic Tomographs (DPTs) of 1,000 females and 1,000 males in the 16.00 to 25.99 age range. For each six month age span a convenience sample of 50 females and 50 males at each six month age interval were examined. These were derived from the radiographic archives of Guy's and St Thomas' National Health Service Trust. Only Dental Panoramic Tomographs with at least one third molar were used.

The stage of development is defined using the anatomical descriptions from 1973.³

The estimated age was compared to the chronological age and the accuracy of the age assignment designated as correct or incorrect to give simple counts. These simple counts were then used to calculate the probability of a subject of unknown age being correctly assigned to childhood or adulthood.

Results:

Age Band	<18 Correct		<18 Incorrect		>18 Correct		>18 Incorrect	
	n	%age	N	%age	n	%age	N	%age
17.5 to 17.99 f	35	70%	15	30%				
17.5 to 17.99 m	41	82%	9	18%				
18.00 to 18.499 f					24	48%	26	52%
18.00 to 18.499 m					25	50%	25	50%

Conclusion: There is a 50% risk (0.5 probability) that a child will be assigned adult status. This, ethically is unacceptable.

Stage H Errors, Age at Attainment (AaA), Probability Values at 18

Odontology Section - 2015

G46 Immigration-Related, Dental Age-Estimation Cases for the Del Rio and Laredo Sectors of the United States-Mexico Border in Texas

David R. Senn, DDS, University of Texas HSC San Antonio, 7703 Floyd Curl Drive, Mail Code 7919, San Antonio, TX 78229-3900*

After attending this presentation, attendees will have a better understanding of the complexity of the illegal immigration problem as well as the nature and scope of immigration-related, dental age-estimation procedures performed by a forensic odontologist for a portion of the United States-Mexico border in Texas.

This presentation will impact the forensic science community by raising awareness of one aspect of the complex and continuing problems confronted by multiple entities including, but not limited to, immigration and law enforcement personnel as they attempt to manage various problems associated with illegal border crossings.

Persons who are apprehended by federal, state, or local agencies following illegal border crossings constitute a serious problem. This problem has existed for many years but has changed in recent history because of (or despite) increased efforts by federal and state governments. The United States government has dedicated vast resources into increasing border security over the past decades including adding more than 650 miles of border fences and adding 21,000+ border patrol personnel according to one study. That same study reports that more than \$18 billion was spent on border enforcement in 2012.

A report from the Council of Foreign Relations includes information indicating that the best outside estimate is that the United States government's apprehension rate has increased in recent years because of increased border security. Others report that the problems with the United States economy have more to do with the decrease in illegal border crossings. Most studies estimate that the government now intercedes in about half of all illegal border crossings from Mexico. Most also agree that the incentive for illegal immigration is not going to disappear in the foreseeable future.

The Border Security, Economic Opportunity, and Immigration Modernization Act (S.744), if signed into law, will establish a 90% "effectiveness rate" as a goal for each of nine separate sectors of the southern United States border.

The effectiveness rate is the percentage calculated by dividing the number of apprehensions and "turn backs" in a given sector during a fiscal year by the total number of illegal entries in that sector. The nine sectors from west to east are San Diego, El Centro, Yuma, Tucson, El Paso, Big Bend, Del Rio, Laredo, and Rio Grande Valley. This presentation includes discussion of dental age estimation cases for the Del Rio and Laredo Sectors only.

The management of illegal immigrants in all sectors includes the necessity of discriminating between adult and juvenile detainees. Juveniles and adults are detained separately and the juvenile facilities are perceived to be preferable to the adult. Consequently, detainees of all ages often claim to be "under 18." Eighteen is the current age of majority in all four states bordering Mexico. Absent definitive proof of actual chronological age, immigration agencies sometimes request age estimation services from forensic odontologists to help them differentiate likely adults from likely juveniles. The recent increase in illegal immigration levels of younger juveniles both accompanied and unaccompanied has generated some activity in the dental estimation of age for younger juveniles.

This presentation will describe the history, nature, and scope of the immigration-related age estimation activities of one forensic odontologist from 1998 through 2014 for two sectors of the United States-Mexico border in Texas.

Age Estimation, Odontology, Immigration

G47 Dental Age Estimation: Appropriate Censoring of Stage H

Graham J. Roberts, MDS*, King's College London, Dept Orthodontics, Fl 25, Guy's Tower Wing, London Bridge, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, Fl 25, Guy's Tower Wing, Great Maze Pond, London SE1 9RT, UNITED KINGDOM; and Victoria Sorrell Lucas, PhD, King's College London Dental Institute, Dept Orthodontics, Fl 25, Guy's Tower Wing, Great Maze Pond, London SE1 9RT, UNITED KINGDOM

The goal of this presentation is to draw attention to a widespread error in the process of age estimation at the 18-year threshold.

This presentation will impact the forensic science community by showing attendees how to appropriately censor Stage H.

Attendees will learn how to censor Stage H of 3rd molars and will become aware of the errors resulting from no-censoring of Stage H of third molars. Attendees will also learn that failure to censor stage H leads to unrealistic overestimates of the mean Age at Attainment (AaA) for Stage H of 3rd Molars.

Introduction: Since the publication of the probability thresholds in the American Board of Forensic Odontology study of third molar development, the process of age assessment for emerging adults has been simplified.¹ This seminal paper did not take account of “censoring” the AaA of Stage H.² This has resulted in datasets for Stage H being top-heavy. The consequence of this is that the mean AaA is erroneously elevated.

Materials and Methods: A review of the literature revealed 14 studies that used the eight Tooth Development Stages described in 1973.² The mean AaA designated as x-tds and the Standard Deviation designated as sd-tds for stage H were extracted from the data.

Uncensored and Censored* Data for Stage H — males						
Year	Ethnicity	x-tds (years)	sd — tds (years)	Minus 3 sd (years)	Plus 3 sd (years)	Range (years)
2003	Spanish	19.45	1.15	16.00	22.90	6.90
2005	Spanish	19.74	1.09	16.47	23.01	6.54
2014	United Kingdom Caucasian	19.98	2.09	13.71	26.25	12.54
2008	Italy Caucasian	20.02	1.46	15.64	24.40	8.76
2002	Hispanics United States	20.10	2.60	12.30	27.90	15.60
2007	Turkish	20.10	1.80	14.70	25.50	10.80
2009	Korean	21.10	1.20	17.50	24.70	7.20
2004	Spanish	21.86	2.47	14.45	29.27	14.82
2012	Northeast Malaysian	22.37	1.98	16.43	28.31	11.88
2004	German Caucasian	22.50	1.70	17.40	27.60	10.20
2004	Japanese	22.50	1.80	17.10	27.90	10.80
2004	South African	22.60	1.90	16.19	28.30	12.11
2010	South China (Han)	22.72	2.27	15.91	29.53	13.62
2010	First Nations (Canada)	23.20	2.80	14.80	31.60	16.80

The Table is ordered by the AaA (x-tds), smallest to largest. It is clear that some of the AaA values are far too high. The assessment is that this cut-off starts at 21 years — the Korean data.

Odontology Section - 2015

From this AaA value, there are increasing AaA which reaches 23.20 years for the First Nations of Canada. The consequences of these elevated AaA values for the First Nations study can be seen in the Minus 3sd and Plus 3sd columns where, for example, the lowest value is 14.80 years and the highest value is 31.60 years. This is clearly not tenable. This problem can be overcome by censoring the data.³ There are three possible methods for this: (1) sort the ages for TDSs with the accompanying TDS so when stage G no longer appears, the censor point can be identified; (2) create a small graph with the Cumulative Probability — this enables identification of the censor point; and, (3) create a data set censored at the upper stage by the largest value of Stage G — beyond that point all the ages are for Stage H only. The data is delimited to +/- 3sd. This is achieved by using a simple calculation within a worksheet and then to extract only the data that lies between these lower and upper values with a spreadsheet with calculated values, viz.: =IF(AND(A5>=D\$5,A5<=D\$6),A5,""). This will limit the data set to +/- 3 sd values. This incorporates 99.7% of the population data and censors the data appropriately. This results in realistic values for the AaA of Stage H.

Age Estimation, Censoring Stage H, Age at Attainment (AaA)

G48 Unique Dental Morphology With Concurrent Dental Developmental Anomalies: A Case Study Demonstrating the Utility of a Multidisciplinary Approach

Judy Y. Marshall, DMD, Marshall Family Dentistry, 3443 Tamiami, Ste F, Port Charlotte, FL 33952; Jan Westberry, DMD, 2234 State Road 44, New Smyrna Beach, FL 32168; and Michael W. Warren, PhD, C.A. Pound Human ID Laboratory, Cancer & Genetics Research Complex, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610*

After attending this presentation, attendees will understand how the medical examiner, the forensic odontologist, and the forensic anthropologist collaborate to analyze a case involving a human calvarium.

This presentation will impact the forensic science community by presenting a case with unique dental morphology and by demonstrating the utility of dental radiography beyond antemortem/postmortem comparisons.

A human skull was discovered when a man was clearing some brush behind trash bins in southwest Florida. The medical examiner assumed jurisdiction of the skull and requested that the forensic odontologist conduct a postmortem dental examination in the absence of antemortem records. The medical examiner also requested that a forensic anthropologist perform an osteological examination to establish a biological profile and record individualizing characteristics that might be useful for personal identification.

Following guidelines and standards established by the American Board of Forensic Odontology, the initial dental examination included dental charting, digital photographs, radiographs, impressions, and a written report.¹ Oral examination revealed significant occlusal wear and the external morphology of the maxillary incisors exhibited shoveling, double shoveling, and lingual pits. Radiographs demonstrated that the maxillary right third molar had closed apices and multiple teeth exhibited developmental anomalies.

The anthropological examination performed at the C.A. Pound Human Identification Laboratory included both non-metric and FORDISC® metric analysis.² The remains were classified as an adult, Native American male. This finding and the taphonomic appearance of the remains suggested that the calvarium was that of a prehistoric Native American and, thus, of no medicolegal significance.

Teeth are useful in anthropologic research because of their preservability, observability, variability, and heritability.³ These traits are also the reasons why teeth are valuable in forensic dental cases; however, anthropologists and odontologists tend to view teeth from different perspectives. Anthropologists focus intently on the surface details of teeth while odontologists look inside the teeth with radiographs. The presence of shoveling, double shoveling, and interruption grooves in the incisors are morphologic patterns present in this case which have been documented by anthropologists to occur at higher frequencies among those of Native American ancestry. Dental radiographs documented that the maxillary right third molar was a taurodont and the maxillary incisors exhibited dens invaginitis with distinctly bifurcated anterior pulp chambers. The use of cone beam computed tomography enabled 3D visualization of the teeth. To determine whether the dental morphology and anomalies in this case represent rare incidental findings or whether there is a correlation between the observed dental morphology and anomalies will require additional scientific research.

This case demonstrates how, under the jurisdiction of the medical examiner, the forensic odontologist and the forensic anthropologist are able to contribute to the disposition of a forensic case. Additionally, this case presentation demonstrates how forensic odontologists use dental radiography beyond forensic identification.

G49 A New 12-Month, University-Based United States Fellowship Program in Forensic Odontology

Richard A. Weems, DMD, MS, 592 Oakline Drive, Birmingham, AL 35226; Lee Wilson, DMD, UT Med Center Knoxville, Dept of General Dentistry, Medical Bldg A, Ste 340, 1930 Alcoa Highway, Knoxville, TN 37920; Michael P. Tabor, DDS, 310 23rd Avenue, N, Nashville, TN 37203; William M. Bass III, PhD, University of Tennessee, Dept of Anthropology, Knoxville, TN 37996; Darinka Mileusnic-Polchan, MD, PhD, UTMCK, Dept of Pathology, 1924 Alcoa Highway, Knoxville, TN 37920; and Murray K. Marks, PhD, University of Tennessee, Dept of Pathology, 1924 Alcoa Highway, Box 108, Knoxville, TN 37920*

After attending this presentation, attendees will better understand traditional forensic odontological education in the United States and how a new full-time odontology fellowship will offer a different model of training as related to curriculum design, student assessment techniques, and alignment/collaborations with other forensic-related institutions and agencies.

This presentation will impact the forensic science community by enhancing attendees' abilities to critique and develop unique and evolving educational programs in forensic odontology.

Currently, obtaining training and required qualifications in forensic odontology in the United States is gained through a relatively few program opportunities, none of which are full-time/continual in nature. During the 1970s, acquiring odontology skill sets was basically limited to two options: (1) identifying an experienced, credentialed, and willing forensic odontologist to serve as a mentor; or, (2) participation in the week-long forensic odontology course sponsored by the Armed Forces Institute of Pathology (AFIP).

The mentorship model was often hit or miss in that locating such a willing *and* experienced individual was often difficult. Also, most forensic organizations now require that applicants for full membership and/or credentialing submit a more formal and organized curriculum conducted by a recognized and credentialed faculty. The weight or validity of the training course is also increased based on the topics and the amount of hands-on experiences conducted by the faculty.

Unfortunately, the AFIP course is currently unavailable due to governmental budget restraints and has an uncertain future. The loss of this traditional opportunity has created concern among many regarding the long-term need to create a cadre of highly-trained and competent forensic odontologists for the future.

Recently, there has been modest growth in training opportunities through the development of other excellent forensic odontology courses, though many are held biennially. These are typically affiliated with a medical examiner's office or university-sponsored programs which confer credibility. These programs range from three to six continual days to a robust "fellowship" program consisting of eight to nine onsite sessions lasting three to four days over a 22-month period. These programs are continuously evaluated by the Odontology Section of the American Academy of Forensic Sciences to judge each course's value in achieving "full membership" status in the Academy.

Recently, an advisory committee was formed in the Department of General Dentistry at the University of Tennessee Medical Center to explore the possibility of creating a new forensic odontology training program and graduate curricula. The committee included the Chair of the Department of General Dentistry, two board-certified forensic odontologists, two board-certified forensic anthropologists, the Dean of the University of Tennessee Medical Center's Graduate School of Medicine, and the Chief Medical Examiner of the Knox County Regional Forensic Center.

Consequently, a new program in forensic odontology has been developed and includes all of the forensic scientists mentioned above as faculty. It is based within the newly created Division of Forensic Odontology/Human Identification in the Department of General Dentistry at the University of Tennessee Medical Center's Graduate School of Medicine. The program duration is 9 to 12 months of continual graduate training involving case-based didactic lectures, demonstrations and hands-on exercises in the areas of dental identification, disaster victim identification protocol, bitemark analysis, human age/sex/ancestry estimation, and jurisprudence. A significant amount of the practical component of the residents' experience involves real-time casework through a collaborative effort with the aforementioned Forensic Center which serves approximately 20 counties in East Tennessee. A cooperative research alliance has also been created with the University of Tennessee's National Forensic Academy's Outdoor Research Facility in Oak Ridge, TN.

The Fellows' foundational knowledge and specific skillsets will be continually assessed through literature review presentations, specific procedural competencies, high stakes hands-on examinations, and a continuing portfolio of the residents' actual forensic casework. A project of original odontological research with national forensic meeting presentation and eventual publication will complete the training.

G50 A Forensic Odontology Aspect of Disaster Victim Identification Across Members of the International Organization for Forensic Odonto-Stomatology

Shirley Miranda, MScD*, 3302 Gaston Avenue, #711, Public Health Sciences, Dallas, TX 75246

The goal of this presentation is to present protocols from members of the International Organization of Forensic Odonto-Stomatology (IOFOS) that will aid in the sharing and decipherment of new technologies, management of unique cases, improving methodologies, and assisting fellow nations in disaster management.

This presentation will impact the forensic science community by promoting efficient and reliable guidelines in the identification of human remains in order to achieve concise and effective results.

Discussion: When it comes to the forensic odontology aspect of Disaster Victim Identification (DVI), each country operates differently as per the political climate or individual background/organization. It is a well-established fact that the Interpol Standing Committee on DVI includes forensic odontology as part of their guidelines. Forensic odontologists play a key role in DVI. Interpol provides designated forms and protocols to aid odontologists as part of their DVI manual.¹ This results in quality assurance as recommended by the IOFOS.

Besides evidence collection, examination and recording, interpretation, reporting, and presentation, protocols are one of the key tasks of forensic odontologists involved during a DVI when tsunamis, plane crashes, terrorist attacks, etc. occur.²

A study of protocols from members of the IOFOS will aid in the sharing and decipherment of new technologies, management of unique cases, improved and revised methodologies, and assisting each other in disaster management. The advantage of sharing protocols would be to promote efficient and reliable guides in identifications of human remains. When a standardized operation procedure has been utilized and maintained, a more concise and effective result can be obtained.

Goal: The goal of this study is to research and evaluate policies, protocols, programs, and an associated documented system of the forensic odontology aspect of DVI from countries who are current members of the IOFOS.

Methods: Currently, the IOFOS consists of 31 member nations. All participating members were emailed with a brief description of the study and a request to share the odontology aspect of the DVI protocol that was currently being used.

Results: The forensic odontology protocols of all the members who willingly shared this information were evaluated for efficiencies and deficiencies that included similarities, differences, and technology among others.

Conclusion: Improving guidelines based on research and recommendations will enable a nation to be self-sufficient as well as help in the aid of other nations during their time of need with the utilization of shared manpower and technology.

G51 Current Trends in Forensic Odontology Research Nearly 30 Years Later

Shirley Miranda, MScD*, 3302 Gaston Avenue, #711, Public Health Sciences, Dallas, TX 75246; and Jeffrey W. Shirah, DMD, 5000 Saddle Drive, Austin, TX 78727

The goal of this presentation is to augment previous forensic research and indicate areas of limitations as well as aid in the development and improvisation of research and training facilities, including those in dental and dental hygiene schools.

This presentation will impact the forensic science community by promoting discussion concerning areas of deficiency in various fields of forensic odontology which may expose the need for more in-depth and advanced research in order for this field to continue to be a respectable, justifiable, and reliable scientific process in the medicolegal system.

Forensic odontology involves a science that is interwoven with the medicolegal system. The American Board of Forensic Odontology (ABFO) by itself conducts annual workshops in dental identification, civil litigation, age estimation, and bitemark analysis.

Deoxyribonucleic Acid (DNA) analysis methods, which are basically DNA profile tests in forensic dentistry that offer a new perspective in human identification, are a current research trend that is gaining widespread recognition. These tests are known to be highly reliable and are well documented as acceptable legal proofs in the judicial system. Bitemark analysis is still a highly controversial topic but newer trends in research could indicate a favorable use of this analysis as a scientific and reliable method.

This research study is based on a similar study done by Katz and Cottone in 1988 where current trends in forensic odontology were researched over a seven-year period (1980-1987).¹

Objective: The goal of this study is to review research presented in forensic odontology from the annual meeting of the American Academy of Forensic Sciences (AAFS) in the past ten years. An update on how forensic odontology research has evolved, including the introduction and efficiency of DNA analysis in the last decade, will be identified and discussed. A study in these areas will augment previous research and indicate areas of limitation as well as aid in the development and improvisation of research and training facilities, including those in dental and dental hygiene schools.

Method: Abstracts from 2004-2014 presented during the annual meetings of the Odontology Section of the AAFS were reviewed to determine the direction of forensic odontology research. The categories were based on the type of presentation which included literature reviews, case reports, newer techniques, research, and education. The topics of the presentation will include mass disaster, bitemarks, human identification, child abuse, legal issues, photography, and other miscellaneous areas.

Conclusion: The premise of this study will be to ensure that areas of deficiency in various fields of forensic odontology may expose the need for more in-depth and advanced research in order for this field to continue to be a respectable, justifiable, and reliable scientific process in the medicolegal system. The information obtained in this study would benefit a range of professionals from forensic odontologists, medical examiners, detectives, profilers, emergency room personnel, and coroners to law enforcement officials and social services.

G52 Forensic Odontology Science: Applications in the Family of Forensics

Peter J. Bush, BS, SUNY at Buffalo, South Campus Instrument Center, B1 Squire Hall, S Campus, Buffalo, NY 14214; and Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214*

The goal of this presentation is to provide examples describing how the application of forensic dental science can prove useful in a variety of contexts.

This presentation will impact the forensic science community by illustrating that knowledge gained in forensic dental research can reach across disciplines and circumstances.

This presentation consists of a description of a dental standard-of-care case, a sting operation conducted by a private detective, an industrial product investigation, and technique development for a crime lab.

“The Paperclip Dentist”: The State University of New York (SUNY) Laboratory for Forensic Odontology Research (LFOR) was contacted by the Massachusetts District Attorney to assist in a standard-of-care case. Among other questionable practices, a dentist was suspected of placing posts made from paper clips as definitive restorations. The insurance company was billed for final post and core placement. The material used in this tooth was examined. Analysis of the materials recovered with Scanning Electron Microscopy and Energy Dispersive X-Ray Spectroscopy (SEM/EDS) revealed zinc-coated iron and not stainless steel. The analysis aided in arraignment and subsequent conviction of the dentist.

Pet Crematoria Sting Operation: A private detective made an inquiry about how the SUNY laboratory could assist in analysis of material from a sting operation he had conducted. He was investigating the practices of individual cremation of pets and had heard that the SUNY laboratory had performed research on cremated remains.

In order to conduct his investigation, the detective had prepared a number of specimens and submitted them to pet crematoriums. The specimens consisted of mechanical toy cats. All the mechanical parts were removed and the empty cavity stuffed with five pounds of hamburger meat. Thus, all that was given to the crematoria was cloth/artificial fur and hamburger. Several of the crematoriums returned tins containing ashes with material that appeared to be calcined bone. Of course, this would not be possible given the nature of the specimens. Laboratory analysis confirmed the nature of the returned ashes as calcined bone, which brought into question the practice and expense of pet cremation. Some months later, a surprise visit was made to the SUNY laboratory by a New York State licensing investigator to verify the analysis that had been performed. New York state law requires crematoria to be licensed.

Foreign Object in Foodstuff: A sample from a candy-making company was sent to the SUNY laboratory for analysis. The company had received a customer complaint regarding a foreign object in a caramel nut chew. Having constructed a database of physical and chemical properties of dental materials, which has proven useful in resolution of victim identification in a plane crash and other national and international cases, it was no surprise that the database came to the laboratory’s aid in this circumstance. SEM/EDS identified the material as tooth structure with an adhering restoration. The restoration was a composite resin filling that was able to be identified by brand. The foreign material came from the customer who was eating the candy, not from the manufacturer. The analysis and resulting reward will be illustrated.

Retrieval of Hidden Pistol Serial Numbers: Hi-Point polymer pistols are popular street guns; however, the manufacturer of the polymer pistol has acted responsibly in providing hidden serial numbers inside the polymer housing. This was done so that serial numbers could not be readily removed by filing; however, retrieval of the serial numbers poses the problem of destruction of evidence. The question was raised by the Erie County crime laboratory as to whether dental/medical X-ray imaging could resolve the serial numbers non-destructively. A portable dental X-ray generator and digital sensor, together with subsequent image processing, was used to successfully reveal the hidden numbers.

Beyond the usual practice of victim identification by dental methods, whether it is a criminal case, forensic technique development, civil practices, or quality assurance for a business, forensic dental science has provided a basis for resolution of a number of issues and continues to be vital in the family of forensic sciences.

Odontology, SEM/EDS, X-Ray

Odontology Section - 2015

G53 Application of Digital Laboratory and Clinical Dental Evidence

Raymond G. Miller, DDS, 122 Covington Road, Buffalo, NY 14216; and Mary A. Bush, DDS, SUNY at Buffalo, B1 Squire Hall, 3435 Main Street, Buffalo, NY 14214*

After attending this presentation, attendees will be informed about a new and increasing source of dental evidence to assist in casework.

This presentation will impact the forensic science community by increasing awareness of antemortem digital data sources as well as by opening discourse on the associated concerns and potential issues.

Advances in technology have rapidly changed the way the dental profession diagnose and treat their patient population. Initially, advances in computer technology were directed toward practice management. In more recent times, these advances have been directed in the diagnostic and restorative disciplines of dental practice. Computer matching software as well as digital radiography have played a significant role in mass disasters and most medical examiners' offices. Now digital restorative dentistry, besides modifying how patients are treated and methods of practice, provides a new and unique application and valuable source of antemortem information.

In situations such as a mass disaster or the discovery of unknown remains, the location of quality antemortem dental records is a critical step in the identification process. Through the years, forensic dentists have been very innovative in their methods of locating useful dental records. When reaching roadblocks through the normal pathway of collecting evidence from dental care providers, other avenues have been followed. These have included non-traditional methods such as medical radiographs of the skull, photographs, insurance company data, and military records. Requirements or mandates for dentists to maintain records vary from state to state. In the United States, the time frame can range from no mandate to ten years. There are regions of Canada that mandate up to 30 years of retention. During the search for records, there are times that dead ends are met and records have been purged with no recovery possible. History has also shown that the disaster itself can destroy the antemortem evidence. This was true in the crash of Arrow Flight 1285 in Gander, Newfoundland, and during hurricane Katrina.

The advances in digital dentistry have added a whole new dimension and data source in antemortem record acquisition. Digital scans of the dentition for prosthetic fabrication, orthodontics, protective mouth guards, and other oral appliances have become commonplace in dental practices and will only increase in time. Digital scans have been used for study models, single crowns, bridges, complete full dentures, implant design and fabrication, and orthodontic applications. This digital data may be stored in the office of the provider or in the dental laboratory's database. Being able to follow leads to connect the dots and locate the data may be frustrating, but in the end may be very rewarding.

These records will provide restorative information along with anatomical variances. Through these records, dentist can acquire 3D dental casts or models as well as high-definition digital photos. 3D printers can fabricate dental casts from the stored data. These records can be useful to compare restorative patterns, tooth position shape and size, and other possible identifiers such as rugae patterns. Besides the anticipated problems associated with locating these records, concerns associated with data storage need to be considered. The potential for data to be purged based on limits of storage capacity is a real issue. These issues will need to be addressed and possibly require legislative action and mandates. Custodial issues as well as ability to access, manage, and utilize the data are other concerns.

Digital Dental Evidence, Technology, Antemortem Records

G54 Failure to Diagnose Oral Cancer Is Not Always Malpractice

Yolanda Nerkowski, BA, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Taylor L. Gardner, BFSc, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Robert E. Wood, DDS, PhD, Princess Margaret Hospital, 610 University Avenue, Toronto, ON M5G 2M9, CANADA*

The goals of this presentation are to: (1) provide the attendee with information as to the reasons and length of delay in oral cancer diagnosis in a major tertiary cancer center, from the standpoint of both the patient and the practitioner; and, (2) relate, by way of a case report, what can go wrong when a cancer is missed at the very earliest stages and how this can lead to erroneous legal conclusions.

This presentation will impact the forensic science community by informing attendees that the incidence of oral cancer is increasing and the general principles of cancer treatment, across all disease sites, is that early diagnosis improves survival rates; however, in order for an oral cancer to be diagnosed, it must “declare itself” by being detectable. Additionally, both the patient and practitioner have responsibilities in the diagnostic process. Practitioners and experts should be aware of reasons for not detecting oral cancers and the regulatory and legal ramifications of not being cautious in assessing cases of apparent misdiagnosis.

A general principle of oral squamous cell cancer management is that early detection results in increased survival and decreased morbidity. Delay to diagnosis occurs in all stages of oral cancer but is more frequently seen in single patients, non-smokers, and those with Stage IV (advanced) disease. With the increase in cases of oropharyngeal cancers related to human papilloma virus rather than tobacco abuse, it is likely that delay in getting these patients diagnosed will continue to be a problem. In a review of an institution’s database containing more than 26,000 oncology patients, delay to diagnosis could be divided into two parts: (1) primary delay, where the patient delays presenting to a healthcare practitioner; and, (2) secondary delay, where this first point of contact does not immediately diagnose the condition.

This present case details a situation in which a general dental practitioner failed to diagnose an odontogenic carcinoma, providing the patient with a diagnosis of aphthous ulceration. The patient did not keep all follow-up appointments and ultimately the condition progressed. Once the condition “declared itself” and became clinically obvious to the general dentist, he took photographs, radiographs, and ensured that the patient was seen immediately by an oral surgeon who equally quickly referred the patient into the provincial cancer system.

The patient ultimately complained to the Dental Regulatory Authority (DRA) and the dentist, without benefit of counsel or expert assistance, pled guilty to “failure to diagnose.” After he realized a long suspension was imminent, he retained a lawyer and an expert. This became problematic for all parties involved.

By reviewing the records of the case, the general community standard in diagnosing the far more common squamous cell cancer of the oral cavity, and undertaking a prospective study of 100 patients, the defense posited that the practitioner had not committed an error in this particular case. At this study’s institution, in the past 30 years more than 14,000 head and neck cancers have been treated in the clinic. Of these, precisely two were odontogenic carcinomas. The prospective study revealed the median time for patient-related delay to diagnosis and practitioner-related delay to diagnosis was approximately 5 weeks and 13 weeks, respectively. Furthermore, the patient, who later became a patient (and one of the two cases with this condition at this study’s institution), had successful management that was identical to the treatment the patient would have received had there been a prompt diagnosis weeks earlier. In the interim, the general dentist, presumably assuming he was not being diligent, had started taking biopsies of many variants of normal — unwittingly alarming a large number of otherwise well people.

Many issues came to bear in the defense of this individual including factual errors the defendant had previously agreed were true that were later found to be untrue and errors uncovered by the defense team. Despite the prior plea arrangement, the DRA, whose conduct was very reasonable throughout the process, recognized the importance of these new issues as well as information brought to the table by the defense and agreed to a grossly diminished penalty that was accepted by the dentist.

While failure to diagnose is not encouraged, it is important that experts realize that cancers must be of a certain size and exhibit clinical features that sufficiently raise the index of suspicion of the treating person. Additionally, it is prudent to retain competent legal advice and obtain the input of an expert in the field prior to entering into plea arrangements with DRAs or anyone else.

Oral Cancer, Misdiagnosis, Malpractice

Odontology Section - 2015

G55 Forensic Odontology (FOd) in the Canadian Armed Forces: FOd Activities Historical Review and Structure

Genevieve D.S. Bussiere, DMD, 2513 Sparrow Court, NW, Edmonton, AB T5S 0G7, CANADA*

After attending this presentation, attendees will understand, from a military viewpoint, the historical Forensic Odontology Disaster Victim Identification (FOd DVI) operations as viewed and experienced by military forensic dentists and auxiliary staff. These experiences include both domestic and international deployments. This presentation will present the challenges encountered and techniques used to overcome these challenges and will also present an overview of the Canadian Armed Forces Royal Canadian Dental Corps' FOd standards, training, and response capacity in the context of the Geneva Convention, North Atlantic Treaty Organization Standardization Agreement (NATO STANAG) 2464, and American, British, Canadian, and Australian (ABCA) requirements. The organization and evolution of the Canadian Forces Forensic Odontology Response Team (CF FORT) will be outlined and discussed.

This presentation will impact the forensic science community by increasing its situational awareness of the Canadian Armed Forces' (CAF) FOd capabilities and contributions; CAF lessons learned may influence future DVI responses.

This presentation will be an information overview of the Canadian Armed Forces (CAF) Royal Canadian Dental Corps' FOd standards, training, and response capacity in the context of the Geneva Conventions, NATO STANAG 2464, and ABCA requirements. The organization and evolution of the CF FORT will be outlined and discussed. This presentation will explain the origins of the team's composition and establishment and the different elements that are taken into consideration in preparing the team members to respond to the unexpected, maintaining a 48-hour notice-to-move readiness level. Finally, partnerships and supporting professionals within the military and civilian community will be acknowledged.

Participants will gain a military perspective by being presented with historical FOd DVI operations as are permitted to be shared, viewed, and experienced by Canadian Armed Forces military dentists and auxiliary staff. These experiences include domestic operations in support of provincial coroners/medical examiners working in collaboration with the Royal Canadian Mounted Police (RCMP) (i.e., Swiss Air Flight 111 and First Air Flight 6560) and international deployments and operations (i.e., identification of fallen soldiers in Afghanistan and actual support to international operations in collaboration with the Canadian Department of Foreign Affairs, Trade, and Development and the RCMP). Discussion will touch on the uniqueness of each response from the coordinated adaptation, including their analysis of the working environment, political expectations, response delay afforded, and the expected team composition and restrictions despite recognized standards.

This presentation will present the challenges encountered during each FOd involvement and techniques used to address/overcome them. Solutions found to address issues such as dealing with policy expectations, the requirements for transport and maintenance of equipment, working conditions, credentialing, dental documentation-evidence handling, responders' readiness level, training, physical and mental health well-being, communication, safety, and the documentation of lessons learned will also be discussed.

The contribution and challenges faced by CF FORT to the ongoing efforts put forth by the Canadian Armed Forces' Department of History and Heritage with the identification of recently recovered remains of our fallen World War I, World War II, and Korean War military members will also be discussed.

This presentation will give an overview of future considerations with an emphasis on the need for continued military and civilian community collaboration in standing together, ready to provide professional and timely support to DVI operations in all environments.

Canadian Armed Forces, Forensic Odontology, CF FORT

Odontology Section - 2015

G56 Odontology Support for Humanitarian Events

James P. Fancher, DDS, PhD, 345 Blue Lane, PO Box 682, Martindale, TX 78655*

After attending this presentation, attendees will understand the role of the odontologist in supporting humanitarian events.

This presentation will impact the forensic science community by providing an analysis of the results of postmortem dental examinations for undocumented border crosser deaths in South Texas. The role of the odontologist as a team member with forensic anthropologists will be emphasized.

The traditional role of the odontologist in mass disaster and humanitarian events is to provide identifications of deceased individuals by comparing antemortem and postmortem dental records. In many humanitarian events, such as natural disasters and cases of genocide, standard postmortem dental records can be completed on recovered human remains, but antemortem dental records often either do not exist or are difficult to locate and collect. In spite of impediments to traditional identification methods, the odontologist can provide critical information that will help narrow the search among a group of missing and unidentified individuals or will possibly lead to positive identifications.

Documentation of individual dental traits, age estimation, dental disease status, restorative characteristics, cultural accoutrements, and oral/facial trauma can contribute to building a biological and cultural profile that will help narrow the search for an identity. The odontologist may help provide enough evidence to narrow the search for an identity, exclude a potential match from existing data bases, or complete a positive identification. Additionally, DNA evidence for identification may also be provided by sampling an entire tooth or its pulpal contents. The trained odontologist is the logical choice to select teeth and perform pulp extirpations for DNA analysis.

Cases from Operation Identification (OpID) are used to illustrate the role of the odontologist in work that focuses on identifying undocumented border crosser deaths in the Rio Grande Valley of South Texas. These cases are the complete set of cases examined at one forensic anthropology center (Texas State University). Nearly all cases examined have full or nearly full dentitions. Existing dental treatment in 28% of the cases suggest that dental records may exist. Dental age estimations have been completed for 38% of the cases, with all the cases in good agreement with other anthropology age estimation techniques. Cultural characteristics of anterior restorations have been recorded that contribute to the profile of 14% of the cases. Untreated caries and periodontitis affect the majority of cases in highly variable degrees. Antemortem facial traumas, including fractured nasal structures and other facial bones, have also been recorded.

In conclusion, this analysis of dental data from a group of unidentified remains shows that the odontologist has had an important role in building the biological and cultural profile of sample cases from OpID. All work has been completed with the odontologist being a member of a forensic anthropology team. Even though definitive identifications by dental methods may be few, the detailed dental profile is a positive contribution to the work of the identification team. The dental profiles have helped narrow the search among missing individuals and have excluded potential matches from the National Missing and Unidentified Persons System database. The traditional methods of identification may need to be redefined to include the contributions of methods that refine searches.

Odontology, Humanitarian Identification, Operation Identification

G57 Restoring Smiles for Victims of Domestic Violence

Helena Soomer Lincoln, DDS, PhD, 714 W 20th Avenue, Spokane, WA 99203*

After attending this presentation, attendees will understand the effectiveness by which victims of domestic violence can recover their smiles.

This presentation will impact the forensic science community by providing resources to victims of domestic violence on how to restore their smiles in the most effective and economical way possible.

This presentation demonstrates an immediate solution to victims' problems when teeth are broken and lost as a result of domestic violence or assault. Assault victims frequently present with facial injuries, including trauma to the oral cavity and teeth. Loss of teeth results in not only physical and emotional trauma, but loss of integrity and confidence as well. Confidence is closely tied to the ability to speak and smile, both of which are severely affected by damage and loss of teeth.

Initial patient examination includes review of chief complaint, history of present illness, and imaging studies (panoramic X-ray, clinical photos, etc.), followed by physical examination and establishing diagnosis. First aid is given if necessary.

The following is a description of how effectively dentists and on-site laboratory technicians can work together in restoring the smile of an assault victim in a matter of few hours.

Alginate impressions are taken, poured up, and bite registration is completed. If broken, unrestorable teeth are present, these are ground off of the model, and a clear surgical stent is fabricated, then set aside for surgery. The models are trimmed and articulated with bite verification while the patient is in the chair. The mold and shade of new denture teeth are selected chair-side for the patient. These newly selected denture teeth are now set in wax on the models and wax try-in completed verifying proper esthetics, phonetics, and function with the patient. After the patient and dentist approve the setup of the teeth, the waxed denture borders are warmed up in preparation for border molding. A final impression is then made of the border-molded, waxed denture. Next, the impression is poured up and the dentures are immediately flasked and processed with a hydrocolloid processing technique, then trimmed and polished for delivery.

At the same time, the patient is locally anesthetized with 2% lidocaine and 1:100,000 epinephrine using a painless injection technique for extractions of broken and unrestorable teeth, as well as an alveoloplasty procedure or any other required preprosthetic surgery; unrestorable teeth are then extracted. A surgical stent is used during alveoloplasty, sutures are placed, and dentures are placed immediately. Patients leave smiling, often crying from happiness and excitement, and with regained confidence!

The technique described here can be used as a removable partial denture, implant retained partial denture, or full denture fabrication. If dental trauma is less severe and teeth are restorable, operative dentistry or fixed prosthodontics should be used. The key is to provide an immediate solution for the victim in order to restore their confidence and their smile!

Violence, Abuse, Smile

G58 The Implications of a Guilty Verdict for an Innocent Defendant

John P. Demas, DDS, 8814 Fort Hamilton Parkway, Brooklyn, NY 11209*

After attending this presentation, attendees will better understand the difficulties facing an innocent defendant in establishing innocence after having been deemed guilty.

This presentation will impact the forensic science community by explaining how a guilty verdict changes the dynamic for a defendant and how difficult it is to reverse a wrongful conviction.

Under the United States criminal justice system, there is (in theory) a presumption of innocence of the accused. What citizens have been told is that they are innocent of the charge until proven guilty. If it has been determined that a case should proceed to trial, the prosecutor is tasked with proving guilt beyond a reasonable doubt; however, the duty of the prosecutor is to seek justice, not merely to convict. It is not (or at least it should not be) incumbent upon a person to prove his or her innocence.

The American legal system, based originally on English common law, is an adversarial system. As such, the parties to the case, the state, and the defendant rely upon their respective advocates, the prosecutor and the defense attorney, to put forth their case. The presentation of evidence is governed by sets of procedural rules as interpreted by the trial judge and some evidence may be proscribed either because of its provenance or because of procedure.

Should a jury return a guilty verdict for a defendant who is, in fact, innocent of the crime with which they have been charged, the path to the truth may be so encumbered that justice is never served. A guilty verdict changes the dynamic for a defendant who is now, in the eyes of the law, the guilty party. Reversing a wrongful conviction is a slow, difficult exercise.

The process is not a simple presentation of facts or recitation of testimony which will result in the exoneration of the innocent. In fact, exculpatory evidence may never be presented at trial and attempts to correct a wrong and present such evidence before the trier of fact might be opposed and thwarted at every turn, post conviction. Additionally, some members of the forensic community may believe that should they, as experts, be presented with additional facts or information regarding a case in which they have testified and should such facts cause them to change their opinion, that they can simply present such revised opinion to the bench, it will be admitted, and justice will be served. It is not so.

When seeking post-conviction relief on the grounds of either manifest injustice or absolute innocence, the burden of proof is now tasked to the convicted individual. He or she must argue that a due process violation occurred or, in states which allow post-trial relief on the basis of newly discovered evidence, that said evidence “makes a different result probable on retrial.”¹ Without considerable resources on the other side of the prison walls (in the form of finances and earnest and dogged legal representation), it is not unreasonable to suggest that this task might well be beyond the means of most convicted individuals.

Guilty Verdict, Wrongful Conviction, Post-Conviction Relief

H1 An Autopsy Report: Death Secondary to a Widely Disseminated Invasive Scopulariopsis Infection

Ross James Miller, MD*, Jackson County MEO, 660 E 24th Street, Kansas City, MO 64108; Sean Abbott, PhD, Natural Link Mold Lab, Inc, 4900 Mill Street, Ste 3, Reno, NV 89502; Connie F.C. Gibas, PhD, University of Alberta, Highway 60, Edmonton, AB T6G 2E1, CANADA; Marius Tarau, MD, 660 E 24th Street, Kansas City, MO 64108; Mary H. Dudley, MD, Jackson County MEO, 660 E 24th Street, Kansas City, MO 64108; and Peter C. Iwen, PhD, University of Nebraska Medical Center, 985900 Nebraska Medical Center, Omaha, NE 68198

After attending this presentation, attendees will be aware of this clinically rare fungus causing disseminated infection and death in an immunocompromised host. Attendees will know that apart from culture-based methods and morphology, there are additional molecular-based methods that are able to provide more exact identification of offending organisms. This presentation also provides an opportunity to add to the body of literature relating to this specific species.

This presentation will impact the forensic science community, in particular the general pathology community, by alerting them to the various options available to them for organism (in this case fungal) identification in cases of infectious death.

Introduction: *Microascus* species and their *Scopulariopsis* anamorphs are fungi common in the environment, but rarely associated with invasive disease. This report describes a case of disseminated infection caused by *Microascus cirrosus* and compares this case with those previously reported in the literature.

Case Report: A 46-year old woman developed graft versus host disease of the gastrointestinal tract and multiple episodes of bacterial sepsis following both autologous and allogeneic stem cell transplants for non-Hodgkin's lymphoma. The patient died after rapid onset respiratory failure. Postmortem examination showed multiple white-tan deposits associated with surrounding hemorrhage and tissue necrosis in the heart, right lung, bilateral kidneys, thyroid, lymph nodes, and brain. The histologic correlate to these gross findings was an invasive infection by a fungus with septate hyphae and associated with abscess formation and angioinvasion. Postmortem cultures from right lung tissues revealed a darkly pigmented *Scopulariopsis* species. Subsequent phenotypic analysis of the isolate cultured on cellulose agar demonstrated the characteristic ascocarp and ascospore morphology typical of *M. cirrosus*. Identification was confirmed by a 100% sequence similarity to the ex type strain of *M. cirrosus* UAMH 9389 using the D1D2 domain of the nuclear large subunit ribosomal DNA gene region.

Results: Thirty-five cases of invasive infection caused by *Microascus* (*Scopulariopsis*) species have been reported in the literature with three caused by *M. cirrosus*. The species in all three cases were identified by observation of the mature ascomata with two of the cases confirmed by sequencing of the LSU D1/D2 gene region. Similar to the present case, one of the prior cases was also characterized by the formation of fungal abscess in the tissues and angioinvasion in another case.

Conclusion: This report expands the conditions associated with invasive *Microascus* (*Scopulariopsis*) infection and provides an opportunity to describe methods that can be useful in species identification.

Scopulariopsis, Microascus, Fungal

Pathology/Biology Section - 2015

H2 Incidence and Distribution of Intracellular Fat in Cardiac Myocytes in Chronic Alcoholics

Amy Deibler, Shady Grove Adventist Hospital, Dept of Pathology, 9901 Medical Center Drive, Rockville, MD 20850*

The goal of this presentation is to show the results of research describing the incidence of a change that can be seen in the cardiac myocytes of chronic alcoholics: the accumulation of intracellular neutral lipids.

This presentation will impact the forensic science community by suggesting that the presence of intracellular lipids in cardiomyocytes could serve as histologic evidence for a cause of death in chronic alcoholics in the absence of other pathologic findings at autopsy.

Chronic alcohol intake in some patients produces a congestive type of cardiomyopathy. Pathologically, alcoholic cardiomyopathy is manifested as cardiomegaly and biventricular dilatation. Microscopic sections of severely affected hearts show fibrosis. This investigation describes the incidence of intracellular lipids, a change that can be seen even earlier in alcoholic heart disease.

The objective of this research was to determine whether there is a significant increase in lipid accumulation in postmortem samples of myocardium from chronic alcoholics. The case material used in this study was obtained from 26 hearts of patients who were known to have histories of chronic, excessive alcohol consumption. These patients were autopsied at the University of Maryland Medical Center, the Baltimore VA Medical Center, and the Office of the Chief Medical Examiner for the State of Maryland. Hearts obtained from 35 autopsy patients at the University of Maryland Medical Center with no history of alcohol abuse served as the random control population.

Samples were obtained from the myocardium at the time of autopsy from the posterior right ventricle, the left ventricle, and the intraventricular septum. A modified Oil-Red-O stain was used to determine intracellular lipid droplets. The subjective intensity of lipid deposition was graded in terms of an arbitrary scale 0 to 5+ (0=no lipid, 5+=total replacement of the myocyte by lipid). Electron microscopy was performed on selected cases to confirm the light microscopic observations.

Microscopic examination of Oil-Red-O-stained sections of heart muscle showed that 13 of the 26 alcoholic hearts chosen had increased amounts of lipid in the myocardium, predominantly in the right ventricle. In no case was alcoholic cardiomyopathy diagnosed on a clinical basis, although gross examination of the heart in a few cases indicated the possibility of the presence of this disease. In two alcoholic cases, lipid distribution was widespread. In both cases, the cause of death was not clear cut. In the non-alcoholic population, seven of the 35 hearts showed evidence of intracellular lipid deposition. Of these seven patients, six had documented histories of treatment with chemotherapeutic regimens, a known cause of intramyocardial fat. Statistical comparison between the two study populations was calculated by the Chi-square test and gave a significant value of p less than 0.05.

The findings in this study suggest that intracellular lipid deposition may reflect occult alcoholic cardiomyopathy of varying severity, especially in the absence of other known causes of intramyocardial fat, such as prolonged anemia and chemotherapy. The lipid deposition observed in this investigation appears to be a sub-lethal, covert insult to the myocardium which precedes or predisposes to the overt symptoms of alcoholic cardiomyopathy. The finding of lipid-laden cardiac myocytes may also suggest the possibility of sudden/toxic metabolic cardiac death in alcoholics where no other significant or lethal pathologic findings are documented at autopsy.

Cardiac Myocytes, Alcoholic Cardiomyopathy, Alcoholism

H3 Congenital Valsalva Sinus Aneurysm Causing Sudden Unexpected Death in a 20-Year-Old Woman

Selly R. Strauch, MD, University of Mississippi Medical Center, 2500 N State Street, Jackson, MS 39216; Charu Subramony, MD, University of Mississippi Medical Center, 2500 N State Street, Jackson, MS 39216; and Brooke Sims, MD, University of Mississippi Medical Center, 2500 N State Street, Jackson, MS 39216*

After attending this presentation, attendees will understand the importance of considering an acquired or congenital cardiovascular disorder as an etiology in sudden and unexpected death.

This presentation will impact the forensic science community by increasing awareness of the possibility of congenital cardiac disorders presenting with a range of clinical symptoms as the cause of sudden and unexpected death.

This is a rare case in which a young woman with recently diagnosed Acute Myeloid Leukemia (AML) presents with a pericardial effusion and dies suddenly as a result of a cardiac tamponade secondary to a rupture of a congenital right Valsalva sinus aneurysm.

A 20-year-old woman with high-grade Myelodysplastic Syndrome (MDS) was admitted to the hospital due to increasing respiratory distress. Her MDS converted to AML. While being treated with chemotherapy, imaging studies revealed a significant pericardial effusion. Magnetic resonance imaging revealed a massive chronic lobulated pericardial effusion. Cardiac magnetic resonance imaging was performed and revealed a large sinus of Valsalva aneurysm involving the ostium of the right coronary artery. The pericardial effusion occupied one-third of the chest volume and was composed of septations extending from the epicardium to the pericardial wall.

At autopsy, opening of the thoracic cavity revealed a distended pericardial sac containing a 3.0cm thick, yellow-red, encircling layer of partially clotted blood. Both the pericardial sac and epicardial surface of the heart were firmly adhered to the partial clot. The weight of the heart, including the hemopericardium was 1,340gm. Examination of the heart and great vessels revealed a 3.8x2.7x2.5cm partially clotted blood-filled cavity extending 1.0cm below the right coronary artery ostium (the right Valsalva sinus), through the interventricular septum, and into the wall of the left ventricle. This cavity perforated into the right ventricle; however, the thick adherent hemopericardium made it difficult to find the exact perforation defect. This cavity was associated with a tortuous aneurysm which bulged into the right ventricle below the tricuspid valve and into the left ventricle. The right aortic cusp was torn midline from the base. Microscopy of the lesion revealed dense collagen without the aortic elastic layers, as well as erythrocytes, acute inflammatory cells, hemosiderin laden macrophages, and layers of fibrin deposits, consistent with an organizing thrombus and recent hemorrhage.

The majority of natural causes of sudden and unexpected death are due to a cardiovascular disorder. These disorders include arrhythmias, ischemic heart disease, aortic stenosis, pulmonary embolism, and a rupture of a myocardial infarct.^{1,2} Congenital cardiovascular malformations are rare and can cause a rupture that leads to a hemopericardium. One rare lesion is an aneurysm of the sinus of Valsalva.

Aneurysms of the Valsalva sinus can be acquired through trauma, degenerative disease, or endocarditis of the aortic valve.¹⁻³ Congenital aneurysms of the Valsalva sinus are rare, although more common than their acquired counterpart and may be associated with a ventricular septal defect.^{1,3,4} There is a 3:1 male predominance and the individual is usually asymptomatic until adulthood.^{1,4} This aneurysm results from separation of the aortic media and the aortic valve cusp. This separation is due to the variable thickness of the collagen creating discontinuity, which can dilate, expanding into the cardiac septum or chamber.⁴ More than two-thirds of these aneurysms occur in the right aortic sinus, while 25% and 8% involve the posterior and left aortic sinuses, respectively.^{1,4}

Approximately 75% of individuals with a congenital aortic sinus aneurysm experience complications, with rupture of the aneurysm being the major complication.¹ The mean age the aneurysm ruptures is 31 years.^{1,2,4} Aortic sinus ruptures can involve more than one coronary artery. Ruptures may be large and acute or small and progressive, adding to the diversity of the clinical presentation.³⁻⁵ Surgical repair is often curative, as patients usually die within a year if they don't receive treatment.⁴

The range of clinical symptoms makes aneurysms of the Valsalva sinus difficult to detect. Because of this aneurysm's rarity, it often doesn't make the list of differential diagnoses. An individual may not be aware of having this condition, increasing the chances of being engaged in everyday activities when the aneurysm ruptures. The elusive nature of the condition will most likely result in a sudden and unexpected death requiring the examination of a forensic pathologist.

H4 Usability of Immunohistochemistry in Forensic Pathology

Iana Lesnikova, MD, PhD, Havkaertofte 14, Tilst 8381 8381, DENMARK; Marc Niclas Schreckenbach, RWTH Aachen University Hospital, Pauwelsstraße 30, Aachen, GERMANY; Liv Lindegaard Papanikolaou, MSc, Institut of Forensic Medicine, Brendstrupgårdsvej 100, Aarhus N, DENMARK; Maria Pihlmann Kristensen, MD, Institut of Forensic Medicine, Brendstrupgårdsvej 100, Aarhus N, DENMARK; and Stephen Hamilton-Dutoit, Institut of Pathology, Aarhus University Hospital, Noerrebrogade 44, Aarhus C, DENMARK*

After attending this presentation, attendees will better understand the usability of Immunohistochemistry (IHC) in forensic pathology.

This presentation will impact the forensic science community by providing information concerning how decomposition and the time between death and the autopsy affect the usability of diagnostic IHC in forensic samples.

IHC is an important diagnostic tool in surgical pathology but has limited use in forensic pathology. It is the general opinion that proteins degrade rapidly in devitalized tissues, decreasing the usefulness of IHC. The purpose of this study was to examine how the time since death affects the ability to carry out IHC analyses on forensic tissue samples.

Cases for this study were selected on the basis of the elapsed time from death to autopsy. The cases were allocated to one of the four groups (A to D) defined as: (1) Group A included cases autopsied shortly after death (one to three days) with no macroscopic signs of body decay; (2) Group B cases were autopsied three to seven days after death with signs of body decomposition such as green discoloration of the skin, marbling of the vasculature, swelling, gaseous distention, and skin slippage; (3) Group C cases were autopsied 7-14 days after death with marked swelling, black discoloration of the skin, moist and gas-ridden soft tissue, and some skeletonization and mummification of the bodies; and, (4) Group D were autopsied more than two weeks after death and the bodies typically displayed skeletonization and mummification. All the bodies (groups A-D) were found inside buildings, which in Denmark are normally heated to room temperature.

Formalin-fixed paraffin-embedded tissue samples were collected from 37 bodies and consisted of: (1) 37 samples of liver tissue — group A (10), B (10), C (8), and D (9); (2) 35 samples of lung tissue — group A (10), B (8), C (9), and D (8); (3) 16 samples of brain tissue — group A (10), B (3), and C (3); and, (4) 35 samples of muscle tissue — group A (10), B (7), C (10), and D (8). Tissue Microarrays (TMA) were constructed and IHCs were performed using an automated stainer.

The quality of TMAs and the degree of histologic changes following autolysis were evaluated using light microscopy of hematoxylin-eosin stained sections. The degree of autolysis of lung and liver samples were scored from grade 1 to grade 5 according to the degree of nuclear destruction: normal nucleus (grade 1); karyolysis and pyknosis (grade 2); karyorrhexis (grade 3); no nucleus visible (grade 4); and, no cell visible (grade 5).

The sections were stained with anti-KL1, anti-S100, anti-vimentin, and anti-CD45 antibodies, which are commonly used as a primary antibody panel in cancer diagnostic. The evaluating scoring protocol was positive (moderate or strong nuclear and cytoplasmic staining of more than 90% of cells) and negative (no staining or very weak staining in less than 10% of cells).

A good correlation between the postmortem interval and the degree of histological changes was found in all tissue samples (lung, liver, brain, and skeletal muscle). Strong positive staining of bile duct epithelium using anti-KL1 antibody was found in eight of ten samples (80%) of group A and no samples of group B-D. The staining of glial cells and myelin in brains with anti-S100 antibody was found in ten of ten samples (100%) of group A, three of three samples (100%) of group B, and three of three samples (100%) of group C. The staining of lymphocytes and kupffer cells with anti-CD45 antibodies was found in 36 of 38 (95%) samples of group A, 25 of 28 samples (89%) of group B, 21 of 30 samples (70%) of group C, and 15 of 25 samples (60%) of group D. The staining of endothelium with anti-vimentin antibodies was found in 36 of 40 samples (90%) of group A, 6 of 28 samples (21%) of group B, 1 of 32 samples (3%) of group C, and no positive staining in group D.

The data showed that IHC staining can be used, with some limitations, in forensic tissue samples. The IHC staining of bile duct epithelium in liver with anti-KL1 antibodies was positive in 80% of samples within three days after death, while the staining of lymphocytes with anti-CD45, myelin, and glia with anti-S100 antibodies, and endothelium with anti-vimentin antibodies were positive for an even longer time after death.

H5 Death Due to a Congenital Vascular Anomaly of Pulmonary Hamartoma Type: Malpractice or Tragic Fatality?

Mariela Marrone, MD, p.za G. Cesare, 11, Bari 70124, ITALY; Francesca Tarantino, MD, p.za G. Cesare, 11, Bari 70124, ITALY; Alessio Ostuni, MD, Section of Criminology, Policlinico of Bari Italy, P.zza Giulio Cesare 1, Bari 70124, ITALY; Andrea Marzullo, piazza Giulio cesare, n.11, Bari 70124, ITALY; and Francesco Vinci, MD, p.za G. Cesare, 11, Bari 70124, ITALY*

After attending this presentation, attendees will understand more about the relevant role of forensic investigation in medical liability evaluations.

This presentation will impact the forensic science community by serving as a case study in which it was possible to attribute a patient's death during a routine medical procedure to a rare disease rather than to the medical procedure as had been previously thought.

The goal of this study is to comprehensively characterize relevant forensic features, which may become important in resolving forensic cases.

In the legal medicine field, cases that seem straightforward can often hide rarities that can alter the results of the entire investigation. This can sometimes occur during malpractice investigations. In such circumstances, apart from the normal individual variables, the fatal outcome of a medical procedure may be due to a rare disease that is difficult to diagnose and whose evolution may be difficult to predict.

A case is reported of a 49-year-old man who died in a hospital due to a pulmonary hemorrhage during an instrumental examination (bronchoscopy) performed to define a previously identified mass in the right lung. The magistrate required an autopsy to evaluate whether the doctor who had performed the bronchoscopy was liable for malpractice.

Examination of the cadaver revealed a marked anatomical alteration of the right lung, which was much smaller in size and volume than the left lung. The entire parenchyma showed a denser consistency. Opening of the trachea and bronchi revealed the presence of many blood clots bilaterally. Moreover, in the proximal portion of the right bronchus, immediately before the bifurcation, a dense, congested capillary network was evident on the endoluminal surface. In addition, on the external surface between the superior and the medial right bronchi, a mass could be seen, not protruding into the lumen but with a rich vascularization, that was partially fused to the bronchial wall. Accurate macroscopic examination of the right lung (after fixation in formalin) demonstrated a thick tangle of vessels in the cricoid cartilage region, extending distally deep down to the level of the pericardial sac.

Histological examination demonstrated that the mass was not a tumor but a congenital vascular anomaly of the hamartoma type. This is a rare finding that, owing to its intrinsic morphologic-structural characteristics (tortuous vessels content, thin aneurysmatic walls), had lacerated simply in response to the rise in pressure induced by insertion of the bronchoscope in the bronchial tree, causing copious bleeding that led to the patient's death from asphyxia due to internal volume overload.

Before the cause of death had been determined, public opinion had unanimously attributed the death to medical error. A routine practice like bronchoscopy should not cause death; therefore, the doctor must have made a serious mistake. Fortunately, the autopsy not only demonstrated the cause of death but also revealed a rare congenital lung disease.

There is an increasing tendency to blame the doctor for medical failures; if this is not restrained, it will lead to "defensive" medicine, ultimately harming patients, overall.

This presentation will impact the forensic community by underlining the importance of forensic investigations and their correlations with anatomic-pathological findings.

H6 Adult Epiglottitis: A Case Series Review in an Autopsy Population

Maggie Bellis*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Jayantha Herath, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Michael S. Pollanen, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA

After attending this presentation, attendees will be informed of the incidence, presenting complaints, and postmortem and laboratory findings in cases of sudden death due to acute epiglottitis in adulthood. Attendees will also be aware of what the main differential diagnoses are and how to distinguish one from another based on history, autopsy findings, and laboratory studies.

This presentation will impact the forensic science community by bringing awareness to pathologists and forensic pathologists of how this disease has now shifted from being a disease of children to a disease of adults and that it can often present with sudden death. This presentation will hopefully make attendees aware of the characteristic history and presenting complaints in these types of deaths and will guide decisions in ordering specific postmortem ancillary tests in order to make the correct determination regarding the cause of death.

Objective: This study was conducted to gain insight into the incidence of deaths in adults from acute epiglottitis and characterize the population affected, presenting symptoms, gross and microscopic features, and to discuss the main differential diagnoses at autopsy.

Method: A retrospective review was performed on medicolegal autopsy cases within the province of Ontario, Canada, in which the cause of death was given as epiglottitis between the years 2001 and July 2014 inclusive. Demographic features, clinical history, gross and microscopic autopsy findings, and the results of laboratory investigations were described. In total, 11 cases were identified.

Results: The incidence of acute epiglottitis as a cause of death was 1 in every 8,000 cases, or just under one case per year. The mean age of decedents was 50 years with a male predominance. Three were smokers; the most commonly reported concomitant diseases were diabetes mellitus, hypertension, hyperlipidemia, and chronic obstructive pulmonary disease. The most common presenting symptoms were sore throat, dysphagia, and low-grade fever with duration of symptoms ranging from several minutes to three days. All decedents complained of sudden shortness of breath before collapsing, except for one unwitnessed case. Three decedents had initially been seen by a physician and discharged home on antibiotics with a diagnosis of Streptococcal upper respiratory tract infection, only to collapse shortly thereafter. Gross postmortem findings included hyperemia and edema of the epiglottis and aryepiglottic folds with occasional swelling of the glottis and airway narrowing. Microscopy showed vascular congestion, stromal edema, and acute inflammation with a few cases also positive for the presence of stromal hemorrhages, abscess formation, and vasculitis. Five cases had positive blood and/or tissue cultures with a variety of organisms identified; Streptococcus was the predominant genus and in no case was *Haemophilus influenzae* isolated. Results from immunological tests performed in some cases were non-contributory.

Conclusions: Sudden deaths from acute epiglottitis in adults may be more common than previously appreciated. It should be kept in mind by forensic pathologists and hospital pathologists in cases of sudden death in which the presenting symptoms are consistent with an upper respiratory tract infection followed by an episode of acute shortness of breath. This study suggests taking blood and tissue cultures in cases with such a history in addition to serum for immunological testing to assist in differentiating the diagnosis when little more than a swollen epiglottis is identified at autopsy.

Epiglottitis, Adults, Autopsy

H7 Fatal Ice Cream: A Rare Case of Food-Induced Anaphylactic Shock

*Gabriela Perilli, MD**, Viale degli Aviatori 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; *Benedetta Di Battista, MD*, Viale degli Aviatori, 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; *Sara Vita, MD*, Viale degli Aviatori 1, Foggia 71100, ITALY; *Antonella Giuliani, MD*, University of Foggia, Dept of Forensic Pathology, viale degli Aviatori 1, Foggia 71100, ITALY; and *Stefano D'Errico, MD*, University of Foggia, viale degli Aviatori, Foggia 71100, ITALY

After attending this presentation, attendees will understand the importance of a complete methodological forensic approach in fatal cases suspected for anaphylaxis and the relevance of immunoserological investigation to detect IgE-specific response to allergens.

This presentation will impact the forensic science community by emphasizing the rarity of fatal food-induced anaphylaxis and the importance of carrying out an exhaustive immunohistochemical study with anti-tryptase antibodies and of measuring allergen-specific IgE in blood samples from the corpse to indicate sensitivity to certain allergens in order to obtain a reliable postmortem diagnosis of anaphylactic shock.

Food-Induced Anaphylaxis (FIA) is a serious allergic reaction that may rapidly cause death in otherwise healthy individuals. There is no universal agreement on its definition or criteria for diagnosis. According to international recommendation, a food-induced allergy is diagnosed when two or more of the following symptoms occur rapidly and acutely after exposure to a known allergen: acute onset of an illness (minutes to several hours) with involvement of the skin, mucosal tissue, or both (e.g., generalized hives, itching or flushing, swollen lips, tongue, or uvula, rhinorrhea, conjunctivitis); respiratory compromise (e.g., dyspnea, bronchospasm, stridor, hypoxia); and, cardiovascular compromise (e.g., hypotension, collapse). Food-induced allergy is generally sustained by an immunological mechanism which is often IgE-mediated or by alternative immune systems (such as other forms of antibodies, immune complexes, or T-sensitive lymphocytes). The epidemiology of food-induced allergy has been difficult to quantify, with estimates varying widely. Most surveys indicate that food-induced reactions account for 30% to 50% of anaphylaxis cases in North America, Europe, Asia, and Australia, and up to 81% of anaphylaxis cases in children; however, the precise incidence of fatal anaphylaxis cases due to people with food allergies remains unknown. Fatal food anaphylaxis is rare and represents only 0.1% of all cases. Although a wide range of foods have been reported as the cause of FIA, the most commonly implicated foods worldwide are peanuts, tree nuts, milk, eggs, sesame seeds, fish, and shellfish.

This presentation concerns a 16-year-old male who had a medical history of allergic asthma, celiac disease, and known food-induced allergies for fish, fresh milk, peanuts, hazelnuts, walnuts, apples, kiwis, and peaches. He immediately collapsed a few minutes after eating a Danish-style ice-cream sandwich. Advanced life support with intramuscular adrenaline and resuscitation maneuvers were unsuccessful. A complete postmortem examination was performed a few days after death. Gross examination was unremarkable, except for mild cerebral edema and white foam in the main bronchi. Lungs were normal in shape, increased in volume and weight, and exhibited small subplueral petechiae. Histological examination revealed polivisceral stasis, mild cerebral edema, and acute pulmonary edema mixed to acute pulmonary emphysema. Myocardial interstitial edema was also detected. An immunohistochemical technique was used to estimate the mast-cell population using the anti-tryptase antibody as a mast-cell specific marker. A great number of degranulating mast cells with extracellular tryptase-positive material were observed. The identification of positive CD3 (++) and CD8 (+) cells in the duodenal mucosa confirmed the diagnosis of celiac disease. Toxicological analysis on blood specimens was unremarkable. A serum concentration of mast cell tryptase from femoral blood was 41.4ug/l. Research of total and specific IgE for more common food allergens was performed showing high values for kiwi, wheat, peach, shell fish, and gluten. Wheat composition of the ice-cream sandwich was indicated as the cause of food-induced fatal anaphylaxis.

Food-Induced Allergy, Anaphylactic Shock, Allergen-Specific gE

Pathology/Biology Section - 2015

H8 Sudden Intrauterine Death Related to a Fork Bead Cord

Luisa Andrello, MD, Magenta Street 25/I, Olgiate Olona, Varese 21057, ITALY; Laura Della Chiesa, MD, Via Guicciardini 9 Bis, Varese, ITALY; Silvia D. Visonà, MD, Via Guicciardini 9 Bis, Varese, ITALY; and Antonio M.M. Osculati, MD, Via Meraviglia 22, Lainate, Milan 20020, ITALY*

After attending this presentation, attendees will be aware of the possibility of a sudden intrauterine death related to a bead cord abnormality.

This presentation will impact the forensic science community by explaining the rarity of a particular case and the relevance of autopsy and histological findings which resulted in a certain diagnosis of death.

A 29-year-old woman went to the hospital because of the onset of abdominal pain with initial intermittent contractions at 37 +5 weeks of pregnancy. Early clinical-instrumental investigations consisting of a medical appointment and cardiotocographic detection were found to be normal. Taking into consideration her imminent delivery date (a Caesarean was scheduled two days later), the woman, with her doctor's agreement, chose to stay at the hospital. In the afternoon (approximately 15 hours after her emergency room admission), cardiotocographic detection was repeated and confirmed to be normal. At that time, the fetus was alive and did not show any signs of distress. Doctors medicated the woman with a pain reliever and antibiotics in order to avoid the risk of fetal infections (vaginal swab for Group B Strep positive at 36 weeks). After a peaceful night, in the morning the woman stated she had not perceived fetal movements. A new cardiotocographic study demonstrated no fetal heartbeat, which was further confirmed by ultrasound. A lifeless female fetus of regular body development was removed by Caesarean section the same morning, revealing that the fetus was immersed in an amniotic fluid described as "bloody."

The public attorney requested an autopsy and histological examinations in order to exclude any medical responsibility. The main autopsy findings included bloody material in the nasal and oral cavity and the esophagus, the presence of bloody fluid in the stomach, and the almost complete absence of blood in the main vessels and the fetal heart. In the context of a paramarginal umbilical cord, an abnormality of the cord itself consisting of an accessory umbilical vessel that originated in the placenta, the umbilical cord was inserted after 15cm of free passage into the amniotic cavity. This implant is called a "fork." At the point of accessory vessel insertion into the placenta, there was a laceration of the vessel wall. Subsequent histological examination confirmed the presence of a vital laceration into the vessel accessory "fork" wall, corresponding to its placental implantation, with extensive blood infiltration of surrounding tissues. The remainder of the placenta was unremarkable and consistent with the stage of intrauterine development.

The cause of death was hemorrhagic shock resulting from the tearing of the accessory umbilical vessel characterized by the rare anatomical anomaly known as "furcate insertion" (insertion fork) of the umbilical cord. In the literature, such an atypical anatomical variant is among the rarest existing (about 0.1%). The possibility of rupture of this vessel, which occurred in the present case, can be determined by fetal movements, uterine contractions, or the overlap of the two mechanisms. For this reason, the rupture of these vessels occurs more frequently (although extremely rarely) during labor. The vessel rupture results in a rapidly fatal hemorrhage for the fetus. There are no obvious signs detected clinically nor are symptoms experienced by the mother, as blood pours into the amniotic cavity. The anatomical anomaly is usually not diagnosed before birth because specific ultrasound analysis of the conformation of umbilical cord is not performed routinely. Detection may only occur with an evaluation of the insertion and presence of physiological venous and arterial vessels through an dedicated ultrasound or, even better, an amnioscopia. This study notes only one similar case reported in the literature.

Fork Bead Cord, Sudden Intrauterine Death, Bead Cord Malformation

Pathology/Biology Section - 2015

H9 Death as a Consequence of an Intestinal Obstruction Due to an Abnormal Congenital Band in a 4-Year-Old Child

*Massimiliano dell'Aquila, MD**, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Aniello Maiese*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Serenella Serinelli, MD*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena 336, Rome, Lazio 00169, ITALY; *Lorenzo Gitto, MD*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; and *Luigi Bonaccorso, MD*, Forensic Sci Med Pathol, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome 00169, ITALY

After attending this presentation, attendees will understand the necessity of a correct autopsy technique when rare pathologies are discovered.

This presentation will impact the forensic science community by demonstrating the relevance of a solid technical skill when atypical findings are present at autopsy.

A 4-year-old child was found dead inside his home without any apparent cause. Questioning of his parents revealed that he had experienced an ill-defined increasing abdominal pain, which had started three days before his death and was associated with a high fever (37.7°C) and vomiting. The abdominal pain was treated with enemas of lukewarm water containing glycerin, paracetamol, and peridon. He had previously been healthy. External examination of the body revealed no injuries.

An autopsy was performed. Upon opening of the abdominal cavity, copious amounts of transudate mixed with blood were revealed totaling approximately 2,000cc. The small bowel loops were markedly distended and, in some sections, purplish-brown in color, suggesting necrosis. Part of the intestine was entrapped and strangulated by a fibrous band connected to the mesentery at four locations. The multiple occlusions resulted in the development of two non-contiguous areas of necrosis, one between the ileum and the ileocecal valve and the other extending from the lower third of the sigmoid colon to include the rectum.

Histological examination of the fibrous band showed connective tissue, with areas of ischemic necrosis at the level of the intestinal mucosa. Toxicological tests were negative. Death was due to intestinal obstruction and infarction caused by a congenital band. The obstruction and infarction resulted in dehydration and circulatory collapse.

An Abnormal Congenital Band (ACB) is among the multiple conditions that may cause an intestinal obstruction. ACBs are extremely rare and often manifest as intestinal obstruction, especially during childhood.^{1,2} The precise incidence of ACBs remain unknown, although studies have reported percentages varying from 1% to 3%.³ The etiology of ACBs are obscure and their locations include known embryogenic remnants, including the vitelline arteries and veins, and the omphalomesenteric ducts.⁴⁻⁶ The omphalomesenteric duct is an embryonic structure connecting the primitive bowel with the vitelline sac that disappears between weeks five and nine of fetal life. Incomplete regression may cause several types of congenital abnormalities, including Meckel diverticulum and entero-cutaneous fistula due to the persistence of the vitelline duct.

ACBs may originate from mesenteric anomalies. On approximately the 28th day of intrauterine life, the dorsal and ventral mesenteries transiently divide the peritoneal cavity into right and left halves; however, the ventral mesentery soon disappears, except around the liver and in front of the stomach. As the intestines assume their final positions, their mesenteries are pressed against the posterior abdominal wall. An ACB may therefore be a remnant of ventral mesenterium that failed to resorb completely.

Four types of congenital peritoneal bands have been described. In type 1, the cecum, which lies abnormally in the right upper quadrant of the abdomen, has a band called Ladd's Band, which extends across the second and third parts of the duodenum to the paravertebral gutter. Duodenal obstruction may therefore result from compression by Ladd's Band and/or from midgut volvulus. Type 2 bands extend from the hepatic flexure of the colon across the second part of duodenum to the right paravertebral gutter, causing duodenal compression at that site. Type 3 bands are hypertrophied hepatoduodenal ligaments, which obstruct the duodenum at the junction of its first and second portions. Type 4 bands are dense fibrous bands that bind the distal portion of the third part of the duodenum to the paravertebral fascia, causing extrinsic obstruction and always being associated with an incompletely rotated duodenum.

The child described in this study demonstrated a rare cause of death from intestinal obstruction due to an ACB. The band observed at autopsy could be traced back to the remnants of the omphalo-mesenteric or vitelline duct, indicating that it was a type 4 band.

In conclusion, clinicians should be aware of this entity as ACB may cause death in children.

H10 A Fatality Due to Type I Long QT Syndrome (LQTS) Associated With Electrolyte Abnormalities and Therapeutic Levels of Citalopram

*Dennis J. Chute, MD**, Dutchess County MEO, 168 Washington Street, Poughkeepsie, NY 12601; and *Robert J. Bready, MS*, Dutchess County MEO, 168 Washington Street, Poughkeepsie, NY 12601

The goal of this presentation is to review the relationship between Type I LQTS, dysrhythmia, and risk factors in teenagers.

This presentation will impact the forensic science community by presenting a case report of a lethal arrhythmia in Type I LQTS associated with blood levels of citalopram in the therapeutic range.

The acquired or inherited condition known as LQTS, defined by prolongation of the QT interval (the time interval from the start of cardiac ventricular depolarization to the completion of repolarization >480msec), is due to interference with normal myocardial repolarization.¹ It may cause ventricular fibrillation, Torsades des Pointe (TdP), palpitations, syncope, seizures, and sudden death. Presentation occurs at any age but childhood or early adulthood is typical. Inherited LQTS is due to 13 genetic mutations in ionic channel genes (channelopathies), most of which are dominantly inherited. Three genes make up the majority of cases (Types 1, 2, and 3). Type 1 is caused by mutations in the voltage gated potassium channel gene *KCNQ1* and is associated with arrhythmias during exercise or emotional stress. The heart usually appears grossly and microscopically normal in younger patients. Diagnosis depends on the clinical history, electrocardiogram changes, laboratory results, and a review of the patient's medication list. Known risk factors for TdP in these patients are: hypokalemia, hypomagnesemia, hypocalcemia, female gender, age over 60 years, and medications that block the potassium channel function.^{2,3} One such drug is the serotonin selective reuptake inhibitor citalopram; however, the blood levels needed to produce this side effect are debated.^{4,7} Of note, the Food and Drug Administration recently published a warning about citalopram used in higher doses.⁸

This study describes an 18-year-old female who collapsed and was found to be in ventricular fibrillation by paramedics. Just prior to collapsing, she was emotionally upset due to an argument with her boyfriend. After resuscitation, she converted to a sinus rhythm but developed prolonged seizures and expired from anoxic encephalopathy five days later. An admission electrocardiogram showed a corrected QT interval (Bazett's formula) of 648msec and serum chemistries revealed hypokalemia (2.9mEq/L) and hypocalcemia (7.6mg/dL, corrected). The reason for her electrolyte abnormalities was not identified. She had been taking 20-30mg of citalopram per day for depression; there was no history of hearing loss or sudden cardiac death in the family. The autopsy was unremarkable and her heart appeared structurally normal (337 grams). A postmortem blood sample submitted to GeneDx for genetic testing revealed a disease-causing missense mutation in the C-terminal end of the *KCNQ1* (R594Q) gene, a cause of Type 1 LQTS.^{9,10} This R594Q variant occurs within the assembly portion of the *KCNQ1* protein. An admission blood sample analyzed by National Medical Services Laboratories had a citalopram level of 120ng/mL. Reported premortem therapeutic levels are in the 40-100ng/mL range. Reported incidental postmortem ranges for this drug vary but are slightly higher: 400ng/mL, 90-760ng/mL, a median of 300ng/mL, 90-1,300ng/mL.¹¹⁻¹⁵ Lethal levels for this drug are usually much higher.¹⁶ The cause of death was attributed to a cardiac arrhythmia associated with the LQTS and electrolyte abnormalities. The contribution made by citalopram toward the initial dysrhythmia remains speculative but given the FDA warning about citalopram and TdP at higher doses, it is difficult to dismiss its role entirely as some would suggest.^{7,17,18} The case raises the question: Should clinicians screen for LQTS with an electrocardiogram before starting females on citalopram?

In summary, this was a case of inheritable LQTS in a teenager with risk factors for the development of ventricular dysrhythmias, including hypokalemia, emotional stress, and female gender. She was also on a medication previously associated with development of TdP, although typically at higher doses than prescribed. What contribution it made is uncertain. This report adds to the literature on citalopram blood levels in cases associated with the inheritable LQTS.

Arrhythmia, Long QT Syndrome, Citalopram

H11 **A Case of Lethal Idiopathic Plasmacytic Lymphadenopathy With Polyclonal Hypergammaglobulinemia: A Medical Challenge for the Forensic Pathologist**

*Giancarlo Di Vella, MD, PhD**, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY; *Oronzo Schiraldi*, University of Bari, Sez Med Legale Policlinico, Bari 70100, ITALY; *Lucia Tattoli, PhD*, Sezione di Medicina Legale, University of Bari, Bari, ITALY; and *Biagio Solarino, PhD*, Università degli Studi di Bari, Sezione di Medicina Legale, P.zza Giulio Cesare, 11, Bari 70125, ITALY

After attending this presentation, attendees will understand that the pathophysiology of Idiopathic Plasmacytic Lymphadenopathy (IPL) is not elucidated sufficiently and further clinical, histological, and immunological studies will be required in the forensic field, especially when medical malpractice is suspected.

This presentation will impact the forensic science community by reporting an uncommon case of lethal IPL with polyclonal hypergammaglobulinemia and renal failure in a young woman in which other differential diagnoses such as collagen, autoimmune, and infectious diseases were ruled out when she was still alive.

IPL was first described by Mori et al. in the early 1980s as a new disease entity resembling the plasma cell type of Castleman's Disease (CD). Both have multicentric lymphadenopathy, prominent polyclonal hypergammaglobulinemia, elevated erythrocyte sedimentation rate, elevated serum interleukin-6 (IL6) concentration, bone marrow plasmacytosis, and various abnormal laboratory data. Nevertheless, CD usually has an aggressive and fatal outcome associated with infectious complications or malignant tumors. IPL has a clonal B-lymphocyte proliferation producing high levels of immunoglobulin and/or their chains which affect the entire body. The clinical features are polymorphic because of the involvement of several organs (skin, and pulmonary, digestive, and renal systems). IPL can be asymptomatic for a long time but can exhibit an unexpected and rapidly fatal course. The treatment of IPL has not yet been established, but the efficacy of corticosteroid treatment, anti-cancer chemotherapy, and monoclonal antibodies has been indicated. Even though IPL is reported in literature, it is rarely recognized clinically and is often first diagnosed after the patient's death as a medical examiner's case for the forensic pathologist, who has to include it in the differential diagnosis of other diseases when medical malpractice is suspected.

This study reports the case of a 40-year-old woman admitted to the emergency room with acute renal failure and hypergammaglobulinemia. She had previously had frequent otitis, pharyngitis, and a poorly defined rheumatic disease. In the last month, she received antibiotics for bronchitis. Multiple myeloma was first suspected. The patient rapidly developed back pain, pericardial effusion, generalized pruritic rash of the face and trunk, splenomegaly (with no liver and lymph node enlargement), and finally coma (after six days). Bone marrow biopsy showed polyclonal plasmacytosis. Multiple myeloma was ruled out as well as infection, collagenopathy, and coagulopathy; therefore, a hypergammopathy due to a proliferative hematological malignancy was suspected. Despite medical efforts, the woman expired nine days after admission. A medicolegal autopsy was performed because of the lack of a diagnosis. The external examination of the body was negative. The autopsy showed brain swelling, pulmonary congestion, pleural adhesions, and hepato-splenomegaly. Histological examination of lymph nodes showed diffuse infiltrates of plasma cell and lymphocytes with features of erythrophagocytosis. Immunohistochemical staining confirmed plasma cells (CD138+) with a prevalence of kappa-positive cells, B (CD20+) cells, and T (CD3+) cells. Kidneys showed advanced glomerulosclerosis containing similar infiltrates. Toxicological analyses were negative. The final cause of death was multiple organ failure due to IPL with polyclonal hypergammaglobulinemia and advanced renal failure. The rapid worsening of the patient's condition did not allow the physicians to make the correct diagnosis. This case was particularly notable for the renal complications resulting from glomerulosclerosis and interstitial infiltration. The exact mechanisms of renal damage in IPL have an unknown etiology. It is supposed that an overproduction of IL6 induces proliferation of mesangial cells and interstitial infiltration of plasma cells. The process can be increased by paracrine or autocrine IL-6. No systematic evaluation of treatment regimens is available because much remains to be discovered about IPL. Possible medical liability associated with failure to diagnose and treat IPL deserves discussion.

IPL, Hypergammaglobulinemia, Autopsy

H12 Sudden Death Due to Drug-Induced Vasculitis

*Abdulrezak M. Shakir, MD**, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; *Jennifer Janssen, MS*, Allegheny County MEO, 1520 Penn Avenue, Pittsburgh, PA 15222; and *Todd M. Luckasevic, DO*, Allegheny County ME, 1520 Penn Avenue, Pittsburgh, PA 15222

After attending this presentation, attendees will understand that levamisole-induced vasculitis can affect the heart and lungs and can cause sudden death.

This presentation will impact the forensic science community by emphasizing the seriousness of levamisole vasculitis of the heart and lungs which can result in sudden death.

Introduction: Levamisole is a veterinary antihelminthic drug previously used in humans to treat nephritic syndrome and various autoimmune disorders. In 1999, levamisole was withdrawn for human use by the FDA due to its adverse effects including vasculitis. During the last decade, levamisole appeared as an adulterant in cocaine and various complications are reported in living individuals due to its vasculitis that affected the skin, kidneys, and skeletal muscles.

Case Presentation: A 49-year-old man was discovered dead during a welfare check. He was last spoken to by his mother three days earlier and his only complaint was that he felt cold. He was found at the bottom of the stairs, face down and unresponsive on the basement floor. The deceased was an unemployed laboratory worker who previously worked in a research laboratory and lost his job approximately four years earlier.

Autopsy revealed superficial blunt force trauma of the face and a localized subarachnoid hemorrhage of the right temporal lobe. Otherwise the autopsy gross findings demonstrated no significant evidence of a cause of death. Microscopy revealed eosinophilic vasculitis of the intraparenchymal vessels of the lungs with acute and organizing alveolar injury. The heart showed intramural eosinophilic vasculitis and perivasculitis.

Toxicology Results: Levamisole (2.8mcg /ml) present in the blood; no evidence of cocaine or cocaine metabolite was noted.

Discussion: Vasculitis is a known complication of levamisole use and has been reported to affect the skin, kidneys, and muscles of the lower extremities. Agranulocytosis, neutropenia, and arthralgia are also noted. The only case of death noted in the literature is a case of acute coronary syndrome following the use of levamisole-laced cocaine. In that case, the left anterior descending coronary artery was affected by the arteritis. In the present case, the intramural heart vessels were involved while the coronary arteries were unaffected. The lungs showed vasculitis of the medium-size vessels with predominantly an eosinophilic perivascular infiltrate accompanied by acute and organizing alveolar injury.

Vasculitis, Sudden Death, Levamisole

H13 Natural Death Caused by Catecholamine Toxicity Due to Pheochromocytoma in a Young Adult

*David K. Arboe II, MD**, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; *Kenneth H. Clark, MD, PhD*, Allegheny County ME, 1520 Penn Avenue, Pittsburgh, PA 15222; and *Todd M. Luckasevic, DO*, Allegheny County ME, 1520 Penn Avenue, Pittsburgh, PA 15222

After attending this presentation, attendees will understand the gross and microscopic characteristics of pheochromocytoma as well as laboratory findings associated with catecholamine toxicity.

This presentation will impact the forensic science community by enumerating the findings of pheochromocytoma and catecholamine toxicity and validating the necessity of complete autopsy examinations with histological analysis and ancillary laboratory testing.

A 22-year-old female with a questionable history of drug abuse complained of general malaise as well as a headache. She went to sleep in an attempt to alleviate her symptoms. She was found unresponsive on the floor next to the bed and was not able to be resuscitated. Her medical history is significant for a recently detected adrenal mass, recurrent hypertensive episodes, and elevated plasma and urinary catecholamines and their metabolites. Her family medical history is significant for von Recklinghausen disease (neurofibromatosis type 1).

At autopsy, multiple small cutaneous neurofibromas and café-au-lait spots were observed, supportive of a history of von Recklinghausen disease. The heart exhibited cardiomegaly and concentric left ventricular hypertrophy. Gross inspection of the right adrenal gland demonstrated a 5.5x5.0x3.5cm soft, brown, well-circumscribed mass arising from the medulla. Cut section of the lesion revealed soft, pink-brown tissue with multiple areas of hemorrhage. Microscopic examination of the mass showed large cells (some markedly pleomorphic) with basophilic cytoplasm, round nuclei, and prominent nucleoli in a nested arrangement with a rich intervening vascular network. A special laboratory chemistry request was made from a reference laboratory for measurement of free serum catecholamines. Chemistry of the plasma showed markedly elevated fractionated and free catecholamines (four orders of magnitude higher than the upper limit of normal). The cause of death was determined to be the result of catecholamine toxicity due to a pheochromocytoma of the right adrenal gland.

Pheochromocytoma is a rare neuroendocrine tumor that is seen in about 0.1% to 0.6% of people with hypertension. Estimates show an annual incidence of pheochromocytoma of approximately 1/100,000 people. Of those tumors, only 10% are found to be secretory. Pheochromocytomas generally follow the “10% rule” where approximately 10% of tumors are bilateral, extra-adrenal, show metastasis, and are seen in the pediatric population, respectively. Hereditary pheochromocytomas are seen in syndromes such as multiple endocrine neoplasia, Sturge-Weber, von Hippel Lindau, and von Recklinghausen disease. Familial tumors are more likely to be bilateral, multicentric, and are seen at a younger age.

Grossly, pheochromocytomas range from small to large with the mean of 7cm and 200g. They can be yellow, brown, or red and cut section may show a lobulated appearance, hemorrhage, or necrosis. Microscopically, pheochromocytomas are large cells with abundant basophilic or amphophilic granular cytoplasm with intracytoplasmic hyaline globules. The nuclei are round or oval with prominent nucleoli. There are rare-to-no mitotic figures. The cells can be arranged in a Zellballen, trabecular, or solid form and have a rich vascular network. Metastases are the best criteria for determining malignancy. Other criteria include mitotic figures, abnormal mitotic figures, spindling of tumor cells, necrosis, large nests of cells, high cellularity, and periadrenal adipose tissue invasion. Capsular and vascular invasion can be seen with benign or malignant lesions. Synaptophysin and chromogranin, immunohistochemistry stains are positive in tumor cells. S-100 can be used to stain the sustentacular cells. Hyaline globules within the cell stain positive with periodic acid-Schiff and resist degradation with diastase.

This case illustrates the broad range of diagnoses forensic pathologists must consider in their practice. Vigilance is required to ensure that proper collection techniques are performed for ancillary testing. For this case, a purple top tube of blood was required for the measurement of serum catecholamines, which is not a part of the autopsy standard operating procedure.

Pheochromocytoma, Catecholamine Toxicity, Adrenal Gland

Pathology/Biology Section - 2015

H14 Multiple Thromboses in a Case of Neonatal Dehydration and Failure to Thrive

Kristine D. Song, BA, University of Kentucky, Dept of Pathology, 315 Broadleaf Lane, Lexington, KY 40503; Beth E. Frost, DO, 126 Wabash Drive, Lexington, KY 40503; Meggen A. Walsh, DO, University of Kentucky, 800 Rose Street, Lexington, KY 40511; Sarah A. Higdon, MD, University of Kentucky, 800 Rose Street, Lexington, KY 40511; Cristin M. Rolf, MD, State of Alaska, MEO, 5455 Dr MLK Jr Avenue, Anchorage, AK 99507; and Gregory J. Davis, MD, UK Medical Center, MS 117, 800 Rose Street, Lexington, KY 40536-0298*

After attending this presentation, attendees will be more familiar with the antemortem signs and postmortem findings that may mimic neglect or head trauma in breast-fed infants with hypernatremic dehydration and failure to thrive.

This presentation will impact the forensic science community by explaining the ways in which intracranial hemorrhage and the physical signs of possible dehydration may be mistaken by the prosecuting pathologist for blunt force trauma or child abuse and neglect. Early recognition and monitoring of this condition by medical professionals may prevent the occurrence of avoidable complications of hypernatremic dehydration, including death.

The following is a case of multiple thromboses in an infant with failure to thrive and dehydration. This case demonstrates findings of vascular thromboses in end organs mimicking trauma in an infant.

A 13-day-old White male was found at 2:45 a.m. crying alone in a bassinet and was experiencing difficulty breathing. No pillows or blankets were reported in the bassinet with the infant. After feeding, the mother noted skin color changes and took the infant to the hospital at 4:15 a.m. The emergency department records reported shortness of breath and cyanosis of the hands and feet, lethargy, dehydration, and a two-pound weight loss since birth. The infant was intubated, but normal oxygen saturation was not achieved. He was subsequently transported to a different hospital where he sustained cardiopulmonary arrest at 5:25 a.m. Advanced cardiac life support efforts were initiated and intraosseous access was obtained, followed by normal saline infusion. Resuscitation efforts continued for 45 minutes and the child was pronounced dead at 6:00 a.m. Notification of death was received by the coroner, who sent the body to the medical examiner's office for autopsy.

At autopsy, the infant was markedly thin and demonstrated "tenting" on traction of the skin. Body weight at autopsy was 5lbs, 4oz compared to 7lbs, 15oz at birth. The oral mucosa was dry and the periorbital fat was diminished, giving the eyes a sunken and prominent appearance. Internal examination revealed minimal subcutaneous and visceral fat. Extravasated blood was in the right nephric space. Dissection of the viscera revealed multiple thromboses involving the pulmonary arteries with a wedge infarct of the left lung, the right renal vein with deep congestion of the kidney, and dural sinus thrombosis with hemorrhagic leukomalacia. No trauma was identified on or within the body. Hemorrhage of the brain was non-traumatic, ruling out physical injury to the head. Vitreous humor was inadequate for electrolyte analysis. Postmortem toxicologic examination was negative for drugs and ethanol; postmortem blood cultures were non-contributory.

Findings in this case such as brain hemorrhage and skin tenting suggestive of dehydration may be mistaken for blunt force injury or child abuse/neglect; however, this pattern of severe dehydration, weight loss, apnea, and death cannot simply be attributed to neglect or failure to thrive. Breast-feeding associated hypernatremic dehydration has been described in at least 178 infants in the literature since 1979.¹ Interestingly, like the infant in this case, all of these infants were reportedly born at term without complication or abnormalities.² Complications of this condition may include acute renal failure, elevated liver enzymes, disseminated intravascular coagulation, cerebral edema, intracranial hemorrhage, cavernous sinus thrombosis, and bilateral iliac artery thrombosis.^{1,2}

Inadequate volume of vitreous humor precluded the evaluation of sodium and urea nitrogen concentration; however, the findings in this case show such a striking resemblance to specific reports of hypernatremic dehydration and associated complications of weight loss, cerebral edema, transverse sinus thrombosis, and death in infants around the second week of life that it is the most likely cause of death.^{3,4}

The incidence of neonatal hypernatremia in breast-fed infants has been reported to be as high as 4%; therefore, the need for recognition and monitoring by health professionals is paramount.¹ Early detection and monitoring for hypernatremia may prevent an occurrence of this rare complication; awareness by medical examiners may prevent erroneous assumptions of abuse or neglect.

H15 Sudden Childhood Death Due to Acute Bronchospasm

Sarah A. Higdon, MD*, University of Kentucky, 800 Rose Street, Lexington, KY 40511; Beth E. Frost, DO, 126 Wabash Drive, Lexington, KY 40503; Kristine D. Song, BA, University of Kentucky, Dept of Pathology, 315 Broadleaf Lane, Lexington, KY 40503; Meredith H. Frame, MD, Office of the Associate Chief Medical Examiner, 100 Sower Boulevard, Ste 202, Frankfort, KY 40601; William O'Connor, MD, University of Kentucky Medical Center, Dept of Pathology & Laboratory Medicine, Lexington, KY 40536; and Gregory J. Davis, MD, UK Medical Center, MS 117, 800 Rose Street, Lexington, KY 40536-0298

The goal of this presentation is to present a case which serves as a rebuttal to the general misconception that bronchial asthma is seldom, if ever, a fatal disease.

This presentation will impact the forensic science community in terms of competence (ability) to include acute bronchial spasm secondary to asthma in the differential diagnosis for sudden natural death in a child who does not have a documented history of this disease. This case is an unusual presentation (sudden unexpected death) of asthma in a child with previously mild respiratory symptoms.

A 7-year-old African American female was sitting on the steps of the shallow end at a community pool when she was witnessed to clutch her chest and fall forward into the water. A lifeguard reportedly pulled her from the water after less than 30 seconds, at which time she was noted to have a pulse and was gasping for air. Cardiopulmonary Resuscitation (CPR) was initiated and the child was observed to vomit a small volume of water following the initial rescue breath. At this point, her pulse had noticeably weakened. Witnesses then described "seizure like" activity for 15-20 seconds after which she became pulseless and cyanotic. CPR was continued by emergency medical services upon arrival. The child was pronounced dead upon arrival at the local hospital. The coroner was contacted and the body was sent to the medical examiner's office for autopsy.

Review of medical records revealed a medical history negative for obstructive airway disease and positive for seasonal allergies only. Gross examination of the body revealed moderately congested lung parenchyma with no other pathologic abnormalities in any other organ system, including the heart. Microscopic findings of the lung showed an exuberant peribronchial/bronchiolar inflammatory infiltrate with a predominance of eosinophils, basement membrane thickening, mucous gland hyperplasia, and smooth muscle hypertrophy. Sections of lung also showed mucous plugging with abundant eosinophils. Given the intensity of bronchial/bronchiolar constrictive findings and eosinophilic infiltrate, the findings and cause of death are consistent with acute bronchospasm due to undiagnosed asthma. Multiple sections of myocardium, including the cardiac conduction system, were also examined and found to be unremarkable.

This death was unexpected due to the relatively mild or asymptomatic nature of her prior clinical picture. Prior to death, the subject did not carry the diagnosis of asthma and it is likely that her asthma was mistaken for seasonal allergy symptoms. This case represents an unusual presentation of asthma and its disease course. Within minutes of being presumably free of symptoms, the subject experienced cardiopulmonary arrest.

Asthma-related deaths usually result from a combination of physiological abnormalities involving respiratory failure with hypoxia, hypercapnia, and acidosis, right ventricular failure secondary to pulmonary hypertension, and/or pulmonary infection.¹ The mechanism for a hyperacute attack includes both bronchospasm and inflammation.² Histopathological findings in fatal asthma have been shown to range from global mucus filling of all airways to moderate involvement to virtually empty airways.¹ Postmortem examinations have revealed mucous plugging in up to 74% of cases.² Asthma mortality rates are particularly high among women, African Americans, and children aged 5-14 years.² This case serves as a rebuttal of the general misconception that bronchial asthma is seldom, if ever, a fatal disease.¹ Individuals suffering from a fulminant form of bronchial asthma are at potential risk for rapid progression from a relatively controlled state to death within minutes.¹ Even patients who are asymptomatic on a daily bases can have a fatal attack.² The possibility of idiosyncratic anaphylactic reaction cannot be ruled out, as patients with bronchial asthma may be more susceptible to anaphylaxis than the general population.¹

Bronchospasm, Sudden Death, Child

H16 Rapid Unexpected Death in Late Pregnancy Due to Ruptured Iliac Artery Dissection

*Julia Choi**, 22 S Greene Street, Baltimore, MD 21201; *Stephanie M. Richards*, University of Maryland School of Medicine, 655 W Baltimore Street, Baltimore, MD 21201; *Christine Yoo*, University Maryland Medical Ctr, Dept of Pathology, 22 S Greene Street, Baltimore, MD 21201; and *Allen Burke, MD*, University of Maryland School of Medicine, 22 S Greene Street, NBW51, Baltimore, MD 21201

The goal of this presentation is to introduce a case report and associated literature review which will provide the attendees with a better understanding of the incidence of arterial dissections during pregnancy and the postpartum period as well as the potential hemodynamic and hormonal causes of such dissections.

This presentation will impact the forensic science community by providing attendees with increased competence in identifying arterial dissections that may cause morbidity and mortality in pregnancy and the postpartum period. This presentation will also caution attendees to look for arterial dissections in cases of unexpected death in pregnancy and the postpartum period.

Arterial dissections associated with pregnancy and the postpartum period have been reported since before the Civil War. The most common sites are the aorta and the cerebral and splenic arteries. The etiology is unclear but likely due to a combination of hemodynamic and hormonal changes. A case of sudden death due to a ruptured iliac dissection in late pregnancy is presented.

A 32-year-old woman in the third trimester of pregnancy presented to the emergency department in hemorrhagic shock. A computerized tomography scan showed a retroperitoneal hemorrhage. While in the operating room, a linear transmural disruption was identified at the right iliac artery bifurcation. The patient expired during the procedure before vascular repair could be performed. An autopsy was performed and confirmed a right iliac artery dissection. Histological sections of the artery showed medial degenerative changes.

The causes and risk factors of pregnancy-associated arterial dissection are unclear. Traditional risk factors for arterial dissection include hypertension, atherosclerosis, pre-existing aneurysm, extreme physical exertion, and trauma. Systemic diseases can also predispose patients to arterial dissections. None of these risk factors were present in this patient. Rather, the majority of women with pregnancy-associated dissections were otherwise healthy, without a history of trauma, and with normal peripartum blood pressures.^{1,2}

It has previously been suggested that the physical pressure and hemodynamic stresses from the gravid uterus may contribute to dissections related to pregnancy.¹ This may be a contributing factor in iliac dissections; however, the majority of dissections occur above the diaphragm (aorta and cerebral arteries) and cannot be fully explained by this hypothesis.

Most dissections occur in the third trimester or the postpartum period and not during labor, suggesting that the stress and exertion associated with labor is not the cause of arterial dissections. In one study, there was no correlation between dissection and the length of the second stage of labor.² One case of aortic dissection occurred in a patient who underwent an elective cesarean section with no active laboring.³ These support the idea that the stresses of labor are not the cause of arterial dissections.

The most promising hypothesis involves hormonal changes that may contribute to alterations in the arterial walls, which increase the risk for aneurysms and dissection. The histologic changes described in dissecting arteries in pregnancy include fragmented reticulin fibers, alterations in the amount of acid mucopolysaccharides, loss of normal corrugation of elastic fibers, and smooth muscle hypertrophy.^{3,4} Comparable changes have been observed in pregnant women without clinical dissection, suggesting that these arterial alterations are due to hormonal changes in pregnancy.⁵

The mechanism for pregnancy-associated arterial dissections is unknown; however, this is a serious problem that can lead to significant morbidity and mortality if not properly diagnosed. Further research needs to be undertaken to determine other potential risk factors and to aid in early detection of such dissections.

Arterial Dissection, Pregnancy, Iliac Artery

Pathology/Biology Section - 2015

H17 Nutritional Child Abuse: A Case Report of Kwashiorkor and Vitamin D-Related Rickets

Michael S. Pollanen, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Charis Kepron, MD, Eastern Ontario Regional Forensic Pathology Unit, Eastern Ontario Regional Laboratory Association, 501 Smyth Road, Ottawa, ON K1H 8L6, CANADA; and Rebekah Jacques, Forensic Services and Coroner's Complex, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA*

After attending this presentation, attendees will use this case report to serve as a control in the assessment of rickets-related bone changes and fractures.

This presentation will impact the forensic science community by facilitating discussion about osseous injuries in malnourished children.

Osseous injuries are often found in cases of child abuse and can occur actively through trauma and/or in a passive way through neglect by means of malnutrition. The presence of bone fractures presents challenges for the forensic pathologist as consideration of a plausible counterexample(s) must be pursued to explain pathological findings at autopsy. A counterexample to pediatric bone fractures due to non-accidental trauma is "fragile bones" due to rickets, osteogenesis imperfecta, osteopetrosis, etc. This consideration was applied to a 28-month-old girl known to be below the 3rd percentile for weight who was fed a vegetarian diet limited to plants, breast milk, and dairy milk. Following a one-week history of low-grade fever, cough, and increased drowsiness, the toddler died in the mother's arm. Autopsy revealed: (1) classical rickets-related bone changes including a well-healed pathologic fracture of a rib, an increased thickness of the calvarium, delayed fontanelle closure, prominent nodular costochondral junctions of the ribs (rachitic rosary), chondral hypertrophy at metaphyses, genu varum, and parathyroid hyperplasia; and, (2) body weight and height below the 3rd percentile and non-specific changes in keeping with protein malnutrition including generalized edema, ascites, bilateral pleural effusions, and hepatic steatosis. Radiological and histological investigations of the skull, vertebra, sternum, ribs, and long and metatarsal bones supported the autopsy findings of rickets. Biochemistry investigations revealed an undetectable vitamin D, megaloblastic anemia, and hypoproteinemia. There was no evidence of competing causes (hepatobiliary, intestinal, pancreatic, renal disease, diabetes mellitus, or inborn errors of metabolism) to explain the autopsy findings. Other findings included chronic asthmatic bronchitis, chronic atopic dermatitis, and evidence of acute shock in the colon and brain. The cause of death was attributed to a combination of asthma and malnutrition.

A careful evaluation of the clinical history, scene, autopsy, and ancillary postmortem investigations (radiology and biochemistry) are necessary to diagnose severe vitamin D-related rickets and protein malnutrition. Following review of this presentation, attendees will gain an understanding of the histological and radiological changes in a toddler with severe vitamin D-deficiency rickets in the setting of protein malnutrition. Given the rarity of these constellations of findings, this single case may serve as a control in the assessment of rickets-related bone changes and fractures.

Vitamin D-Related Rickets, Kwashiorkor, Osseous Injuries

H18 Genetic and Histopathological Factors in Thrombo-Embolic Disease: Results of a Preliminary Experimental Study

Isabella Aquila, MD, Viale Europa, località Germaneto, Policlinico Universitario, S Venuta-Medicina Legale, Catanzaro 88100, ITALY; Fiorella Caputo, MD, Chair of Legal Medicine, Viale Europa Loc. Germaneto 88100 cz, Catanzaro, ITALY; Natalia Malara, PhD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Vannio Vercillo, MD, Asp Cs, Cosenza, ITALY; Silvia Boca, Viale Europa, Catanzaro, ITALY; Ciro Di Nunzio, MFS, PhD, Magna Graecia University, Viale Europa, Germaneto, Legal Medicine, Catanzaro 88100, ITALY; Enzo M. Di Fabrizio, PhD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand how a comprehensive approach to fatal thrombo-embolism that includes the analysis of the clinical history of the patients, the research for genetic factors, and the histological age determination of thromboemboli may result in a better definition of the disease.

This presentation will impact the forensic science community by demonstrating the importance of the prophylactic measures in Venous Thrombo-Embolism (VTE).

VTE is the third most common cardiovascular disease after myocardial infarction and stroke. The mortality rate is high and there are many deficiencies in the diagnosis, prophylaxis, and therapy. In this study, a retrospective analysis of the reports of 500 autopsies performed at the Institute of Forensic Medicine of Catanzaro between 2005 and 2014 was performed. Twenty-two cases in which pulmonary embolism was recorded as the cause of death were identified, consisting of 13 males (59%) and nine females (41%) with a median age of 56 years (range 14-93 years). All subjects were Caucasian except one Negroid subject. The clinical histories of the patients who died were analyzed, with the identification of the risk factors for VTE. In the case of hospitalized patients, the measures of prophylaxis and therapy were evaluated. The role of genetic risk factors in the disease, particularly Factor V Leiden (G1691A) mutation, which is the most common genetic factor of thrombophilia, was studied. The presence of the mutation was researched in DNA extracted from blood samples. Additionally, in order to obtain a histological age of the process, the histopathological features of thrombo-emboli were studied using histological sections stained by Hematoxylin-Eosin (H&E) and trichromic stains (Masson).

The results of the clinical and epidemiological data showed that 18 subjects (81.8%) had at least one risk factor for VTE, while in four patients (18.2%) no clinical data that could be related to an increased thromboembolic risk was identified. Seven subjects (31.8%) were more than 65 years old at the time of the event, seven (31.8%) had major trauma, and seven (31.8%) were surgical patients. An immobility period was recorded in five subjects (22.7%), four subjects (18.1%) were obese, and two (9%) were receiving antipsychotic drugs. Central catheterization was present in two subjects (9%) and pregnancy and postpartum status were present in an additional two patients (9%). Finally, one subject (4.5%) was suffering from chronic respiratory failure and one subject (4.5%) had limb paresis.

The retrospective analysis also revealed that 13 deaths (59%) occurred in a hospital setting while nine subjects (41%) died before having the opportunity to receive medical care. Among hospitalized patients, ten subjects (77%) were hospitalized for other diseases and suffered an episode of fatal thrombo-embolism during the hospital stay. Three patients (23%) arrived at the hospital presenting with symptoms of VTE and none received a correct diagnosis. Among hospitalized patients, eight subjects received prophylaxis with low molecular weight heparin, while two subjects, despite the risk, received no prophylactic treatment for VTE. In 12 out of 22 subjects (54.6%), it was not possible to find the thrombotic site. In the other cases, five (50%) were femoral thromboses, two (20%) inferior-caval, two (20%) iliac, and one (10%) saphenous. The genetic results showed that none of the patients carried a Factor V Leiden (G1691A) gene variant, not even the younger subjects or those who did not show any clinical data that could expose them to an increased risk. The histopathological analysis revealed the age of the thrombi. The study of the morphological features of the thrombo-embolic samples reported that eight samples (36.3%) were between one and three days of age, eight samples (36.3%) were between three and five days of age, and six samples (27.3%) were between four and 20 days of age.

The results of this study highlight the importance of early identification of risk factors and the setting of primary prophylaxis measures in order to prevent the onset of the thrombotic process, especially as the clinical diagnosis of VTE is notoriously inaccurate. Moreover, it is known that even the non-fatal cases of VTE can result in serious chronic complications such as post-thrombotic syndrome and chronic pulmonary hypertension. It is clear that an accurate prophylactic treatment would be useful not only to prevent death but also morbidity. The results of this study indicate that even if the prophylaxis is correctly performed according to the guidelines, death cannot be completely avoided. This observation poses a question concerning the validity of current treatment approaches, despite the ongoing research in the field of thrombo-prophylaxis.

Pathology/Biology Section - 2015

The genetic factors were determined to be non-significant in determining the risk compared to the environmental risk factors. The results of histopathological investigations showed that it can be a very large temporal range in which death can be avoided; therefore, early identification is important in order to prevent the progression of the disease to the fatal episode. In the histological age determination of thromboembolism, immunohistochemical investigations were not essential in establishing the cellularity of thromboembolic formation and are very expensive compared to basic histological investigations. The difficulty in finding the embolic source may be an important limitation in the age determination of the thrombotic process as it prevents evaluation of the residual thrombus. In this context, a decisive role could be played by postmortem computed tomography angiography. This imaging diagnostic method may be very helpful in the visualization of thrombus and may facilitate its subsequent detection during the autopsy.

In conclusion, there is a great need to implement diagnostic and prophylactic measures in VTE. It is necessary to pay more attention to the pathology and the risk factors, similar to what occurs with other cardiovascular diseases such as myocardial infarction. An accurate analysis of the clinical history of the subjects can be very useful to clarify the etiology of the disease while genetic investigation is not necessary. The histological age determination is essential to answer a number of questions about the nature and the evolution of the VTE, making it possible to establish the casual relationship between the exposure to certain risk factors and the occurrence of thrombosis.

Fatal Thrombo-Embolic, Histopathological Factors, Genetic Investigations

H19 Sudden, Unexpected Death Due to Fatal Rupture of an Undiagnosed Aneurysm of the Splenic Artery: A Forensic Approach

Luigi Papi, University of Pisa, Institute of Legal Medicine, Via Roma 67, Pisa 56100, ITALY; Stefania Fornaro, MD, Via Roma 55, Pisa 56100, ITALY; Laura Roas, MD, via Roma 55, Pisa 56100, ITALY; Federica Gori, MD, University of Pisa, via Roma, Pisa 56100, ITALY; David Forni, MD, University of Pisa, via Roma, 55, Pisa 56100, ITALY; and Ranieri Domenici, MD, University of Pisa, via Roma, Pisa 56100, ITALY*

After attending this presentation, attendees will be informed about a case of unexpected sudden death due to undiagnosed aneurysm of the splenic artery.

This presentation will impact the forensic science community by stressing the importance of performing accurate clinical and necropsy examinations for all cases of ambiguous sudden death.

Aneurysms of the visceral arteries are neither a rare feature nor undescribed in the forensic literature. Nevertheless, this case of an undiagnosed aneurysm of the splenic artery is reported because of its peculiar findings and the resulting medicolegal implications. The splenic artery is the most common site of a visceral artery aneurysm. Various statements about the frequency of visceral and splenic artery aneurysms are available in medical literature. The overall frequency of visceral artery aneurysms described in the literature ranges from 0.1% to 2%, with most of the visceral artery aneurysms involving the splenic artery. The data is mainly gained from postmortem examinations. Aneurysms of the visceral arteries are diagnosed in increasing number due to the use of imaging diagnostics. These incidental findings are mostly asymptomatic. The clinical relevance of visceral artery aneurysms is extremely variable and to some extent is dependent on the location and size. Non-specific gastrointestinal disorders and recurrent pain are possible manifestations. For large aneurysms, a pulsating mass may be palpable. Visceral artery aneurysms can rupture into various organs and the abdominal cavity, resulting in recurrent gastrointestinal bleeding, hemobilia, and a surgical abdomen. Extensive hemorrhage and hypovolemic shock may arise. Aneurysms occur congenitally or may be acquired as a result of arteriosclerosis, fibromuscular dysplasia, inflammation, and trauma. Among surgeons, there has not yet been a unanimous view on the preferential operative approach. In those patients with an aneurysm characterized by a diameter larger than 2-4cm, surgical interventions should be employed because of the increasing risk of rupturing.

A 38-year-old woman suddenly died at her home, in Portoferraio (Elba's Island, Italy) of unknown clinical causes. The day before her death, she woke up with nausea and vomiting. She went to the General Practitioner (GP) reporting symptoms such as diarrhea, abdominal colic, and vomiting. The GP, after a physical examination of the abdomen, performed an intramuscular injection of an antispasmodic and prescribed a gastroprotective and antiemetic therapy. After a partial regression of symptoms, the woman felt a severe abdominal pain and went to the nearest emergency room for treatment. At the hospital, a myocardial infarction was ruled out after an **electrocardiogram** and blood sampling for troponin and CK-MB were performed. No positive results were found. While hospitalized, the woman underwent radiological tests of the abdomen and was then discharged.

She returned home and had a light dinner before retiring. In the morning, after screaming due to acute pain, she suddenly died. Physicians who were promptly called could only confirm occurrence of the death. It was evident that the woman did not use any drugs and did not suffer from any disease, with the exception of a backache and heartburn over the previous two days.

The autopsy was performed at Portoferraio's hospital. The external examination did not highlight any relevant findings other than evidence of resuscitation efforts by the medical staff. Internally, approximately 1,000ml of blood was found in the intraperitoneal cavity. Additionally, the internal examination revealed a voluminous retroperitoneal blood clot in the perisplenic region as well as signs of blood loss, including pallor of the organs. To complete the autopsy, the block formed by esophagus-stomach-duodenum-liver-pancreas, spleen, and aorta was formalin-fixed for a more accurate investigation. The subsequent dissection yielded a ruptured, sacculated aneurysm of the splenic artery measuring 14mm in diameter. The data obtained at the autopsy attributed the death to internal bleeding resulting from a rupture of the aneurysm of the splenic artery.

Conclusions: The present case is especially interesting because the unexpected death came after non-specific symptoms caused by hemorrhagic shock resulting from the rupture of a visceral artery aneurysm. This case demonstrates the relevance of a careful postmortem examination in order to define the cause of death and assess for any eventual medical malpractice due to failure of a timely and accurate diagnosis.

Pathology/Biology Section - 2015

H20 A Tremor in the Hand That Rocks the Cradle: Fatal Consequences of Postpartum Angiopathy

*Rebecca Irvine, MD**, Department of Forensic Medicine, 50 Parramatta Road, Glebe, NSW 2037, AUSTRALIA; and *Michael Rodriguez, MBBS*, 50 Parramatta Road, Glebe 2037, AUSTRALIA

After attending this presentation, attendees will better understand fatal outcomes of postpartum angiopathy, its variable presentation, differential diagnosis, and uncertainties of its incidence, pathogenesis, and treatment. Attendees will also be able to describe its importance as an often unrecognized cause of maternal death and the role of autopsy (especially neuropathological examination) in diagnosis.

This presentation will impact the forensic science community by fostering recognition and optimal examination of cases of postpartum angiopathy which is of benefit to family, clinicians, and public health.

Maternal mortality is of singular importance, usually scrutinized by public health authorities. Acute neurological symptoms occurring after a seemingly uncomplicated pregnancy and delivery are particularly alarming. A fatal intracerebral hemorrhage in an otherwise healthy postpartum woman is reported; the proximate cause of death was not recognized by clinicians and the case was almost not reported for definitive investigation.

A 26-year-old woman underwent uncomplicated term vaginal delivery and was discharged five days later. Two days later, she developed endometritis; following intravenous antibiotics, she was discharged after being prescribed oral antibiotics. On the 13th postpartum day, she complained of feeling “peculiar” and had two brief episodes of dysphasia. She later sustained a tonic-clonic seizure, recovered fully, and was transported to the hospital where a Computed Tomography (CT) scan of the head showed no acute changes. She was transferred to a tertiary center for monitoring and further investigation.

A chest X-ray, CT scan of the pelvis and abdomen, and abdominal/pelvic ultrasound were normal. A lumbar puncture was unsuccessful, but soon afterward she developed a severe headache. She vomited, became incoherent, and rapidly became comatose. A CT of the head showed a large hemorrhage within the left frontal lobe. Subsequent scans showed no structural cause of the hemorrhage. She deteriorated and met brain death criteria six days after initial neurological symptoms.

Autopsy revealed a healthy-appearing woman with features of medical intervention and critical illness. Degenerative endometrial changes consistent with her postpartum status were present. A probe-Patent Foramen Ovale (PFO) was noted. The brain showed a large hemorrhage apparently arising in the left striatum extending into the frontal white matter and rupturing into the ventricle (with acute hydrocephalus), with secondary features of edema (transcranial/tonsillar herniation, left-sided sinus thromboses, and pituitary infarction). There was no identifiable structural etiology. No choriocarcinoma or septic foci were identified. The vessels showed no vasculitis or other abnormalities.

Postpartum angiopathy (Call-Fleming syndrome) usually presents within two weeks following normal pregnancy and parturition. It presents with an abrupt (maximum intensity within minutes), severe global or occipital headache (described as a “thunderclap” or “the worst”) and/or focal, transient neurological signs. Definitive diagnosis consists of angiographic demonstration of multiple segmental narrowing of large- and medium-sized cerebral arteries. Vasospasm is transient and initial angiogram may be normal.

No incidence numbers are available, although fatal cases and small studies are widely reported. Multiple reports suggest under-recognition, “more common than appreciated,” with a spectrum of outcomes, including disability. It is usually a benign condition, often grouped with “benign angiopathies” (a heterogeneous group of reversible cerebral vasospastic conditions), although this would seem to neglect uniquely postpartum physiology with hormonally mediated susceptibility to vasospasm and labile hypertension. Admissions for pregnancy-related strokes have increased since the early 1900s.

Pathogenesis is unclear. Vasospasm as a mechanism is favored by the typically benign outcome. Overlap with eclampsia is hypothesized and the use of vasospastic drugs (ergonovine, sumatriptan, bromocriptine) has been implicated in some cases.

Pregnancy is associated with an increased risk of cerebral events (venous thrombosis, subarachnoid hemorrhage, intracerebral hemorrhage), coagulopathy, vasculitis, migraine, and mechanical complications due to epidural (spontaneous cerebrospinal fluid leak, meningitis), as well as eclampsia (25% developing postpartum). The differential diagnosis is large, but most (except for vasculitis) can be excluded by imaging and laboratory studies.

No definitive treatment is established. Favored strategies include calcium channel-blockers and steroids; others include immunosuppression, aspirin, MgSO₄, hypervolemic therapy, and endovascular procedures (calcium channel blockers, balloon angioplasty, stents).

Pathology/Biology Section - 2015

Autopsy was helpful in this case in suggesting the etiology of this death, educating physicians, and excluding other causes, particularly given the PFO and potential for septic emboli.

Postpartum Angiopathy, Maternal Mortality, Postpartum Stroke

H21 Death Caused by Kawasaki Disease in Infants: Illustration of Three Cases and Literature Review

Emiliano G. Maresi, University of Palermo, Via del Vespro 129, Palermo 90100, ITALY; Antonina Argo, Via Del Vespro 127, Palermo 90100, ITALY; Stefania Zerbo, MD, Via Del Vespro, 127, Palermo 90100, ITALY; Azzurra M. Rizzo, MD, University of Palermo, Via del Vespro 129, Palermo 90100, ITALY; Francesca Portelli, via Dei Nebrodi 64, Palermo 90146, ITALY; Elisabetta Orlando, University of Palermo, Via del Vespro 129, Palermo 90100, ITALY; Elvira Ventura Spagnolo, University of Palermo, Dept of Biotechnology and Legal Medicine, Via Del Vespro n. 129, Palermo 90127, ITALY; Paolo Procaccianti, Via Del Vespro, N. 127, Palermo, Sicily 90100, ITALY; Emanuele G. Grassettonio, MD, University of Palermo, Via del Vespro 129, Palermo 90100, ITALY; and Massimo Midiri, University of Palermo, Via del Vespro 129, Palermo 90100, ITALY*

The goals of this presentation are: (1) to help attendees understand the manner of presentation of Atypical Kawasaki Disease (AKD) causing unexpected death in infants; (2) to take into account the clinical history and pathological and radiological findings to support diagnostics of the cause of death; and, (3) to perform a literature review to improve knowledge of Kawasaki Disease (KD) with atypical presentation for the forensic pathology community.

This presentation will impact the forensic science community by serving as a key aspect of KD investigation as it can augment traditional means of diagnostics in a systematized format via interdisciplinary communication and collaboration. In relation to cardiac aneurysm causing death, the crucial role of postmortem Nuclear Magnetic Resonance (NMR) imaging will be discussed.

This study reports three cases of AKD causing unexpected death in infants. Clinical history as well as pathological and radiological findings are taken into account to support determination of the cause of death. A literature review was performed to convey knowledge of KD with atypical presentation to the forensic pathologist community.

KD is an acute systemic vasculitis of unknown cause. It affects children younger than ten years of age, mostly those under three years of age. KD before the age of three months is rare. Although no specific laboratory tests exist that can definitively identify KD, there are clinical and laboratory findings that guide diagnosis and treatment. The currently accepted clinical diagnostic criteria for KD include fever for at least five days with four of the following symptoms: polymorphous rash; conjunctivae injection; oral mucosal changes; cervical lymphadenitis; and/or, erythema, swelling, or desquamation of the hands and feet. Diagnostic criteria for KD in infants two years of age or younger may be missed in cases of AKD. Patients with only four of these principal signs/symptoms may be diagnosed as having KD if coronary aneurysm is recognized. Laboratory studies show leukocytosis, elevated erythrocyte sedimentation rate, positive C-reactive protein, and thrombocytosis. As cases of KD may be rarely found in forensic pathology observation and tend not to be an obvious cause of death, especially in atypical presentation, showing findings of several infant cases may positively impact knowledge of such pathology. Early diagnosis may avoid mortality or negative patient outcomes.

Case Illustration 1: A case of AKD with a lack of typical clinical signs and a rapidly fatal course in a two-month-old infant. One week before hospitalization, the infant demonstrated rhinitis, coughing without fever, and later conjunctival hyperemia and an allergic exanthem on the chest and arms. On admittance, laboratory tests highlighted leukocytosis, thrombocytosis, elevated sedimentation rate, and positive C-reactive protein. General conditions were poor for seven days until sudden death occurred. The autopsy confirmed that death was due to cardiac tamponade caused by a ruptured and inflamed aneurysm of the left anterior descending coronary artery.

Case Illustration 2: A three-month-old male baby, three days after the compulsory vaccination and antipyretic administration, gradually showed eyelid conjunctivae and lip erythema, a diffuse cutaneous exanthem, and pharyngo-tonsillitis. He exhibited episodes of staring which lasted for a few seconds. The patient was hospitalized in the pediatrics and neonatology division for suspected sepsis. Death occurred nine days after admission from sudden cardiac arrest that was unresponsive to any type of intensive care. Autopsy revealed that the cause of death was due to a ruptured, inflamed aneurysm in the anterior descending coronary artery, with subsequent cardiac tamponade. The anatomical-pathological and clinical outline suggested AKD.

Case Illustration 3: A seven-month-old male baby, apparently well nourished and without fever or exanthem, was unexpectedly found agonal in his bed by his parents. He died in an emergency room a few hours later in spite of aggressive resuscitation efforts. Postmortem imaging was performed during the autopsy, with evidence of an occlusive thrombus in a left coronary artery aneurysm. Laboratory findings were consistent with AKD. The crucial role of postmortem imaging is discussed here in order to improve diagnosis tools.

Pathology/Biology Section - 2015

Discussion: Aneurysms of the coronary vessels are rare in children and in isolated forms they are indicative of KD. In KD, aneurysms occur in 15%-30% of patients, usually after an acute phase of the disease. Resolution or regression of aneurysms is found in more than 50% of KD cases, whereas thrombosis or rupture rarely complicate the remaining cases. KD is lethal in 0.5%-2% of patients and death always takes place suddenly and unexpectedly. In the acute phase of disease, death is caused by complications of coronary endarteritis (thrombosis with myocardial infarction) and myocarditis (myocardial insufficiency and arrhythmias).

Kawasaki Disease, Death, Diagnoses

H22 Thoracic Injuries Due to Cardiopulmonary Resuscitation in an Infant: A Case Report

Michael S. Pollanen, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Kona Williams, MD*, Forensic Services and Coroner's Complex, 25 Morton Shulman Avenue, Toronto, ON M3M 1J8, CANADA

After attending this presentation, attendees will have an increased awareness of the potential pitfalls involving resuscitation artifacts in infants and how to differentiate these injuries from trauma inflicted prior to resuscitation.

This presentation will impact the forensic science community by presenting a case of Cardiopulmonary Resuscitation (CPR) injuries in an infant. These injuries, such as rib fractures and visceral trauma, are rare findings at postmortem examination. Nevertheless, it is critical that these injuries be recognized and differentiated from trauma caused by fatal child abuse prior to resuscitation attempts.

A case of a 4-month-old infant who died suddenly and underwent prolonged CPR is reported. He was born at full term via caesarean section with no prenatal or perinatal complications. There was no history of child protective services involvement or domestic violence. The child was found at night in his crib, unresponsive and in the supine position over blankets and a shawl. He had no vital signs upon arrival by the paramedics, who immediately administered full resuscitation measures. At autopsy, there were no external signs of recent trauma. There were minimally hemorrhagic left lateral rib fractures involving ribs 2-6, with extra-osseous displacement of bone marrow and crush artifact. There was extensive subpleural hemorrhage of the lungs with a resultant left hemothorax. No other injuries were found, no disease process was evident, and no congenital anomalies were identified. Toxicological, microbiological, and biochemical studies were non-contributory. A full neuropathological examination by a neuropathologist showed no significant findings. The cause of death was undetermined.

Based on a clinicopathologic correlation, the thoracic injuries were best attributed to the prolonged CPR, rather than injuries that occurred prior to death. These resuscitation artifacts are well-documented and are commonly seen at the adult autopsy in cases when CPR was administered. These artifacts have been thought to be an unusual finding in infancy; however, emerging data has shown that CPR-related rib fractures can occur in children.¹⁻³ This case underscores the emerging data that indicates rib fractures and other injuries can occur in collapsed infants who are subjected to CPR.

H24 Survival of Blow Fly Pupae After Submergence in Fresh, Salt, and Polluted Water

Paola A. Magni, PhD*, University of Western Australia, Centre for Forensic Science, Myers St Bldg, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA; Samanta Wolff, BSc, University of Turin, Dept Life Sciences and Systems Biology, via Accademia Albertina 13, Torino 10100, ITALY; Massimo Meregalli, PhD, University of Turin, Dept Life Sciences and Systems Biology, Torino, ITALY; and Ian Dadour, PhD, University of Western Australia, Centre for Forensic Science, 35 Stirling Highway, M420, Nedlands, Western Australia 6009, AUSTRALIA

After attending this presentation, attendees will understand that the pupal stage of a blow fly can add another capability to forensic entomology practice and add another dimension to determining the minimum Postmortem Interval (PMI) when insects are found on a floating corpse.

This presentation will impact the forensic science community by providing data that will be potentially useful in adding a new component to estimating the overall duration of the floating time of corpses in forensic investigations that can assist in determining the minimum time-since-death.

Blow flies (Diptera: *Calliphoridae*) are generally the first insects that colonize a corpse in the terrestrial environment. In an aquatic environment, a body proceeds through a series of sinking and floating phases (bloat) and it is during the float phase that calliphorids can colonize a body in the water. Calliphorids collected on a body found in an aquatic environment can help to determine how long the remains have been floating and this information can assist in determining the minimum time since death. At present, only incomplete experiments exist concerning the capacity of any calliphorid life-history stage to survive reduced oxygen tension and whether they can survive submersion in water. Many previous authors have alluded to the forensic utility of blow fly immatures when a body is submerged, but again it is all anecdotal evidence.

The goal of this research is to estimate the survival of *Calliphora vomitoria* L. pupae in sea water, fresh water, and polluted water. Polluted water was collected from the Po River in Turin, Italy. Waters used in this research were chemically analyzed (pH, hardness, salinity, Na, K, Ca, Mg, Cl, NO₂, NO₃, NH₄, PO₄, SO₄, NH₄, and HCO₃).

Pupae (N=30 for each treatment) were sampled at different stages of their development (24 hours, five days, and nine days following pupation) and placed underwater for a minimum time of one hour to a maximum time of ten days. Pupae were placed in an open-weave mesh bag and weighted down so they remained completely submerged. Pupae were then removed from the water and placed in a dry environment. The time required to eclosion and the survival rate was recorded and compared with non-submerged, control pupae (N=100). During the entire experiment, the environmental temperature was 23°C and the water temperature was 24°C.

Preliminary results to date demonstrate that the survival of pupae decreases with increasing time of submergence. In general, no pupae survived following five days of immersion. Lower survival also occurred among pupae submerged in seawater over equivalent time periods. The time required to eclosion for control pupae and pupae immersed for 24 hours is not statistically different.

This study provides data potentially useful in estimating the floating time of corpses in forensic investigations when pupae are found adhering to, or entangled in, the decaying flesh, hair, or clothes of a corpse that has become submerged after the larvae had developed and pupated. This research complements the study by Singh and Greenberg and adds vital details to the questions of floating time and, hence, the overall minimum PMI.¹

H25 Postmortem Artifacts Caused by the Water Beetle *Rhantus Validus*, Sharp (Coleoptera: Dytiscidae) on a Corpse Found in a Pond in Región de La Araucanía, Chile

Christopher Oses, BSc, Depto. Ciencias Básicas de la Facultad de Medicina, Universidad de La Frontera, Temuco, CHILE; Edoardo Tosti-Croce, PhD, Depto. Ciencias Básicas de la Facultad de Medicina, Universidad de La Frontera, Temuco, CHILE; Herbert Viveros, BSc, Brigada de Homicidios de Temuco, Policía de Investigaciones de Chile, Temuco, CHILE; and Paola A. Magni, PhD*, University of Western Australia, Centre for Forensic Science, Myers St Bldg, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA

After attending this presentation, attendees will understand the potential capabilities and limitations of forensic entomology practices in order to determine the nature of injuries found on a body when insects are found on a floating corpse.

This presentation will impact the forensic science community by providing information that will be potentially useful in adding a new component to determine the circumstance of death of a corpse found in an aquatic environment.

The estimation of the time since death, determination of the manner of death, identification of the individual, and the pathological evaluation of a body can be impeded by postmortem changes. More accurate diagnosis of these changes are a result of continued research in forensic entomology and case studies; however, at present there is scant literature concerning forensic entomology and decompositional processes in aquatic environments.

In the majority of cases a body placed in water progresses through a series of sinking and floating phases. During the float phases, necrophagous blow flies (Diptera: *Calliphoridae*) and flesh flies (Diptera: *Sarcophagidae*) can colonize a body in the water. Some other aquatic or semi-aquatic insects can use the submerged body as an eventual source of food or as a substrate to attach (e.g., Diptera: *Simuliidae*, *Chironomidae*), but in water there are no specialized carrion insects.

The case study presented involves a decomposed body found in an artificial pond in Región de La Araucanía, Chile, in April 2014. The body was in the early floating stage, six feet from the edge of the pond. The face and majority of the body were immersed in the water, while the ears, the posterior part of the head, and the shoulders were exposed to the surface. Adult water beetles *Rhantus validus* Sharp (Coleoptera: Dytiscidae) were found on the body, associated with injuries on the skin. Water beetles such as *R. validus* are semi-aquatic insects adapted to living in water both as larvae and adults. These species of water beetles carry an air bubble between their abdomens and elytra which provides an air supply and have hind legs adapted for swimming. They are predatory insects with short and sharp mandibles. When they bite, they immediately deliver digestive enzymes.

The water beetles were collected from the body at the crime scene and sent to an entomologist. No other species of arthropods associated the corpse were observed. Four water beetles were found behind the left ear of the body, crawling in an asymmetrical groove of approximately 30x10mm (length x width), while one water beetle was found crawling inside an oval hole (10mm diameter) with regular margins on the upper part of the chest. The entomologist was asked to help clarify the nature of these injuries, in particular, if they could be postmortem artifacts caused by the predatory activity of water beetles on the body.

Postmortem Artifacts, *Rhantus Validus*, Freshwater Environment

Pathology/Biology Section - 2015

H26 Biodiversity of Functional Genes: An Aid in Soil Provenance

Priyanka Kushwaha, MS*, Florida International University, 11200 SW 8th Street, Miami, FL 33174; Jacqueline Zayas, BS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Yanie Oliva, BS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Maria A. Mendoza, PhD, 11200 SW 8th Street, Biological Sciences, OE 167, Miami, FL 33199; Beatrice Kallifatidis, MS, 11200 SW 8th Street, Bldg. OE/Room 167, Miami, FL 33199; and DeEtta Mills, PhD, Florida International University, OE 167, Biological Sciences, 11200 SW 8th Street, Miami, FL 33199

The goal of this presentation is to acquaint attendees with the use of DNA microbial profiling for discrimination/comparisons of soil samples. Also, attendees will gain insight on the use of functional markers to define microbial communities and how their use will strengthen the crime scene investigations involving soil as evidence.

This presentation will impact the forensic science community by laying the foundation to adopt the use of functional markers over universal markers as they represent the true microbial community profile and would be better for studying soil structure.

Soils are treated as important pieces of evidence in forensic investigations owing to their mineral and organic properties. Most often, soils are examined utilizing physical properties such as color, particle size, and mineral content; however, these techniques do not always result in successful categorization of the samples. Hence, laying the path to complementary approaches such as that proposed by Horswell et al. DNA profiling of soil bacterial communities using terminal restriction fragment length polymorphism can be employed for forensic comparison and discrimination of soils. This method is advantageous as it does not require a large sample size and the equipment is already owned by the forensic laboratories for human DNA analysis, making it more cost-effective.

Studies have demonstrated that microbial soil community structure can be determined from small soil samples across different locations and can be used for comparisons. Based on the existing ecological literature, it is suggested that variations exist in microbial community profiles across land management and vegetation types. Thus, microbial community profiling can potentially be employed as an intelligence tool for the providence of unknown soil samples collected from crime scenes.

Soil bacterial community profiles have been categorized using 16S rRNA hypervariable domains. These domains are effective in constructing a DNA profile that would enable discrimination between various soil samples; however, 16S rRNA profile alone is not adequate to establish the functional diversity of these microbes. Microbes play an important role in maintaining the stability of soils by cycling the biochemical nutrients such as carbon, phosphorus, nitrogen, sulfur, and iron. These processes are carried out by the enzymes produced by soil microorganisms. Thus, investigation of these functional enzymes can provide a better understanding of the function of the soils.

The objective of this study was to compare the functional diversity of microbial communities among different soil types: Lauderhill Dania-Pahokee (soil type 2) and Perrine-Biscayne-Pennsuco (soil type 4) of Miami-Dade County, FL.

DNA was extracted from samples (n=36) collected from one transect belonging to each soil type. Degenerate primers for *mcrA*, *cel48*, and *dsrA* were used to amplify the gene using polymerase chain reaction followed by cloning and sequencing. Sequences were analyzed by Basic Local Alignment Search Tool (BLAST) and subsequently aligned to construct a phylogenetic tree.

Comparison of sequences of the *mcrA* gene obtained from KNT and CS transect with sequences from other Florida studies resulted in close alignment with *Methanothermobacter thermautotrophicus*; however, many were not associated with any known reference samples. The KNT- and CS-labeled sequences associated almost exclusively with either uncultured archaea or with the uncultured euryarchaeote from oligotrophic soils in the northern Everglades. While some of the clones from the two soil types examined in Miami-Dade County grouped together with a particular soil type, there was overlap in the clones from the different soil types. These overlaps for the gene *mcrA* are indicative of saturated anoxic soils which are also useful for discrimination of environmental ecosystems. Thus, the study of these overlaps is important as it can also provide useful information.

The assessment of phylogenetic and functional abilities of microbial communities will clarify the importance of microbes for soil function and hence define its structure. A well-characterized structure can thus be of extreme importance in soil provenance.

Functional Genes, Microbial Community Profiling, Soils

H27 The Application of Novel Next Generation Sequencing (NGS) Technology in Forensic DNA Research

*Chia-Hung Huang**, Institute of Forensic Medicine, No.123, Min'an Street, Zhonghe District, New Taipei City, New Taipei City, TAIWAN, ROC; *Tsun-Ying Huang*, No.123, Min-An Street, Zhonghe District, New Taipei City 235, TAIWAN, ROC; *Fang-Chun Chung*, MS, No 166-1, Sec. 2, Keelung Road, Taipei 106, TAIWAN, ROC; and *Chun-Yen Lin*, 123 Min-An Street, Zhonghe District, New Taipei City, TAIWAN, ROC

After attending this presentation, attendees will see the merits of Next Generation Sequencing (NGS) in forensic mitochondrial DNA typing and the advantages and disadvantages of different sequencing techniques.

This presentation will impact the forensic science community by shedding light on the discrepancy of mitochondrial DNA sequencing by Sanger's sequencing, ion-semiconductor sequencing, and sequencing-by-synthesis, which also paved the way for the application of NGS to forensic DNA typing.

In forensic medicine, mitochondrial DNA provides the evidence of maternal inheritance; the high variable regions (HV-1 and HV-2) in the D-loop are the most informative among all. The traditional Sanger's sequencing can generate high-quality mtDNA sequencing data; however, this can be a tedious task under the pressures of time limitation and human resources. In contrast, NGS offers more reads at the price of higher cost. Thus, this study compares the cons and pros of NGS with Sanger's sequencing.

Twenty-two anonymous cases were selected. Sample types included oral swabs for three cases, muscle for three cases, and bone for 16 cases. For Sanger's sequencing, HV-1 and HV-2 were amplified independently and the PCR products were purified and sequenced with 3130xL. For NGS, the DNA samples were amplified using two pairs of mtDNA-specific primers. The two amplicons covering the entire mitochondrial genome were ~8.5kb for each with some overlap and were subjected for library preparation. In brief, for ion-semiconductor sequencing, the amplicons were sheared to suitable size using a shearing enzyme, tagged with different barcodes to identify different cases, and amplified with emulsion Polymerase Chain Reaction (PCR) to provide adequate signal strength. A higher sequencing depth indicates a better data quality. Since the sequencing depth has coverage ranges of 1,500-folds, this indicated that the quality of the data was very high. For sequencing-by-synthesis, the amplicons were fragmented and tagged simultaneously by special transposase, labeled using different barcodes, and amplified with bridge-amplification in order to provide sufficient fluorescence signal. The sequencing depth maintained a coverage range of 2,000-folds, which shows that the data should be very accurate. Variants called from different platforms were compared, while 19 cases were determined by ion-semiconductor sequencing, 21 cases were determined by sequencing-by-synthesis, and all of their HV-1 and HV-2 regions were determined by Sanger's sequencing.

The polymorphisms of HV-1 and HV-2 regions include Single Nucleotide Polymorphism (SNP), indel, and heteroplasmy; most of the SNP could be identified by both NGS platforms. Moreover, both NGS platforms showed better sensitivity in detection of heteroplasmy and the determined heteroplasmic proportions were in concordance between the two platforms; however, in detecting indels, there were some discrepancies between them. For ion-semiconductor sequencing, the homopolymer emitted an accumulated proton signal, and thus the algorithm needed optimization, setting "hot spots" previously to approach the accurate length of homopolymer. For sequencing-by-synthesis, few adjustments were required for the estimated length of homopolymer. In some cases, the estimated lengths of sequencing-by-synthesis were one-base longer than the length determined by Sanger's sequencing. This is probably due to the conservative fashion of the determination of Sanger's sequencing.

The DNA quality should be a critical issue in the preparation of amplicons. In this report, the DNA samples from the bones were severely damaged. The DNA quantities extracted from the bones were poor and barely met the requirements of long-range PCR. NGS platforms brought resolutions for this challenge. For the whole mitochondrial genome, the company recommended different optimized primers for different platforms to amplify the genome, as well as shorter amplicons. Furthermore, both NGS techniques (ion semiconductor sequencing and sequencing-by-synthesis) suggest that transposase should be used in order to construct the library. This not only dramatically shortened the consumption of amplicons but also decreased the labor input. These improvements could make NGS more feasible in forensic DNA analysis.

H29 Genotyping of Used Drug Stamp Bags With Special Attention to the Minor Contributor

Aaron Beaver, BA, 1420 Centre Avenue, Apt 1317, 55 Van Braam, Pittsburgh, PA 15219; and Lisa R. Ludvico, PhD, Duquesne University, Biology Dept, 238 Mellon Hall, Pittsburgh, PA 15282*

After attending this presentation, attendees will better relate to the importance of evidence collecting, specifically DNA, of stamp bags found on-scene. Attendees will also learn of new and original changes to procedure to produce higher DNA yield.

This presentation will impact the forensic science community by showing that DNA can be obtained in sufficient quantities for a short tandem repeat profile from drug evidence at a crime scene and by providing several useful testing methods which vary in terms of time and expense.

Currently under review in the United States court system is the question of what penalty, for sentence and category of crime, should be applied to a distributor of illegal drugs in the event that those drugs were responsible for the death of a user. Touch DNA (tDNA) is the DNA that remains behind when an individual touches an object. It is very common for the tDNA to also be characterized as trace DNA, which is defined as being less than 100 picograms. It has been found that tDNA can be left behind on a number of items that a user might touch. A large quantity of drugs can normally be found wrapped up in magazines. Some research was done as to whether DNA could be obtained from these magazines; it has so far been determined to be improbable; however, since the drugs are distributed to users in smaller bags, known as “dime bags” or “stamp bags,” and these bags are normally made out of some waxy material, it was hypothesized that DNA could be obtained from these waxy, non-porous bags.

Research suggests that a detectable amount of DNA can in fact be obtained from drug stamp bags. The preliminary test, which had an average concentration of 1.47E-03 nanograms per milliliter, was conducted by using a double-swab method using PSS Select® Cotton Swabs on touched bags. The DNA was extracted via the Promega® DNA IQ™ System kit and analyzed on the rtPCR machine using the Life Technologies™ Quantifiler® Human DNA Quantification Kit provided by the laboratory. There was also a known DNA positive control along with a no DNA negative and a non-touched bag negative control. Genotyping was done with an ampFISTER® Identifiler® Plus PCR Amplification Kit on the 3130xl Genetic Analyzer.

It was hypothesized that a large amount of DNA was being lost due to the PSS Select® Cotton Swabs. In addition to the double-swab method, an enzyme was used to enhance the DNA yield. Also, sample bags were cut into pieces and a reworked PCI method was developed to more greatly enhance the DNA yield from the stamp bags.

This additional step provided samples that, when concentrated, produced viable DNA concentrations, some over the optimal 1ng for the ampFISTER® Identifiler® Plus PCR Amplification Kit protocol. Full profiles were found for several of the samples. This research is important because there are an increasing number of drug-related deaths and the person(s) making or delivering the product is left unpunished. If a full profile of the dealer or distributor can be determined, it is possible to target and reduce the places and sales of heroin and thus the amount of heroin overdoses per year.

DNA Yield, Drug, Stamp Bag

H30 Death Following Retrobulbar Injection of Desmopressin for the Treatment of Non-Arteritic Anterior Ischemic Optic Neuropathy: Which Implications Indicate This Off-Label Use?

Benedetta Guidi, MD, Via Santa Dorotea 1, Pescia, Pistoia 51017, ITALY; Valentina Bugelli, MD*, Institute of Legal Medicine, via Roma 55, Pisa 56126, ITALY; Stefania Fornaro, MD*, Via Roma 55, Pisa 56100, ITALY; Marco Di Paolo, via Roma 55, Pisa 56100, ITALY; and Marco T. Tuccori, MD, Via Roma 55, Pisa 56100, ITALY*

After attending this presentation, attendees will be aware of the possible clinical and legal implications following off-label use of corticosteroids and desmopressin for the treatment of Non-Arteritic Ischemic Optic Neuropathy (NAION).

This presentation will impact the forensic science community by illustrating a case of fatal acute myocardial infarction after retrobulbar injection of a synthetic replacement of vasopressin.

Since a standard treatment for NAION with proven efficacy is not available to date, most therapeutic approaches are empirical and include a wide range of agents presumed to act on thrombosis, on the blood vessels, on the disk edema, or presumed to have a neuroprotective effect. Among other proposed treatments, retrobulbar injection of corticosteroid and desmopressin represents an invasive approach, with potential for local and systemic complications, which does not appear to have been documented previously. The rationale of using desmopressin in the treatment of NAION is uncertain and perhaps a result of experimental findings demonstrating that desmopressin induces ciliary artery relaxation in dogs via V1-receptors through a mechanism which involves nitric oxide. In turn, this would enhance vascular permeability, thus facilitating the re-absorption of optic edema. A similar vasodilation effect can be attributed to corticosteroids.

A 60-year-old man, apparently healthy and with a negative history for cardiovascular disease, was hospitalized because of a unilateral sudden and painless severe visual loss (20/200) upon waking in the morning. The optic disc appeared hyperemic and edematous, with a focal severe swelling. Relative inferior altitudinal scotoma was present at visual field examination. The patient presented with an erythrocyte sedimentation rate 20mm/h and normal levels of plasma fibrinogen and C-reactive protein. The diagnosis of NAION was made. Two separate and immediately consecutive injections of betamethasone (2mg/0.5ml) and desmopressin (2mcg/0.5ml) were performed in the retrobulbar space. The administration of any preoperative medication or cardiovascular examination was not documented. In the patient's medical records, the total volume of the injections and the size of the needle used are not specified. The procedure was technically uncomplicated without any monitoring in progress during injections such as Electrocardiogram (ECG), peripheral oxygen saturation, or blood pressure measurement. Fifteen minutes later, the patient suddenly developed a cold sweat, dyspnea, thoracic pain, and severe hypotension. ST segment elevation acute myocardial infarction was diagnosed by ECG. Intensive care support was initiated; however, despite cardiopulmonary resuscitation, the patient died from irreversible cardio-respiratory arrest. At autopsy, the heart presented with a normal shape and weight (350g); coronary arteries showed significant atherosclerotic luminal narrowing. Histological investigation showed a stenotic atherosclerotic plaque (95%) complicated by culprit thrombosis of the left anterior descending artery, 2cm after its origin. Examination of the other organs was unremarkable, except for mild pulmonary edema and polyvisceral stasis. There was no evidence of increased orbital volume or sign of vagal compression secondary to retrobulbar hemorrhage.

Professional autonomy in the health care decision-making process renders the physician free to prescribe a drug for purposes other than that for which it has been approved, when the physician considers it both safe and effective according to his/her professional judgment.

The use of unlicensed and off-label medicines is a widely used medical practice, mainly in certain clinical settings. A physician's autonomy in healthcare decision-making represents an instrument to guarantee the progress and evolution of scientific knowledge while also practicing the most effective safeguards for health protection and promotion.

Though off-label prescription use is common and sometimes necessary for providing a pathway to clinical practice innovation, it presents significant risks. This practice may lack rigorous scientific scrutiny and there is little known about the degree of scientific evidence supporting it. According to the literature, a high percentage (approximately the 73% of off-label use) had little or no scientific confirmation. Unexpected adverse effects represent a possible risk. Since the off-label practice may expose patients to avoidable risks, it is mandatory for doctors to follow the lawful direction and ethical recommendation.

Pathology/Biology Section - 2015

This case is out of the ordinary for the forensic scientist because of the possible recognition of medical liability for personal injuries and murder when a patient experiences psychological and/or physical damage or dies as a consequence of the administration of an off label drug.

Desmopressin, NAION, Off-Label Prescription

Pathology/Biology Section - 2015

H31 Death Due to Butane and Propane Gas Inhalation in a Cell Block

Francesco Saverio Romolo, PhD, Sapienza Università Di Roma, Dipartimento SAIMLAL, Viale Regina Elena 336, Roma 00161, ITALY; Paola A. Fiore, Via Francesco Ferrara, 24, Rome 00191, ITALY; Simone Cappelletti, MD, viale Regina Elena 336, Rome, ITALY; Alessandro di Luca, MD, Viale Regina Elena, 336, Rome 00161, ITALY; and Costantino Ciallella, Viale Regina Elena 336, Rome, ITALY*

The goal of this presentation is to stress the importance of a correct methodology and multidisciplinary approach in cases where a chemical forensic expert is fundamental for case resolution.

This presentation will impact the forensic science community by illustrating the roles of the forensic toxicology and forensic pathology experts in cases of chemical intoxication by gases.

The case reported for this study occurred in a prison, where a cellmate found a 29-year-old convict unconscious on the bathroom floor of the cell. The cellmate, awoken by the strong smell of gas, rushed into the bathroom and found the man unconscious next to a gas camping stove that was still leaking gas. After resuscitation attempts, the man was declared dead and the body was moved to the morgue. Crime scene officers examined the prison cell. Two camping stoves were found, one in the bathroom and the other on the table of the cell. The deceased convict was a Latin American male, 185cm in height and 84.5kg in weight. External examination showed no evidence of injuries on the body; the presence of subepidermal petechial hemorrhages on the rear region of the chest was reported.

The autopsy revealed an intense passive congestion of the meningeal vessels. Nearly the entire surface of the right lung exhibited emphysematous bubbles, particularly in the inferior lobe. Examination of the heart identified a bilateral dilatation of ventricular cavities and focal myocardial fibrosis with pervious coronary vessels. Specimens of brain, lungs, heart, and coronary arteries were collected for histological analysis as well as specimens of liver, spleen, kidneys, and pancreas. Samples of heart blood, peripheral blood, gastric contents, urine, bile, and vitreous humor were collected during the autopsy and stored at -20°C for further toxicological examination. In addition, samples of brain, subepidermal fat tissue, liver, kidneys, heart and peripheral blood were collected in separate gas-tight containers. Air from the right and left bronchus and from the emphysematous bubbles of the right lung was collected using medical syringes. The gas-tight vials and the medical syringes were stored at -20°C for further toxicological examination. A routine microscopic histopathological study was performed. The lung sections showed marked congestion of alveolar septa and margination of the intralveolar contents with enlargement of alveolar spaces in the form of "blebs". The diffuse presence of subpleural bubbles, peripheral subpleural emphysema, and edema were observed. The heart sections showed stretched and wavy myocardial cells, consistent with dilatation of the ventricular chamber, as well as evidence of focal perivascular fibrosis. Intensive congestion of the liver and kidneys was observed. Toxicological analysis was performed on all specimens reported above. Screening tests performed with immunochemical technique both on urine and on blood detected the presence of benzodiazepines. No ethanol was detected in urine, peripheral, or heart blood. Propane and butane were identified and various concentrations of the two gases were measured by toxicological analysis in all specimens collected, as well as in the air collected from the bronchi and from the emphysematous bubbles of the right lung.

The analytical procedure based on gas chromatography/mass spectrometry analysis and the data obtained will be presented and thoroughly discussed both from the forensic pathology and the forensic toxicology point of view.

Butane and Propane Mixture, Camping Stove, Death in Custody

Pathology/Biology Section - 2015

H32 Effects of Different Killing and Storage Methods on Larval Length of the Blow Fly *Lucilia Sericata*

Valentina Bugelli, MD*, Institute of Legal Medicine, via Roma 55, Pisa 56126, ITALY; and Jens Amendt, PhD, Institute of Forensic Medicine, Dept of Biology, Kennedyallee 104, 60596 Frankfurt am Main, Frankfurt, GERMANY

The goals of this presentation are to provide attendees with information concerning a survey about the current state-of-the-art in sampling insects from a body and the crime scene and to illustrate a fast and easy way of sampling, killing, and storing entomological evidence.

This presentation will impact the forensic science community by explaining different killing and storage methods and their implications on minimum Postmortem Interval (PMI_{min}) estimation.

Forensic Entomology (FE) is an important tool to estimate the PMI_{min} by using the oldest insect life stage such as fly larvae collected at the crime scene and from the body itself during the autopsy. Sampling, killing, and storing methods are very important because they can influence survival and growth rate of living samples as well as influence the result of the morphometric examination of the dead specimens. There are several manuals on best practices in FE, leading to a certain amount of heterogeneity regarding the methods of sampling and storing insect evidence. Moreover, quite accurate recommendations exist which might confuse or even discourage the crime scene technician or pathologist and lead to unnecessary challenges at court when a report doesn't follow these recommendations. Interestingly, the scientific background for these recommendations and manuals is quite fragile as just a few studies examined so far note the effects of different killing and storage methods. The manuals should be: (1) as simple as possible; and, (2) based on scientific experiments which demonstrate the accuracy and validation of such recommendations. The present study deals with the killing and storage of the forensically relevant blow fly *Lucilia sericata*.

Three hundred newly hatched *L. sericata* larvae were supplied with ground beef *ad libitum* in an incubator at 20°C. For three days, 100 larvae were sampled from the food source every 24hrs and divided in two equal subsamples. The first subsample was killed by Hot (but not boiling) Water (HW) and stored in 75% ethanol. Half were stored at room temperature and the other half in a refrigerator at 6°C. The second subsample was killed by boiling in 75% ethanol and left in this killing solution (HE). Half of these were stored at room temperature and the other half in a refrigerator at 6°C. Lengths of all larvae were measured immediately after killing and every 24hrs until day four, then once more after seven days. This experiment was repeated two times with the same numbers. The data were captured in Excel® 2003 and analyzed with GraphPad® Prism® 5. The Kruskal Wallis Test showed no significant change in length of stored larvae, except for two treatments in the HW group which were stored under room temperature. While 24-hour-old larvae showed a significant decrease in length after four days of storage time (min 0.2cm, max 0.7cm, median 0.4cm vs. after day four min 0.15cm, max 0.68cm, median 0.33cm; p=0.0234), the 72-hour-old larvae revealed a slight significant increase in length after one week of storage (min 0.62cm, max 1.9cm, median 1.15cm vs. after day seven min 0.65cm, max 1.8cm, median 1.35cm; p=0.1157). Despite these significant differences from a statistical point of view, there are no differences which would lead to different age estimations of *L. sericata* as the observed variance in length appears to be negligible; however, the results suggest that it is possible to kill and store fly larvae directly in boiling 75% ethanol without using hot water beforehand. This simplifies the sampling and storing of fly evidence.

Forensic Entomology, Killing, Storage

H33 Optimization of a Method for the Extraction of DNA From Human Skeletal Remains

Sherri Deaton, BS, Western Carolina University, PO Box 2872, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the challenges regarding the recovery of amplifiable DNA from bone and the development of a method for maximizing DNA yield from bone while reducing the coextraction of inhibitory substances. Additionally, attendees will learn how the use of multiplex Polymerase Chain Reaction (PCR) and current-generation sequencing technologies to amplify and sequence the entire mitochondrial genome can increase the discriminatory power of mitochondrial DNA (mtDNA).

This presentation will impact the forensic science community by illustrating how maximizing DNA recovery from challenging bone samples with an efficient extraction method will allow for amplification and sequencing of the entire mitochondrial genome with decreased labor and cost than Sanger-type sequencing methods.

It is often challenging to obtain Short Tandem Repeat (STR) profiles from DNA extracted from bone as a result of the low amounts of nuclear DNA present or due to DNA degradation as a result of prolonged environmental exposure. Although STR profiling is preferred due to its discriminatory power, mtDNA analysis is often utilized in these cases. The matrilineal inheritance and lack of genetic recombination enables use of mtDNA to trace maternal lineages, which is particularly relevant in forensic casework in the absence of reference material; however, these attributes also limit the discriminatory power of mtDNA analysis.

The forensic community currently focuses on the analysis of the non-coding control region of mtDNA. The control region contains two hypervariable regions (HV1 and HV2), where the majority of differences between individuals are found. Shared polymorphisms present within the human mitochondrial genome are used to define haplogroups or population lineages. In some instances, it is challenging to discriminate between individuals who share polymorphisms in their hypervariable regions. Expanding analysis of mtDNA beyond the HV region has been shown to increase resolution of common haplogroups that are not resolvable with analysis of the HV regions alone.¹ A multiplex PCR approach has been developed that enables amplification of the entire mitochondrial genome in nine PCR reactions. This, combined with current-generation sequencing technologies, will allow for rapid generation of whole genome sequence data. Sufficient quantities of amplifiable mtDNA must be obtained to utilize this method.

An efficient extraction protocol is required to maximize DNA yield from bone samples while minimizing the coextraction of PCR inhibitors naturally present in bone, such as calcium and collagen. DNA extraction from bone can be thought of in three discrete steps: demineralization, lysis, and purification. Determining which lysis buffer is most effective for bone tissue is a critical first step in optimizing a method for DNA extraction from bone.

Two cross sections (2.5cm x 2.5cm) of bone tissue were excised from a human femur. The tissue was pulverized using a SPEX® 6770 Freezer/Mill®. Bone powder (0.1g) was demineralized using a chelating Ethylenediaminetetraacetic acid (EDTA) solution to disrupt the structural matrix of bone.² Resulting sequestered divalent metal cations were then washed away, and the remaining cellular material was incubated overnight in one of three different lysis buffers (buffers A-C). Lysis buffers A and B were purchased from commercial suppliers. Lysis buffer C is commonly used in forensic casework and is prepared in the laboratory. Lysates were purified using the QIAamp® DNA Mini Kit. Purified extracts were quantified using a human mtDNA quantitative PCR assay.³

Preliminary data suggests that buffer A exhibits consistent performance and often yields higher DNA recovery from bone samples than the other buffers studied, although additional work is needed to further refine these results. Furthermore, sample preparation methods appear to impact DNA recovery. A significant increase in yield was observed when polycarbonate components were used rather than stainless steel components during pulverization. Future method development will include evaluation of different purification methods, specifically the use of commercially available silica spin columns and magnetic bead-based purification systems. A final protocol will then be used to extract DNA from weathered skeletal remains, which will better represent bone specimens encountered in forensic casework. Maximizing DNA recovery will make whole genome mtDNA analysis possible which will result in greater discriminatory power of mtDNA sequence analysis.

H34 Engaging Undergraduate Students in Forensic Entomology Research: Life History Studies of Three Necrophilous Beetles

Erin J. Watson-Horzelski, PhD*, Southeastern Louisiana University, Dept of Biological Sciences, SLU Box 10736, Hammond, LA 70402

The goals of this presentation are to provide attendees with: (1) knowledge of the development times of two carrion beetle species, *Oiceoptoma inaequale* (F.) and *Necrodes surinamensis* (F.) (Coleoptera: Silphidae) at four constant temperatures; (2) instar determination of the hairy rove beetle, *Creophilus maxillosus* (L.) (Coleoptera: Staphylinidae); and, (3) the value of undergraduate research experience and mentorship in forensic entomology.

This presentation will impact the forensic science community by demonstrating the importance of understanding biological and life history data of common necrophilous beetles collected at a crime scene as well as by emphasizing the need for undergraduate research experience for all students interested in pursuing careers in forensic science.

Insects are poikilotherms (i.e., cold-blooded animals); thus, their growth and development rates are temperature-dependent. Furthermore, the summation of degree hours (thermal units) at a crime scene can be used to predict the overall energy budgets required to complete specific life stages of necrophilous insects present on human remains; however, entomologists must have access to published development data and the species-specific development thresholds for growth (min/max) in order to estimate postmortem intervals based on accumulated degree days. Development data are available for various forensically important fly species belonging to families such as Calliphoridae, Muscidae, and Sarcophagidae. There is limited-to-no controlled, laboratory-derived data available for predatory beetles commonly collected at decomposing remains (e.g., Histeridae, Silphidae, and Staphylinidae).

Watson-Horzelski determined the time of development and survivorship per life stage of the hairy rove beetle, *Creophilus maxillosus* (L.).¹ Following the same rearing protocol, development times were established for two carrion beetle species, *Oiceoptoma inaequale* (F.) and *Necrodes surinamensis* (F.) (Silphidae). Both species are common scavengers and predators of fly eggs and larvae associated with human cadavers and wildlife carcasses. Development studies were conducted at four constant temperatures (16°C, 20°C, 24°C, and 28°C) using a Caron Products® Insect Growth Chamber (Model 6025-1). All study specimens were maintained at 50% relative humidity and a 12:12 hour light:day photoperiod. All immature insects (egg, 1st, 2nd, and 3rd instar, and pupal life stages) were reared in separate containers and inspected twice daily (eggs) or daily (all remaining life stages) for survival, embryo development, time of molt, pupation, and adult emergence. Larval molts to progressive instars were determined by changes in cranial and pronotal width of the silphid larvae and confirmed by the presence of exuvia (cast skin) of the previous life stage.²

Identification of the correct life stage is critical in forensic entomology and for the estimation of time since death. Instar determination for the hairy rove beetle, another common predator of fly eggs and larvae, was performed according to protocols established by Watson and Carlton.² Study specimens of *C. maxillosus* were removed from Southeastern Louisiana University's Forensic Entomology Laboratory colony at known instar stages and preserved in 95% Ethanol (ETOH) (i.e., a total of 144, 153, and 208 1st, 2nd, and 3rd instars, respectively, were selected for the study). Morphological measurements included maximum cranial width, maximum pronotal width, and total body length (anterior margin of clypeus to tip of tenth abdominal segment). All measurements were performed under a Leica® MZ-16 stereomicroscope using digital calipers. The knowledge gained from both of these studies (morphological and development data) will enhance the ability to estimate time since death by providing additional life history information for three common predatory beetles present at the crime scene.

Forensic Entomology, Postmortem Estimation, Beetles

Pathology/Biology Section - 2015

H35 Effects of Amitriptyline on the Development of *Megaselia Scalaris* (Diptera: Phoridae) and Implications on the Estimation of the Minimum Postmortem Interval

Esta Bostock, BSc, University of Huddersfield, Queensgate, Huddersfield, West Yorkshire HD1 3DH, UNITED KINGDOM; Emma Lomas, University of Huddersfield, Queensgate, Huddersfield HD1 3DH, UNITED KINGDOM; Peter David Maskell, PhD, University of Huddersfield, Queensgate, Huddersfield, Yorkshire HD1 3DH, UNITED KINGDOM; Valentina Bugelli, MD, Institute of Legal Medicine, via Roma 55, Pisa 56126, ITALY; and Stefano Vanin, PhD, Queensgate, Huddersfield HD1 3DH, UNITED KINGDOM*

After attending this presentation, attendees will have novel information about the effect of amitriptyline, a tricyclic antidepressant commonly used in cases of major depressive disorder with a high toxicity in cases of overdose, on the development of a forensically important indoor species, *M. scalaris*.

This presentation will impact the forensic science community by offering new data on entomotoxicology.

The study focuses on amitriptyline, a tricyclic antidepressant, never tested in Phoridae. The last data about effects of this molecule on forensically important flies, such as Sarcophagidae and Calliphoridae, were published in the 1990s.

In forensic entomology, the estimation of the age of the insects is used for the estimation of the minimum Postmortem Interval (mPMI). Insect development rate is mainly temperature dependent despite other parameters like photoperiod, overcrowding, and food availability. In addition, several studies demonstrated that drugs and other chemicals can affect the growth of larvae feeding on the dead body, leading to incorrect mPMI estimations.

Amitriptyline is a commonly used antidepressant in cases of major depressive disorder. It is a tricyclic molecule absorbed in the gastrointestinal tract and metabolized in the liver. This molecule shows a high toxicity in cases of overdose.

Studies on the effect of amitriptyline on insect development and accumulation/excretion have been performed in the 1990s on *Parasarcophaga ruficornis* (Diptera: Sarcophagidae) and on *Calliphora vicina* (Diptera: Calliphoridae) whereas no data are available for other taxa. The results of these studies demonstrated no effect of the molecule on the growth rate. During the same time period, amitriptyline and derivatives were isolated from empty puparia of *Megaselia scalaris* (Diptera: Phoridae) and from skin and fecal material of *Dermestes maculatus* (Coleoptera: Dermestidae) collected from a mummified body in New England.

The goal of this study was to investigate the effect of amitriptyline, often found in cadavers, on the development of *Megaselia scalaris*, a common species found on indoor cases both in Europe and in the United States. This species is very important for mPMI estimation in indoor cases, as observed in this study and reported in the specific literature.

Larvae of *M. scalaris* were reared on pork liver with four different concentrations of amitriptyline (0=control, 120, 240, 800ng/g). One hundred twenty larvae per each concentration were killed in hot water after 48 and 72 hours from the experiment beginning (eggs) and measured using a stereomicroscope equipped with a camera and microscope imaging software with an automatic calibration of the measurements. Pupa and wing measurements were also collected and analyzed.

Statistical tests (one-way and factorial Anova, Tukey post-hoc) were performed using microscope imaging statistical software, using 0.05 as significant level.

Statistically significant differences were observed in the larval size of the four treatments after 48hrs and 72hrs ($F_{3, 476}=62.59$ $p=0.000$; $F_{3, 476}=13.66$ $p=0.000$, respectively). The same result was obtained for the pupa length ($F_{3, 476}=12.42$ $p=0.000$).

The wing size, used in order to detect differences in size in the adults, shows statistically significant differences ($p=0.000$) with the control being smaller when compared to the specimens fed on food with different antidepressant concentrations.

Durations of the immature stage (larval and puparial stages) despite the size differences were not statistically different from the control at all the tested concentrations.

In conclusion, this experiment demonstrated that for *M. scalaris* amitriptyline has an effect on the larval size but not on the total immature developmental time, so the mPMI estimation can be affected if based on the larval size and not on the complete development.

Entomotoxicology, mPMI, Forensic Entomology

H36 Spatial and Temporal Variability in Soils — Their Importance for Intelligence and Forensic Application

Natalie Damaso*, 6151 W 22nd Lane, Hialeah, FL 33016; Yu Cheung, BSc, Florida International University, 11200 SW 8th Street, Miami, FL 33199; and DeEtta Mills, PhD, Florida International University, OE 167, Biological Sciences, 11200 SW 8th Street, Miami, FL 33199

After attending this presentation, attendees will understand the potential of soil metagenomic profiling for determination of soil provenance. This presentation will illustrate the microbial patterns, specifically their spatial and temporal variability, in the soils while demonstrating to attendees the effectiveness of using microbial profiling compared to abiotic information for forensic applications.

This presentation will impact the forensic science community by demonstrating the potential of soil metagenomic profiling to assist in the identification of the soil's geographic location. This presentation will demonstrate the spatial and temporal variability of both biotic and abiotic data in soil, thereby illustrating the effectiveness of soil biotic data for use in forensic applications.

A vast array of information, both abiotic and biotic, is associated with soils. The current ecological hypothesis is that soil type (i.e., chemical/physical properties) is correlated to the community of microbes that inhabit that particular soil type.¹ Therefore, soil metagenomic profiling should produce a distinguishable biotic profile from a specific soil type from a particular geographic location and subsequent DNA and bioinformatics analyses of the soil community could provide a rapid method for soil provenance; however, the intrinsic spatio-temporal heterogeneity of soil also needs to be considered in the community analyses.² Microbial patterns as well as the spatial scale relationship between microbial community composition and environmental variables are largely unknown and it is important to understand these interrelationships for both ecological knowledge and for forensic applications.³ Microbial profiling effectiveness is dependent on the uniqueness among different habitat types, level of heterogeneity within a habitat, and stochastic processes in community over time.

In this study, bacteria, archaea, fungi, and plant universal DNA markers were polymerase chain reaction-amplified, separated by capillary electrophoresis and queried across six soil types in Miami-Dade County, FL, over two seasons (dry and wet; 2010-2011) and again four years later (2014). Abiotic information such as pH, inorganic/organic matter content, content, soil texture (% sand, % silt, % clay), and moisture content was obtained from the soil. Modeling approaches using geographic information systems were employed to study the soil processes and patterns by observing their spatial and temporal distribution using both abiotic and biotic information. The range of the various parameters across seasons (e.g., moisture content: dry=12.69-57.83%; wet=14.26-70.19%; pH: dry=7.15-7.94, wet=6.90-7.73) were correlated to the geographic location and soil type from which they were sampled. For the 2014 dry season, organic content ranged from 6.01%-38.31%, inorganic from 61.67%-93.99%, and carbon 3.01%-19.16%. The organic/inorganic and carbon data are pending for the 2014 wet season.

Soils should display limited temporal variability, in that soils should not change substantially over time, to be able to use pattern modeling for forensic or provenance applications. Bioinformatic algorithms (i.e., random forests and decision trees) were able to classify soils from a particular geographic location with >98% accuracy. The data from this study will add to that soil classification database and will be assessed for the ability to classify soils collected four years apart. These data then strongly verify the use of microbial profiling for provenance of soil.

Pathology/Biology Section - 2015

H37 SIDS, SUID, and Sudden Death in the Young: Where Do We Stand Today?

Wendy M. Gunther, MD*, OCME, Tidewater District, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510-1046

After attending this presentation, attendees will: (1) recognize factors from scene investigation, history, and autopsy which may help in identifying subsets of Sudden Unexpected (or Unexplained) Infant Death/Sudden Infant Death Syndrome (SUID/SIDS) in which the cause and manner of death can be given definitively; (2) understand subsets in which death certification contains uncertainty; and, (3) look forward to research and public health measures which may reduce the incidence of sudden unexpected death in infancy and increase understanding of the cause and manner in some infant deaths.

This presentation will impact the forensic science community by increasing understanding of the reasons behind the historical definition and changing evaluation of SIDS and SUID deaths. Attendees will look forward to future developments in understanding sudden death in the young and in certifying infant deaths.

This presentation briefly reviews the history of forensic medical opinion, and possible future developments, in the cause and manner of death in sudden unexpected deaths in infancy.

SIDS (“crib death”) has been under investigation for more than 40 years. During the decades of active research, numerous mechanisms of death have been proposed, many of which did not translate into clinical success in prevention. The most successful strategy, since its proposal by the American Academy of Pediatrics Task Force on Infant Sleep in 1992, has been supine positioning (“Back to Sleep”). Although the mechanism of underlying vulnerability in the triple-risk model is not understood, it is now universally agreed that babies are less likely to die suddenly and unpredictably in the first months of life if laid face up to sleep.

The advent of doll-scene reenactment provided startling evidence that some of the decrease in death rates was due to prevention of accidental suffocation in unsafe infant sleep conditions. As this was acknowledged in the forensic medical community, particularly after the Centers of Disease Control and Prevention (CDC) began to train death scene investigators in doll-scene reenactment, part of the ongoing decline in SIDS incidence was due to reclassification of many infant deaths as due to either asphyxia from accidental suffocation or SUID. SUID, often with the manner undetermined, is certified in infant deaths in which scene factors may play a role but the role cannot be determined definitively. This may include deaths during bed sharing with siblings, parents, and others; deaths in soft bedding which may result in suffocation; and deaths on sleep surfaces that are unsafe for small infants, such as couches, air mattresses, and beds intended for adults. The CDC now considers SIDS to be a subset of SUID.

Analysis of consecutive cases of SIDS/SUID examined over a two-year period in the Tidewater District branch of the Office of the Chief Medical Examiner reveals a continuum of cases ranging from unquestionable accidental suffocation, through suspected but unproven suffocation, to clear SIDS. Review of these cases suggests a considerable component of accidental suffocation in the majority of these infant deaths. Examination of the occurrence rate of SIDS/SUID in the different health districts of Virginia suggests that prenatal and postnatal training in safe sleep may have a significant effect on the incidence of SUID/SIDS.

Deaths in which parental training makes no difference may be those in which the mechanism of death is not related to suffocation. Despite research into brainstem receptors, ion channel abnormalities (some with long QT interval), defects in normal arousal systems, and different genetic alleles for metabolizing nicotine, the mechanism of death, if it is not accidental suffocation, is still not understood. The role of accidental suffocation, except in the most obvious deaths, remains unclear. At this time, often the best medical judgment is used to give parents whatever answers are available, without sufficient data to feel certain of the diagnosis.

The involvement of the CDC in the development of a Sudden Death in the Young database offers the possibility of separating out subsets of SUID, defined by testing, which would give definitive postmortem diagnoses. The database is still in its earliest stages and is still reliant on medical judgment in an area where judgment alone may not always be sufficient. As data accumulates and is analyzed, hopefully the future may see further decreases in deaths in infancy and more accurate certification of the deaths that do occur.

SIDS/SUID, Death Certification, Sudden Death in the Young

Pathology/Biology Section - 2015

H38 Deaths Due to Child Abuse: A Five-Year Review of Cases in the Cook County Medical Examiner's Office

*Serenella Serinelli, MD**, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena 336, Rome, Lazio 00169, ITALY; *Ponni Arunkumar, MD*, Cook County MEO, 2121 W Harrison Street, Chicago, IL 60612; *James A. Filkins, MD, JD, PhD*, 2121 W Harrison Street, Chicago, IL 60612; and *Lorenzo Gitto, MD**, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY

After attending this presentation, attendees will have a better understanding of the incidence and the significance of the injuries observed in fatal child abuse cases.

This presentation will impact the forensic science community by providing a review of the pattern of injuries in deaths due to child abuse.

Deliberately inflicted pediatric injuries are a significant issue in forensic pathology, with special regard to head injuries. Often questions arise regarding the plausibility of possible mechanisms of injury. This study reviewed case files from the Cook County Medical Examiner's Office from 2007 to 2012 to study the characteristics of homicides due to child abuse in children less than three years of age. The manner of death was determined to be homicide based on the autopsy findings and the investigation.

The cases were divided into the following age ranges: 0-11 months (group A); 12-23 months (group B); and, 24-35 months (group C). Data regarding age; race; sex; facial injuries; scalp injuries; presence and types of skull fractures; suture diastasis; extradural, intradural, subdural, and subarachnoid hemorrhages; cerebral edema; intracranial pressure; intracerebral findings; retinal and optic nerve hemorrhages; spinal cord findings; and extracranial injuries were collected using an electronic spreadsheet. Clinical details and information concerning the traumatic mechanism, where available, were also considered.

Fifty-one cases (25 females and 26 males) were identified. Most of the cases fell into the group A (26 cases; 51%), followed by group B (17 cases; 33%), and by group C (8 cases; 16%). Females were more numerous than males in group A (15 cases; 57%); in group B, males were more numerous (11 cases; 65%); in group C, children of both sexes were present in equal number.

External signs of impact to the head, that is to the face and/or scalp, were present in 42 cases (82%). Most of the examples of impact to the head consisted of bruises and abrasions of the skin and/or lacerations of the oral mucosa. Skull fractures were reported in 9 cases (18%), and showed a predominately linear appearance. Diastasis of the sutures was reported in 14 cases (27%). As might be expected, most of these examples were found in the youngest age range. Epidural hemorrhage was found in 10 cases (20%). Subdural hemorrhage was seen in 42 cases (82%). Subdural hemorrhage represented the most common intracranial pathology encountered, apart from cerebral edema, which was found in each case. Subdural hemorrhage was described as remote or recent, and/or with a thin film or layer of blood or a larger collection of blood. Subarachnoid hemorrhages were present in 27 cases (53%).

In 24 cases (47%), there were intracerebral findings, such as hemorrhages, contusions, herniations, and areas of infarction. In eight cases (16%), brain evaluation was affected by marked non-perfusion changes (so-called "respirator brain"). Retinal hemorrhages were a very common finding in head trauma (38 cases, 75%). Most were bilateral and sometimes involved multiple layers of the retina (preretinal, intraretinal, subretinal). Optic nerve hemorrhages were present in 37 cases (73%). Intravitreal hemorrhages and macular folds were rare. In 19 cases (37%) there were spinal cord injuries, such as hemorrhages, but no spinal fractures were observed.

This study reveals that in the cases surveyed, the majority of children who sustained abusive injuries fell into the 0-11 months of age range. Head injuries were the leading cause of death. Signs of impact to the head defined by the presence of skull fractures and/or bruises/abrasions to the head, often together with intracranial injuries, were present in 73% of the cases (19 out of 26) in group A, 94% (16 out of 17) of the cases in group B, and 88% (7 out of 8) of the cases in group C. As expected, epidural hemorrhages were rare and spinal fractures were not observed at all.

Death due to extracranial injuries was an uncommon finding and it occurred when internal organs were damaged. Among these, blunt force abdominal injuries were the most commonly encountered (10 cases; 19%).

These findings agree with other researchers who have found that head injuries are the leading cause of death in children less than three years of age. Moreover, in the cases reviewed for this study, retinal hemorrhages seemed to be strictly associated with head injuries.

Child Abuse, Head Injury, Homicide

H39 Reclassification of Sudden Infant Deaths in New Mexico

Lauren E. Dvorscak, MD*, University of New Mexico Hospitals, MSC08-4640, 1 University of New Mexico, Albuquerque, NM 87131; Sarah Lathrop, DVM, PhD, Office of the Medical Investigator, 1 University of New Mexico, MSC 07 4040, Albuquerque, NM 87131; and J. Keith Pinckard, MD, PhD, Office of the Medical Investigator, MSC07 4040, 1 University of New Mexico, Albuquerque, NM 87131-0001

After attending this presentation, attendees will understand the complexities surrounding the certification of unexplained infant deaths. Attendees will learn how changing classification schemes have impacted the downward trend of infant deaths after the introduction of the “Back to Sleep” campaign in New Mexico. Additionally, attendees will be able to apply knowledge gained to augment and standardize the practice of coding sudden infant deaths.

This presentation will impact the forensic science community by the presentation of a collaborative effort in reclassification of infant death in New Mexico and how this has impacted appropriate coding and standardization of these cases, particularly taking into account the diagnostic shift in manner of death. Standardization in coding necessitates that medical death investigators are familiar with the changing classification scheme and the implications for statistical tracking of infant death cases.

Background: The classification “Sudden Infant Death Syndrome” (SIDS) was coined to place sudden unexpected deaths of infants with no apparent cause of death into a category of exclusion to facilitate research. In practical use, the classification became a diagnosis, implying that SIDS was due to underlying disease processes; however, as scene investigation improved, forensic pathologists have realized that this is a far more heterogeneous group, consisting of cases of undiagnosed natural diseases, accidental suffocations associated with unsafe sleep environments, and covert homicides. Infant deaths certified as SIDS have decreased, in the decade surrounding the implementation of the American Academy of Pediatrics’ “Back to Sleep” Campaign introduced in 1994. As this decline represented a decrease in the number of accidental asphyxia deaths, it demonstrates that these deaths were erroneously being classified as SIDS. The other reason for the decline in SIDS death certifications is also obscured by a diagnostic shift from SIDS to “undetermined.”

Purpose: The intent of this study is to determine the extent of variation in certifying sudden unexpected infant deaths that exists among pathologists at a statewide medical examiner’s office and to investigate the changing trends of certifying these deaths in New Mexico.

Methods: A computerized query of all infant deaths less than one year of age between 2006 and 2011 yielded 134 cases originally certified as SIDS, Sudden Unexplained Infant Death (SUID), asphyxia, suffocation/strangulation, and undetermined. Scene, autopsy, and ancillary testing data were extracted from electronic and paper records and summarized into reports with accompanying scene and autopsy photographs when available. Nine forensic pathologists blinded to the original certification rendered a new cause/manner of death using current conventions. New diagnoses were compared to the original diagnoses as listed in the computerized records system and their corresponding ICD-9 coding by the Bureau of Vital Statistics using inter-observer agreement analysis (kappa statistics).

Results: The 134 study cases fell into three broad, original diagnosis categories: SIDS/SUID (66 cases), asphyxia/suffocation (23 cases), and undetermined (45 cases). Study population demographics demonstrated that 56.7% of the cases involved co-sleeping with an adult and 31% of cases were positioned prone to sleep.

When compared to original certification, a diagnosis of SIDS was not rendered by any pathologist in the study. All 66 cases originally coded as SIDS were classified to alternatives such as suffocation/strangulation or undetermined, with rare exceptions by three different pathologists involving natural deaths due to infectious causes or congenital anomalies. The pathologists reclassified more SIDS cases as undetermined (range 30-50 cases between pathologists) than as asphyxia/suffocation (range 14-34 cases between pathologists). Of the 23 cases originally called asphyxia/suffocation, most remained as such (range 8-21); however, some pathologists reclassified them as undetermined (range 2-15). The 45 undetermined cases largely remained undetermined (range 23-40), yet many were reclassified as asphyxia/suffocation (range 5-19), infectious (range 1-3), or as due to other causes (1).

Overall, poor agreement was observed between study pathologists and the original cause of death assigned to the infant deaths, with kappa statistics ranging from -0.15 to -0.01. The comparison of assigned manner to the originally assigned manner resulted in slightly better agreement, with kappa statistics falling in the “slight” to “fair” classifications of 0.08-0.18. When comparing certifications between reviewing pathologists only, moderate agreement was identified between the most experienced and the most junior pathologists, with a kappa of 0.46 and 0.42 for cause and 0.45 and 0.46 for manner.

Pathology/Biology Section - 2015

Conclusions: The practices of certifying SUIDs have shifted significantly over time, which may account for a large proportion of the decline in deaths certified as SIDS. Although poor inter-observer agreement existed between the original and reviewing pathologists in this study, no reviewing pathologist coded any study case as SIDS/SUID, accurately reflecting a diagnostic shift in the field. This study demonstrates the importance of consistency in the approach to certifying unexplained infant deaths.

H40 A Re-Examination of Patterns of Abuse in Children

*Gina O. Hart, MA**, Regional MEO, 325 Norfolk Street, Newark, NJ 07103-2701; *Steven A. Symes, PhD*, Mercyhurst College, Mercyhurst Archaeological Institute, 501 E 38th, Erie, PA 16546; and *Roger A. Mitchell, MD*, Regional MEO, 325 Norfolk Street, Newark, NJ 07103

After attending this presentation, attendees will recognize the importance of anthropological skeletal analysis in pediatric cases and the recognition of fracture patterns associated with Non-Accidental Injuries (NAI) in children, including spiral fractures in long bones.

This presentation will impact the forensic science community by supporting the need for the combination of forensic pathology with trauma anthropologists during autopsy, expanding the definition of injuries associated with NAI, and reinforcing the need for a comprehensive understanding of bone biomechanics and the total trauma pattern.

The recent inclusion of in-house forensic anthropologists in medical examiners' and coroners' offices has evolved trauma anthropology. Trauma anthropologists use their training in human skeletal anatomy, biomechanics, and trauma interpretation in fresh autopsies to recognize and decipher the patterns associated with fracturing, allowing for a complete view of injury patterns. In pediatric cases, trauma anthropologists have revealed fracture patterns associated with NAI that may be overlooked in digital images and the forensic pediatric autopsy. Examination of the underlying bone by a trauma anthropologist is a key component to fully illustrating all injuries in pediatric cases. Fracture patterns associated with NAI include Classic Metaphyseal Lesions (CML), posterior rib fractures, complex skull fractures, and multiple fractures of varying ages.^{1,2} Spiral fractures are not accidental as some research suggests, rather they may be non-accidental patterns in all cases, and especially in non-weight bearing bones and when the child is not independently mobile.³

Biomechanical interpretations reveal how bone behaves as a material as well as to how bones behave in life; factors vital in understanding skeletal injuries.⁴ Spiral fractures specifically are a result of torsional forces acting in tension and shear on the movable (non-stable) end of the bone. Understanding biomechanics, fracture production, and directionality of fracturing allows for the anthropologist and the pathologist to understand events surrounding and leading to death.

A case of a four-month-old male is presented as an example of trauma anthropology contributions to autopsy findings. The case originally came to the medical examiner's office as an infant found unresponsive in his crib. The pathologist found multiple acute posterior rib fractures at autopsy and requested an anthropological examination of the injured ribs and all long bones to examine for CMLs. The anthropologist observed the previously noted posterior rib fractures, but also discovered undiagnosed injuries including sternal rib end fractures, evidence of healing rib trauma, and two acute spiral fractures to long bones. The latter injuries contributed to the pathologist's findings by providing a better understanding of a pattern of non-accidental inflicted trauma. The pair of spiral fractures in long bones represent severe and duplicated trauma to an infant and the healing rib fracture establishes a pattern of abuse. These findings are "enablers" for a child abuse investigation, scrutiny of caregivers, and eventual prosecution in cases of demonstrated abusive behavior. While everyone wants to believe the caregivers' story in a child death case, a total body trauma examination may substantiate or change an accidental death to a suspicious death or homicide. In this case, an immediate confrontation with caregivers culminated in a full confession of the mother, with specific accounts of the lethal event.

This presentation will discuss the biomechanics behind the creation of NAI and, in particular, spiral fractures and their omissions in literature as patterns associated with NAI in children. Obviously, the team approach between coroners, forensic pathologists, and trauma anthropologists is suggested in order to diagnose injuries that may be overlooked when a skeletal survey is not routinely conducted on infant deaths.

Pathology/Biology Section - 2015

H41 Autopsied Cases of Suspected Child Abuse Showing Absence of Clinically Diagnosed Injuries

Ronald K. Wright, MD, JD*, 1000 Ducks Nest Road, Turtletown, TN 37391

After attending this presentation, attendees will understand that all that glitters is not gold when it comes to pediatrician-diagnosed child abuse.

This presentation will impact the forensic science community by exposing myths of pediatrician diagnoses of child abuse.

Unfortunately, child abuse cases occur, usually at the hands of the boyfriend of the child's mother. These cases are generally easily diagnosed and classified.

The forensic pathology cases investigated from 2010 to July 2014 total 420. The cases labeled as child, meaning newborn to age 12, number 34 or 8.1 % of the cases investigated. Of these, one was performed for the prosecution and 33 were for the defense. Of these 34 cases, ten were characterized by absent or trivial subgaleal hemorrhage, positive subarachnoid hemorrhage, positive subdural hemorrhage, and encephalomalacia. Two cases were diagnosed as having skull fractures in life, none of which were demonstrated at autopsy. Two cases were diagnosed as having "classic bucket handle metaphyseal fractures," none of which were demonstrated at autopsy. The remaining 24 cases revealed evidence of child battery including ruptured jejunum, multiple blunt impact injuries to the head and other areas, or non-accidental burn injuries.

Resuscitation by closed chest cardiac massage was first described by W.B. Kouwenhoven et al. in 1960. In 1964, Wilder reported on training ambulance personnel in the technique and reported no injuries. This was followed by legislative action which brought cardiopulmonary resuscitation to almost all areas of the United States by 1970.¹⁻³

In 1971, A.N Guthkelch wrote in the *British Medical Journal* that infants without evidence of subgaleal hemorrhage had subdural hemorrhage. Citing the work of Ommaya, he proposed that non-impact shaking could cause these injuries.^{4,5} As time has gone by, the three primary signs ("triad") of shaken baby syndrome have become entrenched in the medical literature and in pediatricians' training. The appearance of retinal hemorrhage, subdural hematoma, and encephalomalacia diagnosed in life has become the hallmark of criminal child abuse and has caused many caretakers and/or parents to be arrested and charged with a capital offense. In addition, Dr. Kleinman has written extensively and almost exclusively about the "classical metaphyseal fractures" seen in abused infants. Dr. Ayoub has written recently and criticized Dr. Kleiman's theories.^{6,7}

In this study, ten cases diagnosed in life and at autopsy are presented. Only one case had subgaleal hemorrhage and it was extremely small. Nine of the ten cases had no blunt impact injury to the skull as demonstrated by absent subgaleal hemorrhage. Two cases had clinically diagnosed classic metaphyseal fractures which were not demonstrated at autopsy. Two cases had clinically diagnosed skull fractures which were also not demonstrated at autopsy.

In spite of the negative autopsies, all ten deaths resulted in the prosecution of adult care takers, as abusive head trauma. Recommendations concerning proper autopsy techniques in suspected child abuse cases are presented. Suggestions concerning proper cause and manner of death statements are presented as well.

H42 Evaluation of Rib Fracture Injury Modes and Biomechanics in Abused Infants

Steven A. Symes, PhD*, Mercyhurst College, Mercyhurst Archaeological Institute, 501 E 38th, Erie, PA 16546; Ericka N. L'Abbe, PhD, PO Box 5023, Pretoria 0001, SOUTH AFRICA; and Erin Chapman, MS, 501 Kensington Avenue, Buffalo, NY 14214

After attending this presentation, attendees will understand the biomechanical principles underlying fracture patterns in the infant rib cage. Non-accidental rib fractures in children have been studied for decades, but the forensic application and interpretation of bone injuries is unclear due to variation in: (1) research methodology; and, (2) fracture visualization techniques in the radiographic, medical, and anthropological literature.

This presentation will impact the forensic science community by contributing to the knowledge of the biomechanics, modes of failure, and the patterns of injury in the infant rib cage, and the potential for the application of this knowledge in the diagnosis of rib fractures in cases of child abuse. Rib fractures in infants are often difficult to detect through radiographic images, so increased forensic anthropological knowledge on the subject can help anticipate Non-Accidental Trauma (NAT).

Rib fractures are pathognomonic for abuse in young children.¹ Violent squeezing, shaking, punching, or combinations of assaults are reported to predictably create failures in the posterior, anterior, and lateral arcs of the rib cage. Often, anterior-posterior compression is offered as an explanation of fractures to the rib heads and costotransverse processes as well as the anterior costochondral areas of infant chests; however, lateral fracture production in the chest remains unclear in the literature.² Many researchers include lateral arc fractures as part of the same anterior/posterior bending failure associated with shaking and compressive injuries.

To address this discrepancy in the literature, fracture patterns were observed in ten NAT infant rib fractures. Rib fractures were recognized at autopsy, removed, and examined in a dry state with a stereomicroscope. Bone failures were assessed in terms of tension and compression.

Posterior and anterior arc fractures are by far the most observed; lateral arc fractures were rare, despite their common mention in the literature. Tension failure in the rib heads occur anteriorly as the rib neck is levered over the transverse process; failure first occurs in the area where the rib head is thin yet firmly attached to the vertebra body. The same bending motion may also create fractures in the area of the transverse process articulation. The latter fractures react like bending long bones diaphyses, where bone is highly resistant in compression due to thickened cortical bone, so failure occurs initially in tension on the internal rib surface.

Anterior rib fractures are a dissimilar reaction of the chest to posterior rib fractures. The cortical bone of the front rib is thin and trabecular bone is prominent. The structure is similar to bone metaphyses and epiphyses, where bone is weak in compression but capable of repeated trauma. Buckle fractures occur in front rib shafts and damages to costochondral junctions are most often observed in circumstances of anterior/posterior compression where flexible bone fails initially in compression.

The commonly described lateral arc failure scenario would suggest failure with compression internally and tension externally; however, if midshaft rib failures are more commonly associated with direct impacts, the biomechanics of failure should demonstrate the opposite direction of bending (i.e., an impact to lateral ribs would initially fail internally in tension). This lateral scenario appears to be a likely consequence in the non-accidental bone injury cases observed.

The recognition of tension/compression bone failure confirms the mode of bone bending and goes beyond spatial recognition and stereotypic explanations for rib fractures. Assessing skeletal injuries from a biomechanical perspective reveals specific relationships of bone injuries and conceivably facilitates the evolution of bone trauma interpretation as a scientific discipline. Therefore, fresh and healing fractures may reveal additional information concerning skeletal element failure. In the current study, lateral rib fractures appear to be rare and not a result of anterior-posterior squeezing.

H43 Rebleeding Into Subdural Neomembranes and the Myth of “Two in a Row” in Childhood

Nea D. Moyer, BS*, University of Maryland, Baltimore, 22 S Greene Street, Baltimore, MD 21201; John A. Bechinski, DO, Forensic Pathology, 1215 E Michigan Avenue, Lansing, MI 48912; and Rudy J. Castellani, MD, Department of Pathology, 22 S Greene Street, Baltimore, MD 21201

After attending this presentation, attendees will gain an understanding of subdural neomembranes, their rebleeding tendency, and their relevance in unexplained deaths in childhood.

This presentation will impact the forensic science community by enhancing the knowledge of subdural neomembrane pathophysiology and providing an evidence-based assessment of the practical realities surrounding neomembranes in children, including the likelihood that the “two in a row” theory, or two accidental sublethal injuries, might explain a catastrophic neurologic event.

Whether small subdural collections or subdural neomembranes may predispose to rebleeding after minor head trauma is a point of debate in the criminal defense world.¹ Complicating the issue is the fact that chronic subdural collections by themselves in children have a significant likelihood of being caused by abuse, while rebleeding into chronic subdural collections is common in older age groups and may be encountered with trivial, or unrecognized, head injury. In effect, a traumatic lesion that is often non-accidental in children is used somewhat ironically as a means to lessen the culpability of potentially the same perpetrator who later inflicted an acute process that lead to catastrophic neurological collapse.

This issue is illustrated by the case of a 3-month-old boy who presented to the emergency department in a coma after falling off a couch onto a carpeted floor, per the father’s account. After initiation of resuscitative efforts, evaluation revealed acute subdural, subarachnoid, and intraventricular hemorrhages, bilateral retinal hemorrhages, and a healing right 11th rib fracture. The child was the product of a twin gestation; the twin was also found to have healing fractures. Despite resuscitative efforts, the infant continued to decline and expired after being declared brain dead. Autopsy examination revealed bilateral subdural and subarachnoid hemorrhages, bilateral retinal hemorrhages, a healing 11th rib fracture, diffuse cerebral edema with transient global ischemic necrosis, and a subdural neomembrane involving the falx cerebri. Minimal acute blood was associated with the neomembrane.

In this case, the accident as reported by the father was vigorously defended on the basis of the neomembrane, in effect indicating that the neomembrane facilitated the neurologic decline with trivial head trauma, consistent with a fall off a couch onto a carpeted surface.

In addition to this illustrative case, the pathophysiology of subdural neomembrane, subdural rebleeding, and accidental as well as non-accidental blunt trauma in children is reviewed, along with a review of the pediatric literature on acute and chronic subdural hemorrhage.

In conclusion, only rare cases of subdural neomembrane rebleeding are recorded in the literature, and no prospective data are available. Moreover, no cases of acute neurologic collapse due to rebleeding into a neomembrane have been described to date, suggesting that the “two in a row” theory does not occur in humans, as is often suggested at trial.

Pathology/Biology Section - 2015

H44 Intrauterine Liver Disease and Sudden Unexpected Infant Death: Causally-Related or Coincidence?

Peter J. Stephens, MD, 100 Club Drive, Ste 135, Burnsville, NC 28714*

After attending this presentation, attendees will understand the complexities of intrauterine liver diseases and specifically Gestational Alloimmune Liver Disease (GALD) in which transplacental maternal antibodies lead to fetal and neonatal liver disease with highly variable clinical and histopathologic features. Prior to recent understanding of the pathogenesis, liver transplantation was frequently required in order to save the lives of patients in whom the clinical diagnosis had been made antemortem.^{1,2} Attendees will be introduced to the forensic significance of this and related intrauterine liver disease as mimics of abusive injury and will understand the importance of making a correct diagnosis.

This presentation will impact the forensic science community by informing attendees of recent advances in the understanding of intrauterine and neonatal liver disease by discussion of three cases, all presenting as sudden unexpected infant death in which fathers were charged or convicted of murder. The presentation will emphasize the clinical features of the disease and its histopathologic features at autopsy. It will discuss the differential diagnosis of gestational alloimmune liver disease in the face of sudden unexpected death in infancy and its role as a natural disease mimicking inflicted trauma. Forensic pathologists will learn of simple and inexpensive ways of confirming or excluding the disease at autopsy in cases of sudden unexpected infant death.

Studies of abusive head injury by investigators in various disciplines over the past decade have confirmed the presence of numerous mimics of abusive head trauma. These mimics include natural disease as well as accidental injury. The differentiation of abusive trauma from its mimics is increasingly important in terms of the financial and human costs to society of the litigation and incarceration of the innocent.

Gestational liver disease has only been studied intensively for the last two decades and by relatively few institutions in the United States and Europe. At the present time, the understanding is incomplete and much basic research needs to be done in various areas.

This presentation will discuss the details of a series of three autopsy-confirmed cases of intrauterine liver disease which were accompanied by unexpected death under unusual circumstances in the first three months of life. Legal proceedings in two of the cases resulted in convictions with lengthy prison terms; the third resulted in acquittal. After reviewing the first of the three cases, the sensitivity to this diagnosis was heightened and two other cases were seen in the subsequent two-year period. In two of the three patients, terminal cardiorespiratory arrest had precluded any clinical investigation and in the third case the clinicians did not entertain the diagnosis due to its protean clinical presentation, resulting in minimal investigation prior to autopsy. In different published series, the clinical course of the disease has varied from benign or virtually asymptomatic to rapidly lethal. The associated liver findings have also been highly variable, ranging from little or no clinical evidence of liver disease with essentially normal liver histology through advanced liver disease with hepatic failure and/or cirrhosis. Biochemical testing (liver function tests) are also highly variable and normal transaminase levels are common. Likewise, blood ammonia levels are variable.

Abnormalities of iron metabolism appear to be the most common feature and prior to a decade ago was widely referred to generically as Neonatal Hemochromatosis (NH). The histological hallmark of NH was typically regarded as accumulation of storage iron outside the reticuloendothelial system and in epithelial cells in a variety of organs; however, reticuloendothelial iron may be seen in this disease and was the key initial finding in one of these three cases. The basic criterion for the diagnosis remains the presence of stainable iron in one or more of various epithelial tissues including liver, pancreas, thyroid, adrenal, and minor salivary glands.

In cases of sudden unexpected death in infancy, there is typically inadequate time for clinical investigation and therefore the diagnosis must be made on the basis of autopsy findings. These findings typically require an index of suspicion but are generally easily confirmed if appropriate iron staining is done. This presentation will recommend routine iron staining of liver, pancreas, thyroid, and adrenal medulla in all infants under six months of age. Even when the correct diagnosis is made, it may not be possible to define a specific linkage between the disease and death in any given case, making assessment of "reasonable doubt" difficult. This difficulty notwithstanding, it is important for the trier of fact to be given all of the information generated at the autopsy.

H45 Fatal Aortoesophageal Fistulae Due to Foreign Body Ingestion in Young Children: Presentation of Two Cases

Tasha Z. Greenberg, MD, Tarrant County MEO, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919; Susan J. Roe, MD, Tarrant County MEO, 200 Feliks Gwozdz Place, Fort Worth, TX 76104; David Stephen, DO, Tarrant County MEO, 200 Feliks Gwozdz Place, Fort Worth, TX 76104; and Nizam Peerwani, MD, Tarrant County OCME, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919*

After attending this presentation, attendees will understand how an aortoesophageal fistula may develop, the potential subtleties of clinical presentation, and will be aware of the hazards of ingesting coin batteries.

This presentation will impact the forensic science communities by increasing knowledge of the pathology of aortoesophageal fistulae and factors leading to their development. This knowledge may lead to greater public health awareness and prevention of deaths due to ingested objects, including coin batteries.

Foreign body ingestion is common in young children, with close to 80,000 cases reported to the American Association of Poison Control Centers' National Poison Data System in 2011. In the majority of cases, foreign body ingestion will not have an adverse outcome; however, it can lead to more serious consequences, including respiratory complications, esophageal erosions, or even an Aortoesophageal Fistula (AEF). In 2011, two deaths due to disc battery ingestion were reported in children under the age of five years.

At the Tarrant County Medical Examiner's Office in 2013 and 2014, two children less than two years of age with sudden onset of upper gastrointestinal hemorrhage and death were autopsied. Case 1 was a 14-month-old female in a store shopping cart who developed seizure-like activity and copious bleeding from the mouth prior to becoming unresponsive. At autopsy, two opposing round mid-esophageal ulcerations were present, with formation of an AEF. Blood was in the stomach and small bowel almost to the cecum. A foreign object was not identified. The child was evaluated by a pediatrician two weeks prior for vomiting and crying and was treated for bilateral otitis media. When she returned home, she was unable to swallow solid foods, though she could take liquids. This resolved within one week.

Case 2 was a 19-month-old male brought to an emergency room by a babysitter for blood coming from his mouth. A radiograph showed a foreign object in the stomach. The child died prior to transport to a tertiary care center. At autopsy, an esophageal ulceration with an AEF and a bronchoesophageal fistula were present, with blood and a large lithium coin battery present in the stomach. Three days prior to death, he was seen in an emergency room for a "barking" cough and was diagnosed with croup.

Esophageal foreign bodies as a group require early intervention because of their potential to cause complications, including erosion, periesophageal abscess, and fistula formation between the aorta and/or the tracheobronchial tree. Button or coin batteries are particularly hazardous due to their size and shape as they are easily swallowed and become lodged in the esophagus or airway. These batteries are used in many household items including flashlights, toys, watches, hearing aids, and remote controls. Lithium batteries generate current flow through saliva which hydrolyzes water, creating alkaline hydroxides that result in caustic tissue damage and rapid perforation. If untreated, AEF can lead to massive gastrointestinal hemorrhage with exsanguination, shock, and death as seen in both presented cases. A coin battery was found in the stomach in case 2. While no foreign object was found in case 1, the ulceration had characteristics similar to a round object. In retrospect, both children had prior symptoms of foreign body ingestion with partial obstruction that led to their evaluation by a physician; however, the diagnosis was not made. As evidenced by these cases, the presenting symptoms may be vague and easily confused with other common childhood illnesses. It is important for pediatric practitioners to be aware of the dangers of foreign body ingestion and the potential for formation of aortoesophageal fistulae, especially with the increased use of lithium coin batteries in household items.

Aortoesophageal Fistula, Foreign Body Ingestion, Coin Battery

Pathology/Biology Section - 2015

H46 Mortality Related to Falls From the Balcony of Children Younger Than 18 Years of Age

Fatih Sahin, Küçükçekmece/Istanbul, Istanbul, TURKEY; Abdurrahman Emir, Cobancesme Mah. Kimiz sok. No: 1, Council of Forensic Medicine, Yenibosna, Istanbul 34180, TURKEY; Erdinç Özdemir, The Council of Forensic Medicine, Ministry of Justice, Çobançesme Mah., Kimiz Sok.no:1 Bahçelievler, Istanbul, TURKEY; Safa Celik, Adli Tip Kurumu Baskanligi, Istanbul, TURKEY; Sermet Koc, Adli Tip Kurumu Morg Dairesi Baskanligi, Bahcelievler, Istanbul 34196, TURKEY; and Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104*

After attending this presentation, attendees will understand the importance of the prevention of childhood deaths due to falls.

This presentation will impact the forensic science community by providing data related to childhood deaths due to falls from balconies.

In this presentation, 32 cases from the Istanbul Morgue Department's archive of victims less than 18 years old who fell from balconies were analyzed and compared to other reports in the literature for age, sex, cause of death, time of year, hospitalization period, autopsy findings, toxicology results, and relevant social responsibilities. Similar to developed countries that rank falls as the fourth-leading cause of death in children, falls are a major problem in Turkey.¹ Falls account for 5.9% of all childhood deaths.² Childhood falls are the source of 25%-34% of emergency responses in Unites States.³ One study conducted in Turkey found that 11.9% of all deaths occurring between the ages of zero to ten years are the result of a fall from a balcony, with the percentage increasing each year.^{4,5} In a study by Yayci et al. in Istanbul, falls ranked fourth and represented 15.5% of all trauma-related deaths reported during 2001-2005.⁶

This study retrospectively analyzed 34 autopsies performed during 2008-2012 in the Istanbul morgue in which a fall resulted in the death of a child less than 18 years of age. This analysis included each victim's age, sex, cause of death, time of year, hospitalization period, physical findings at autopsy, and toxicological facts. Eighteen cases (52.9%) of the victims were female and 16 (47.1%) were male. The youngest victim was 11 months old and the oldest was 17 years, 11 months old. The cause of death in 31 (91.2%) of the cases was extensive body trauma and in three cases (8.8%) death was reportedly due to blunt force head trauma. While there was no information about the height of the building where 22 (64.7%) of the victims had fallen, there was documentation that five of the victims had fallen from the 5th-floor balcony. The lowest height was the first floor and the highest was reported to be a 7th-floor balcony. Distribution according to time of year when the deaths occurred showed the highest rate of falls occurred in summer (n=15) and the lowest in winter (n=4). The maximum duration of hospitalization was reported to be 33 days and 22 (64.7%) of the cases had no record of hospitalization at all. Toxicological examination was insignificant in 20 (58.8%) of the cases while three (8.8%) cases were positive for therapeutic levels of medication; one (2.9%) case was positive for ethanol and one (2.9%) was positive for n-butane.

Many studies have concluded that the reason for an increase in fatalities due to falls during the summer months is because children use balconies more often during the warm season.⁷ Reports prepared by American Academy of Pediatrics Committee on Injury and Poisoning Prevention discuss in detail measures and recommendations on ways to reduce falls from windows, balconies, and rooftops.⁸ From a social perspective, to reduce the number of fall-related deaths, various public-awareness training programs should be prepared. Additionally, building-code regulations related to safety should be broadened and enforced.

H47 Shaken Baby Syndrome/Abusive Head Trauma: An Ongoing Debate Not Yet Resolved

Antonio Oliva, MD, PhD, Largo Francesco Vito 1, Rome, ITALY; Vincenzo M. Grassi, MD, Catholic University, School of Medicine, Largo F. Vito 1, Rome 00168, ITALY; Valentino De Matteis, MD, Catholic University, School of Medicine, L.go Francesco Vito 1, Rome 00168, ITALY; Antonio Marcelli, MD, Catholic University, School of Medicine, L.go Francesco Vito 1, Rome 00168, ITALY; and Riccardo Rossi, MD, Largo Francesco Vito 1, Rome, ITALY*

After attending this presentation, attendees will understand the main diagnostic criteria of shaken baby syndrome or abusive head trauma (the preferred term). Emphasis will also be placed on the ongoing challenge in everyday forensic practices when faced with ambiguous cases requiring a differential diagnosis between either an abusive or a resuscitative shaking of a baby.

This presentation will impact the forensic science community by promoting a multidisciplinary approach to clarify the pathophysiologic mechanism in explaining the nature of the injuries and establishing definitive signs to reach the most reliable diagnosis according to the clinical history and parental interview.

This study will present the case of a 5-month-old female baby who was found unconscious on the floor by her father after accidentally falling from the crib. The father immediately tried to resuscitate the baby by violently shaking her after grabbing her thorax and arms. The attempt to resuscitate failed and the man took his daughter to the Emergency Department (ED) where she arrived unconscious. On admission to the ED, the baby presented with an ecchymosis on the left hemi-thorax, an abrasion on the right arm, bilateral retinal hemorrhages, and subarachnoid hemorrhage involving the frontal lobes and around the tentorium. A medicolegal assessment was requested to establish if the case was suitable for referring the matter to the state prosecutor's office.

Shaken baby syndrome is a type of abusive or non-accidental head trauma that occurs when a child is violently shaken and therefore acceleration/deceleration/rotational forces are impressed on the victim's body, with or without impact. In the last decades, "shaken baby syndrome" has been one of the most used terms in pediatrics; however, the preferred term is now "Abusive Head Trauma" (AHT), which is defined as an injury to the skull or intracranial contents of an infant or young child (<5 years of age) due to inflicted blunt impact and/or violent shaking. Despite the wide range of clinical manifestations, AHT has classically been diagnosed by the presence of the so-called "triad," characterized by subdural hemorrhage, retinal hemorrhage, and neurological dysfunction. These three major clinical findings may be associated with various non-specific clinical signs such as skin lesions and bruising, bone injury mainly involving the ribs, and injuries to the neck muscles, the spine, or the spinal cord.

In the presented case, the medical history and interview were of concern to the physicians, especially as the father admitted shaking the baby in an attempt to resuscitate his daughter. Indeed, the clinical findings were suggestive of shaking. Moreover, innocent shaking related to resuscitation of an unconscious or semiconscious baby in an attempt to stop seizures, prevent suffocation, or waken a sleeping baby is reported in the literature.

Distinguishing between a real wrongdoing and an innocent action is often difficult from a clinical and forensic point of view. The main consequence of this differential diagnosis is represented by the decision to refer the matter to the state prosecutor. In any case, the "absolute proof" of abuse is not necessary to report an event to the state prosecutor's office. In the case presented, the severe neurological dysfunction sustained by the patient and the ambiguous anamnestic data, together with the referred accidental fall, justified reporting the episode to the state prosecutor's office.

Shaken Baby Syndrome, Abusive Head Trauma, Report to the State Prosecutor

H48 Do the Eyes Have It? Traumatically Induced Primary Optic Nerve Sheath Hemorrhage

*Erik K. Mitchell, MD**, 40 S 18th Street, Kansas City, KS 66102; and *Stephen R. Roseborough, BA*, Kansas Bureau of Investigation, 821 N Broadway, Pittsburg, KS 66762

After attending this presentation, attendees will understand the possibility of the generation of optic nerve sheath hemorrhage without neck fracture, skull fracture, brain hemorrhage, or confluence with subdural hemorrhage.

This presentation will impact the forensic science community by demonstrating direct traumatic origin of optic nerve sheath hemorrhage without concomitant findings proposed by part of the forensic community as a prerequisite to the generation of such hemorrhage.

This presentation is based on a case study that provides essentially an experiment of nature. A 2-month-old infant was found unresponsive at his residence while under the sole care of his father. Death was pronounced at the scene without significant resuscitative efforts.

The infant presented postmortem without brain swelling and with soft fontanelles, but had optic nerve sheath hemorrhages and retinal hemorrhages as part of the anatomic findings. The calvarial plates were without fracture while dorsal calvarial sutures had soft tissue hemorrhage following the suture lines. There was right parietal subdural hematoma but no subdural hemorrhage contiguous with the optic nerves. There was subarachnoid blood staining but not in the proximal intracranial optic nerve sheaths. There was subdural blood about the cervical spinal cord but the neck on posterior dissection was without fracture.

An interview of the child's immediate caretaker first resulted in denial of knowledge about the origin of injury. Later, the caretaker admitted to an accidental drop of the child from shoulder height to the floor with intermediate impact of the child's head on a kitchen countertop two days prior to demise. The child was then less active than usual until found unresponsive on the day of death. The caretaker consented to further interrogation, including polygraph. He appeared truthful except upon questioning about shaking the child. When presented with the polygraphic findings, he then admitted to and described shaking the child vigorously when, after the fall, the child appeared in distress and he wanted to alleviate the symptoms to avoid discovery of injuries possibly incurred at the time of the fall.

This case does not solve the debate about impact versus shaking as the source of optic nerve sheath hemorrhages and retinal hemorrhages nor does it solve the issue of working backward from injury presentation to etiology of injury. The case does demonstrate that the optic nerve and retinal findings long considered associated with abusive child injury can, in fact, be the direct consequence of trauma. The finding of optic nerve sheath hemorrhage is not necessarily a secondary phenomenon related to resuscitation or the secondary effects of elevated intracranial pressure, but may be a primary finding.

Optic, Nerve, Hemorrhage

H49 Case Report: *Institutional Experience With the Molecular Autopsy and Its Obstacles*

Lorraine Lopez Morell, MD*, Wake Forest Baptist Hospital, Dept of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157; and Jerri McLemore, MD, Wake Forest School of Medicine, Dept of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157

After attending this presentation, attendees will better understand the ideal work-up in sudden unexplained toddler and young child deaths. Attendees will be more aware of the financial obstacles in place in the United States.

This presentation will impact the forensic science community by increasing awareness and opening a discussion about needed genetic testing in cases of sudden toddler and young child death.

According to the Center for Disease Control and Prevention Wonder database, sudden unexplained toddler and young child deaths, one to four and five to nine years old, respectively, account for 0.9/100,000 deaths per year (2011).¹ Like unexplained infant deaths, the cause for sudden unexplained toddler deaths can be elusive with no anatomic findings to explain the demise. "In fact, even after gross and histologic examination, at least 3% and perhaps as much as 53% of sudden deaths involving previously healthy children, adolescents, and young adults have no identifiable morphological abnormalities found at autopsy, remain unexplained, and are classified as autopsy-negative Sudden Unexplained Death (SUD)."² In cases of sudden toddler/child death, the ideal postmortem work-up would be similar to unexplained infant deaths and include a radiologic skeletal survey, bacterial and viral tissue cultures for microbiology, a full autopsy with detailed histological examination, review of medical and family history, and a thorough scene investigation. Because many cases have no findings whatsoever to explain the sudden death, blood and tissue samples should be retained for possible future studies, including genetic testing. The number of sudden unexplained toddler deaths in the United States due to genetic abnormalities is largely unknown. In general, medical examiners/coroners across the United States do not have easy access to molecular genetic testing due to financial constraints. The cost per positive diagnosis for long-QT syndrome alone can run up to \$45,000.³ As a result, opportunity to provide a definitive cause of death to the family is lost, as well as any chance of protecting other potentially at-risk individuals. As the molecular age of medicine advances, forensic pathology in the United States is slowly being left in the proverbial dust.

Within a few months' span, the Wake Forest Baptist Health (WFBH) department of pathology autopsy service autopsied two toddlers, ages two and four years of age, who had unexpected cardiopulmonary arrest and who were resuscitated and briefly placed on extracorporeal membrane oxygenation before being pronounced. Both toddlers had siblings; one had a twin. Full autopsies were performed but showed no clear grossly or histologically apparent etiology for their death except for a suggestion of possible cardiac fibroelastosis in one case. These two deaths were referred to the Pediatric Collaborative Care group at WFBH whose staff is composed of pediatricians in all subspecialties, medical geneticists, and other specialties as warranted for assessment. Circumstances and autopsy findings in both cases suggested a possible underlying genetic cause. This presentation highlights the current difficulties in obtaining funds in a cash-strapped medical examiner/coroner and hospital system and the various possibilities that may mitigate this problem.

H50 In Ballistics, Interpretations of Postmortem Multi-Slice Computed Tomography Are Often Simple ... But Not Always

Dedouit Fabrice, MD, Hopital Rangueil, Service de Medecine Legale, 1av. J. Poulhes, TSA 50032, Toulouse Cedex 9 31059, FRANCE; Frederic Savall, Service de médecine légale, Hopital de Rangueil, 1 avenue Professeur Jean Poulhès, Toulouse Cedex 9 31059, FRANCE; Fatima-Zohra Mokrane, MD, 1 Avenue Professeur Jean Poulhès, 31059 Toulouse Cedex 9, Toulouse 31059, FRANCE; Marion Vergnault, Hôpital De Rangueil, 1 Avenue Du Professeur Jean Poulhès, Tsa 50032, Toulouse 31059, FRANCE; Hervé Rousseau, PhD, 1 Avenue Professeur Jean Poulhès, Toulouse 31059, FRANCE; Daniel Rouge, MD, Service de Medecine Legale, Centre Hospitalier Univ Rangueil, Avenue du Professeur Jean Poulhes, Toulouse Cedex 4 31403, FRANCE; and Norbert Telmon, PhD, MD, Service Medico-Judiciare, CHU Rangueil, 1 Avenue Jean Poulhes, Toulouse F-31054, FRANCE*

After attending this presentation, attendees will understand that even if the number of Postmortem Multi-Slice Computed Tomography (PMMSCT) explorations in ballistic contexts is high, some radiological aspects may be difficult in terms of interpretation. This presentation presents and discusses different surprising postmortem multi-slice computed tomography explorations which are didactical for radiologists and forensic pathologists. This presentation insists on the quality needed concerning the police inquiries and on the fact that postmortem multi-slice computed tomography explorations are a precious complementary exploration for the forensic pathologist, which cannot be interpreted without autopsy or external examination elements.

This presentation will impact the forensic science community by showing three different surprising PMMSCT explorations that are difficult in terms of interpretation for radiologists and forensic pathologists. Seeing the abnormal aspects is one step; giving medicolegal sense and interpretation to this aspect, with an integration of the radiological aspects in one coherent and intelligent forensic meaning, is another step. This second step, in some particular situations, may surely be the most complicated and most problematic.

PMMSCT is now worldwide developed. One of the most frequent indications of PMMSCT concerns gunshot trauma; however, even if the number of PMMSCT in ballistic contexts is high, some radiological aspects may be difficult in terms of interpretation. This presentation will discuss three different aspects of PMMSCT which are didactical for radiologists and forensic pathologists.

Case 1: The first case concerns an 88-year-old man found dead on the ground, close to the base of a crane in a construction area. Based on the police investigations, the main hypothesis was a suicide from a fall from height. The PMMSCT showed presence of multiple subcutaneous and intra-cranial metallic pellets in the left fronto-temporal area. The detection of a bone defect was difficult due to metallic artifacts; however, some radiological aspects, like the absence of a clear cutaneous defect and absence of peri-lesional hemorrhage, did not suggest acute or recent gunshot trauma. The medicolegal autopsy confirmed the different radiological aspects. Furthermore, a slight cutaneous scar was noted at the left fronto-temporal region. Consequently, the hypothesis of a previous suicide attempt was retained. The final cause of the death was a poly traumatism secondary to a fall from great height. This case illustrates an unexpected detection of stigmata of previous gunshot trauma in a context of a fall.

Case 2: The second case concerns a 77-year-old man found dead in a lake with an anterior abdominal gunshot cutaneous entrance wound. Based on the police investigations, the main hypothesis was a suicide by gunshot. The PMMSCT revealed the presence of multiple hyperdense foreign bodies of different sizes within the chest. This aspect was interpreted as intrathoracic metallic pellets associated with two bullets. The medicolegal autopsy revealed that the two bullets were metallic elements of a button of the jacket worn by the deceased and displaced within the body during the gunshot due to the button's interposition between the end of the rifle and the skin. The final cause of the death determined by the forensic pathologists was a suicidal abdominal gunshot. This case illustrates the importance of the external examination and the autopsy elements because in this case, it was very easy to misdiagnose metallic fragments of a button as bullets. The association of different types of oriented projectiles resulted in initially opining the manner of death to be homicide. Consequently, false positivity concerning this aspect may have important judiciary consequences.

Case 3: The third case concerns a 73-year-old man found dead at home. Based on the police investigations, the main hypothesis was a homicide secondary to a multiple blunt trauma using a hammer. The PMMSCT revealed the presence of multiple subcutaneous and hyperdense foreign bodies located at the right fronto-temporal area. This aspect was interpreted as metallic pellets. The police investigation at the deceased's home led to the discovery of an airgun with a box of numerous small metallic projectiles. The medicolegal autopsy confirmed those findings except for the description of one projectile in the left orbit. This case illustrates the unexpected detection of some metallic air-gun bullets in a context of blunt trauma with a hammer.

Pathology/Biology Section - 2015

These cases illustrate that sometimes interpretations of the postmortem explorations performed in ballistic trauma may be difficult, revealing some unexpected or atypical aspects. It also underlines that the interpretation of the PMMSCT necessitates collaboration between radiologists and forensic pathologists.

Postmortem Imaging, Gunshot, Pitfall

Pathology/Biology Section - 2015

H51 Flash Fire Victims and Carboxyhemoglobin Concentrations: A Report of Ten Simultaneous Flash Fire Fatalities With Autopsy Findings

*Thomas K. Resk, MD**, 702 Mangrove Avenue, PMB 305, Chico, CA 95926-3948; *James A. Bailey, PhD*, Minnesota State University Mankato, 617 Chestnut Street, Wilmington, NC 28401; *Jeremy Stuelpnagel, MD, OCME*, New York City, 520 First Avenue, New York, NY 10016; and *Thomas A. Rudd, MS, MD*, Coroner of Lake County, Illinois, 26 N Martin Luther King Jr Avenue, Waukegan, IL 60085

After attending this presentation, attendees will understand the diversity of Carboxyhemoglobin (COHb) concentration findings in victims who die in flash fires. Further learning objectives include: (1) dealing with mass-casualty incidents in small, resource-challenged rural jurisdictions; and, (2) the effect of safety standards, both in the United States and internationally, which influence bus- and large truck-accident fatalities and injuries.

This presentation will impact the forensic science community by the presenting autopsy data on the ten people who died in a conflagration resulting from a collision of a motor coach bus vs. a tractor-trailer, big-rig truck at highway speed.

Motor vehicle collisions have been a leading cause of death and injury in the United States for decades. Injuries and deaths are typically caused by physical trauma, thermal injuries, toxic gases, or a combination of the three. Ten people died in a fiery conflagration on a late afternoon in perfect weather resulting from a collision between a motor coach bus filled with high school seniors and a big-rig tractor-trailer in Glenn County, CA. Travelling at highway speed, the tractor-trailer inexplicably crossed from the southbound lanes across an unfenced, flat median strip without protective vegetation into the northbound oncoming traffic lanes on Interstate 5, a major highway traffic corridor in the western United States. The drivers of both the truck and the bus died as well as eight bus passengers. The collision resulted in both traumatic injuries and thermal injuries from the ensuing flash fire which was suppressed within minutes by the local volunteer fire department. Complete autopsies were performed under the jurisdiction of the Glenn County sheriff-coroner on the nine victims who died at the scene. A tenth victim, who briefly survived, succumbed to his injuries hours later after having been flown to the University of California Davis Medical Center in Sacramento, CA. An external examination without complete autopsy was performed on that victim at the Sacramento County coroner's office. Of the nine autopsied victims, two died from severe traumatic injuries alone without elevation of COHb concentration, three died from inhalation of products of combustion without elevation of COHb concentration and with moderate traumatic injuries, two died from inhalation of products of combustion without elevation of COHb concentration and without significant traumatic injuries, and only two died with measurable concentrations of COHb – the first with 18% COHb concentration and traumatic injuries, the second with COHb concentration of 45% plus a Cyanide (CN) concentration of 4.17µg/ml and without traumatic injuries. The diversity of these autopsy findings within a cohort of victims dying together over a narrow time period support the fact that COHb concentration cannot be used as the sole criterion that a person was alive in a fire. Death in a flash fire results from the effects of a panoply of toxic compounds present in a flash fire including superheated gases.

Selected mass-casualty incident management issues arising in a small, rural county including triage, fire suppression, victim identification, body part identification, and disposition are examined.

This presentation will further discuss fire and crash-related issues which would diminish or mitigate flash-fire vehicular fatalities, including escapement, time to incapacitation, on-board fire suppression systems, fire detection, fire protection of vehicle passenger-occupied areas and fuel tank/engine areas, and the epidemiology of fatal bus crashes. Current national and potentially global safety standards for motor coach busses and large trucks are reviewed. Regulatory agencies have a responsibility to ensure that established safety standards are continually updated, seizing upon opportunities to improve accident survivability to minimize injuries and deaths from motor vehicle collisions.

Flash Fire, Bus Crash, Carboxyhemoglobin

H52 A Case of Intrauterine Fetal Cranial Injury After Attempted Suicide During Pregnancy

Lucia Tattoli, PhD, Sezione di Medicina Legale, Univerisity of Bari, Bari, ITALY; Giorgia Pinto, MD, University of Bari, Bari, ITALY; Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY; and Biagio Solarino, PhD, Università degli Studi di Bari, Sezione di Medicina Legale, P.zza Giulio Cesare, 11, Bari 70125, ITALY*

After attending this presentation, attendees will understand the importance of considering how relatively minor maternal trauma during pregnancy can lead to direct fetal injury *in utero*, especially during the second and third trimester.

This presentation will impact the forensic science community by showing the importance of manner-of-death reconstruction in unusual fetus injuries after maternal trauma.

Trauma in pregnancy is subdivided into three different types: blunt abdominal trauma; pelvic fractures; and, penetrating trauma. The effect of trauma on pregnancy depends on the gestational age of the fetus, the extent of disruption of normal uterine and/or fetal physiology, and type and severity of trauma. During the first trimester, minor trauma is not threatening to the pregnancy. During the second and third trimester, even relatively minor trauma can have significant adverse effects (e.g., maternal injury or death, shock, internal hemorrhage, intrauterine fetal demise, direct fetal injury, abruptio placenta, and uterine rupture). Blunt abdominal trauma associated with skull fractures and intracranial hemorrhage represents a rare event that complicates <1% of all pregnancies affected by trauma.

A case report of a 46-year-old woman who was 34 weeks pregnant when admitted to the Emergency Room (ER) after being found lying on the ground approximately 10 meters below an overpass. Witnesses noticed the woman driving fast along the overpass before being involved in a collision with the guardrail. Soon after the accident, she attempted suicide by jumping from the overpass guardrail. Police discovered the victim was concerned about her pregnancy and work.

She was admitted to the ER unconscious and obstetric/gynaecological personnel were consulted. Fetal heart tones were normal. A complete computed tomography scan showed fractures of five lumbar vertebrae, fractures of three ribs with pulmonary contusions, and a fracture of the left metatarsus with no cranial injury. After the mother was stabilized, the fetal heart tones were abnormal and, three hours after admission, the patient had an emergency caesarean section, delivering a male infant who was lifeless despite attempts at resuscitation.

No alcohol or drugs were found in the mother. After admitting to the suicide attempt, the mother was transferred to the psychiatric department where an unspecified episodic mood disorder was diagnosed. She recovered completely from the physical trauma.

Due to the unclear dynamics of the traumatic event, a medicolegal autopsy was performed on the baby. The external examination revealed a fully developed infant showing a deformity of the skull and left eyelid bruises. A massive subgaleal hemorrhage with a slippage of the left parietal bone below the right parietal bone was found. The brain showed a subarachnoid hemorrhage of the left temporal, parietal, and occipital lobes and of the right parietal and occipital lobes. Histological examination confirmed the brain injury and pulmonary signs of intubation. The cause of death was brain injury after maternal blunt abdominal trauma following a car accident and the fall from ten meters.

Direct fetal injury is significantly less common because the fetus is protected by the maternal body wall, uterus, and amniotic fluid. Fetal trauma usually occurs in late third trimester pregnancies when the amniotic fluid volume is low relative to the size of the fetus. Furthermore, the most common fetal trauma is head injury as the uterus is above the level of the pelvic rim and the head engages into the bony pelvis, possibly being compressed between the symphysis pubis and the sacral promontori.

The findings from this case confirmed that maternal “minor” trauma can be devastating for the fetus. Nevertheless, in any case of obstetric trauma, it is imperative to maintain the mother’s stability and survival since the survival of the fetus after a trauma depends on the mother’s condition with respect to oxygenation and hypovolemia.

Pregnancy, Blunt Abdominal Trauma, Fetal Trauma

Pathology/Biology Section - 2015

H53 **Skeletal Trauma Analysis in the Elderly: A Case Study on the Importance of a Contextual Approach**

*Ashley L. Humphries, MA**, University of South Florida, Dept of Anthropology, 4202 E Fowler Avenue, SOC 107, Tampa, FL 33620; *Ashley B. Maxwell, MA*, 18002 Allison Park Place, Apt 312, Tampa, FL 33647; *Ann H. Ross, PhD*, North Carolina State University, Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107; and *Jonathan Privette*, 3440 Reno Avenue, Charlotte, NC 28216

After attending this presentation, attendees will understand the advantages of using a contextual approach, as well as the value of forensic anthropological assessments, when interpreting patterns of trauma in potential elder abuse cases.

This presentation will impact the forensic science community by demonstrating the importance of considering age, medical history, and scene findings in interpreting the presence, timing, and cause of trauma by using a case study as an example. This presentation highlights the unique nature of the aging skeleton during forensic analyses. The elder skeleton presents different patterns of peri-mortem and postmortem trauma compared to younger adults, making interpretations of elder abuse difficult. In addition, this presentation will also underscore the importance of viewing all of the skeletal elements present, not just those in question.

With increasing age, the adult skeleton becomes weak and prone to fractures, especially in adults with osteoporosis, making injury interpretation difficult. Multiple studies have investigated common injury sites and mechanisms in elderly individuals; however, research concerning the timing of injury is lacking. Being able to distinguish accidental skeletal trauma from abuse-inflicted trauma, as well as postmortem damage, is significant in investigating possible cases of elder abuse and will impact criminal prosecutions.

In 2010, the mummified remains of a 93-year-old woman were found within her home in a sitting position on the couch, slumped over to her left side. She was completely clothed in winter clothing and covered by blankets, consistent with the season during which she died. The decedent's son failed to notify authorities of his mother's death and continued to cash her Social Security checks in the months following. Local authorities requested an autopsy due to the suspicious nature of the death and monetary gain by the son. During autopsy, peri-mortem fractures of the right ribs were observed by the medical examiner and a request was made for a forensic anthropological trauma analysis of the ribs. Initially, the medical examiner was only going to submit the ribs in question for trauma analysis. This could have resulted in an incorrect determination of the cause/manner of death. An incorrect conclusion of inflicted trauma could have resulted in inappropriate criminal charges.

Osteological examination revealed multiple bilateral antemortem rib fractures in different stages of healing as well as peri-mortem fractures. The decedent also displayed significant kyphosis and compression fractures throughout the vertebrae and advanced osteoporosis, as determined through radiographs of the proximal femur. In addition, she also had a left femoral head replacement consistent with common treatment for hip fractures in elderly individuals suffering from osteoporosis. A review of the decedent's medical history confirmed the diagnosis of osteoporosis and also revealed she had Chronic Obstructive Pulmonary Disease (COPD). COPD causes excessive coughing and, in someone with advanced osteoporosis, has been found to produce rib fractures.

Of particular concern in this case are the rib fractures. In juveniles, rib fractures in different stages of healing are consistent with abuse; however, with the decreased strength of bones in the elderly, their susceptibility to accidental injury, and decreased bone healing making existing fractures prone to re-fracture, the incidence of rib fractures in various stages of healing may not indicate abuse.

Along with the individual's medical history, examination of the scene photos was critical in making a final determination that the peri-mortem fractures observed on the left ribs were not due to inflicted trauma, but the result of the body weight exerting tension on the already fragile ribs. By taking into account aging factors, the scene, and existing medical conditions, the skeletal injuries were found not to be consistent with abuse.

Elder Abuse, Rib Fractures, Scene Evidence

Pathology/Biology Section - 2015

H54 Hydrogen Sulfide Fatality From a Domestic Sink Drain Exposure

Mary H. Dudley, MD*, Jackson County MEO, 660 E 24th Street, Kansas City, MO 64108; Marius Tarau, MD, 660 E 24th Street, Kansas City, MO 64108; Tom Hensley, 660 E 24th Street, Kansas City, MO 64108; Megha Garg, Saint Louis University, 20 N Grand Boulevard, St Louis, MO 63103; Diane C. Peterson, MD, Office of the Jackson Cty ME, 660 E 24th Street, Kansas City, MO 64108; Uttam Garg, PhD, Dept of Pathology, 2401 Gillham Road, Kansas City, MO 64108; and B. Robert Pietak, MD, 660 E 24th Street, Kansas City, MO 64108

After attending this presentation, attendees will be aware of the potential lethal effects of sewer gas in the home setting. Attendees will learn of the potential hazards of hydrogen sulfide exposure, autopsy findings, and toxicology sampling and results.

This presentation will impact the forensic science community by stressing the importance of scene investigation, autopsy findings, and toxicology results in order to determine the cause of death in hydrogen sulfide exposure from sewer gas in a home death.

Often referred to as “pit gas” or sewer gas, hydrogen sulfide is a highly toxic gas. It is naturally produced by decaying organic material in the absence of oxygen and is a byproduct of many industrial processes. Its toxicity most often occurs in occupational settings such as petroleum refineries, commercial fishing holds, and pools of sewage sludge or liquid manure. Fatalities often involve exposure to high concentrations of hydrogen sulfide (>150ppm).

Hydrogen sulfide concentration as low as 0.03ppm can be easily detected by its characteristic rotten egg odor. Respiratory tract irritations occur between 50-100ppm. Olfactory nerve paralysis, causing a loss of ability to smell the characteristic odor, occurs between 100-150ppm. Pulmonary edema occurs within 300-500ppm; levels of 600-800ppm are promptly fatal.

Clinical presentation of hydrogen sulfide toxicity includes headache, nausea, and vomiting. High-dose exposure may result in unconsciousness, seizure, and coma. Massive exposure can cause cardiovascular and respiratory failure leading to death. Diagnosis of hydrogen sulfide poisoning is generally made on the basis of history and clinical presentation. Laboratory diagnosis is helpful and is made through measurement of sulfide, thiosulfate, and sulfhemoglobin concentrations.

A 44-year-old White female with a past history of asthma was attempting to unclog a drain under a kitchen sink in her residence. She was discovered by her roommate unconscious on the kitchen floor with her head inside the cabinet under the sink. The drain pipes and drain trap had been removed by the subject and a solution known as “Liquid Fire” had been poured in the drain. Her roommate called 911 and the police and fire department arrived at the scene. The responding officer described the horrific sewer gas smell coming from the house. The subject was immediately transported to a local hospital where she was pronounced deceased.

An autopsy revealed a dusky gray-green discoloration to the gray matter of the cerebral hemispheres due to sulfur compounds. Histologically, the cortical neurons exhibited focal early hypoxic changes. The lungs exhibited moderate pulmonary edema and focal bronchioles with mucus plugs consistent with a history of asthma.

Toxicological analyses in hydrogen sulfide poisonings include measurement of sulfide and thiosulfate in various body fluids and tissues. Thiosulfate, in urine, is considered better than sulfide in the detection of sulfide exposure. Thiosulfate concentrations reported in fatalities range from 2.8-72.6mcg/mL. Sulfhemoglobin is another marker for hydrogen sulfide exposure. In unexposed subjects, the concentration of sulfhemoglobin is <1% in blood. In this case, the urine thiosulfate concentration was 15.5mcg/mL and the blood sulfhemoglobin concentration was 6.3%. The drug screen was positive for cannabinoids and methamphetamine (378mg/mL).

Based on the circumstances surrounding the death and the findings at autopsy, the subject of this case report died as a result of hydrogen sulfide intoxication with methamphetamine abuse and asthma as contributing factors. The manner of death was accidental.

Pathology, Sewer Gas, Hydrogen Sulfide

Pathology/Biology Section - 2015

H55 A Complex Bullet Path: Entrance in the Head, Exit Through a Body Orifice, and Re-Entrance in the Arm

*Vadim Mesli, MD**, Institut Medico Legal, Rue Andre Verhaeghe, CHRU Lille, Lille Cedex, Nord 59037, FRANCE; *Tournel Gilles, MD, PhD, IML de Lille, Faculté de Médecine, 1, place de Verdun, LILLE, FRANCE*; *Philippe Morbidelli, MD, Institut Medico Legal, Rue Andre Verhaeghe, CHRU Lille, Lille 59037*; *Erwan Le Garff, MD, Institut Médico-légal/Forensic Institute, Rue André Verhaeghe, Lille Cedex, Nord 59037, FRANCE*; *Yann Delannoy, MD, Forensic Taphonomy Unit, Rue André Verhaeghe, Lille 59000, FRANCE*; and *Valéry C. Hedouin, MD, PhD, Iml-chu Lille, Rue Andre Verhaeghe, Lille 59000, FRANCE*

After attending this presentation, attendees will have a better appreciation of unusual bullet paths in forensic practice, illustrated by a re-entrance wound in the arm, coming from a shot in the head which then exited through a natural body orifice.

This presentation will impact the forensic science community by providing an original example of a complex suicide following a homicide, with multiple gunshot wounds in the head, a re-entrance wound in the arm, and no visible exit wound.

Homicide-suicide is a particular form of interpersonal violence; it refers to the act of homicide followed by suicide of the perpetrator. Homicides followed by suicide patterns differ from both homicides and suicides internationally. In France, a homicide-suicide does not frequently result in a charge or trial. In this case, the findings at the crime scene initially led to a double-homicide suspicion due to the presence of multiple gunshot wounds.

A 58-year-old man, his wife, and their dog were found dead at home. He was lying on his bed in a supine position with three gunshot entrance wounds, one on the forehead, one next to the left temporal point, and one in the right arm. An unregistered .22 LR handgun (next to the bed, on his right side) and multiple fresh bloodstains were found in the bedroom. The wife was lying in a semi-supine position on the floor of their living room in a fresh pool of blood with a gunshot entrance wound on the vertex and no exit wound. No medical history was documented for either of them. Their dog also had a gunshot wound at the top of the head with no exit wound.

A radiological examination and autopsy of the man identified two bullets, one next to the C4 vertebra and one in the right arm. Three bullet trajectories were observed. The forehead wound had a close-range firing aspect, with soot depositions and a star-shaped laceration. The bullet's trajectory was through the frontal bone, the ethmoid, and the pharynx. The path from the left temporal entrance wound was through the frontal bone, the cribriform plate of the ethmoid, and the nasal septum. The second bullet was found in the subcutaneous area of the right arm. The three cutaneous wounds were confirmed as gunshot entrance wounds by a pathologist's examination. No other bullet was found at the crime scene or in the corpse. The entrance wound in the left arm was considered to be a re-entrance wound coming from the left temporal trajectory through a natural body orifice: the nostril. In this hypothesis, the decedent would have had his right arm wrapped around his face while he was shooting himself with his left hand. The toxicological analysis for all of the standard samples was negative. After complete investigation, the manner of death was classified as suicide for the man and homicide for the woman.

This case shows the importance of an open mind during the interpretation of bullet wounds paths, especially in complex cases such as this one. Multiple entrance wounds in the head and other locations might be self-inflicted, even if they appear to be suspected homicide.

H56 Autoerotic Accidental Death by Self-Inflicted Asphyxia by Body-Wrapping in a Plastic Curtain

Claudia Rosa, MD, S.C. Medicina Legale, ASL TO2, via Pacchiotti 4, Torino 10146, ITALY; Roberto Testi, MD, PhD, Via Lessona 54/12, Torino 10145, ITALY; Patrizia Mazzucco, MD, S.C. Medicina Legale, ASL TO1, via San Secondo 29 bis, Torino 10128, ITALY; and Paola A. Magni, PhD, University of Western Australia, Centre for Forensic Science, Myers St Bldg, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA*

After attending this presentation, attendees will understand an atypical method of autoerotic death by self-infliction due to body-wrapping in a plastic curtain.

This presentation will impact the forensic science community by providing data concerning an atypical method of self-inflicted asphyxia and the multidisciplinary approach to identify the causes and time-of-death.

Autoerotic accidental deaths are deaths occurring during solitary sexual rituals used to enhance sexual excitement. The majority of these fatalities involve the use of some type of apparatus that can enhance the sexual stimulation of the person, causing unintentional death. Hanging or self-inflicted suffocation are the most common forms of autoerotic accidental death.

In many cases, the diagnosis of autoerotic accidental deaths has been controversial and some cases have been classified as suicides with unusual features, rather than life-threatening accidents caused by sexual practices. The vast majority of autoerotic deaths are due to autoerotic asphyxia by hanging or by plastic bags (70% to 80%) and/or chemical substances (10% to 30%), but in approximately 5% to 10% of cases, atypical methods of autoerotic deaths are encountered (e.g., electrocution, overdressing/body-wrapping, foreign body insertion, and atypical methods of asphyxia).

In the present case, a 39-year-old man was found dead in his own apartment during the month of June, 2014, in Turin in northwest Italy. The door of the apartment was locked from the inside and no signs of forced entry were observed. The corpse was found on a bed, completely wrapped in a plastic curtain (typically used for showers). Both ends of the curtain were tied together, one end from the outside and the other end from the inside where the head was located. The curtain was laterally heat-sealed together using a hair straightener that was found on the floor close to a large number of empty beer bottles.

The body inside the sealed plastic curtain was found naked and in a supine position with the arms raised above the head. A plastic wrap was repeatedly rolled around his abdomen and three pieces of adhesive tape were tied to his penis. The body was highly decayed with body fluids spread over the bed and on the floor. Associated with this decomposition were blow fly (*Calliphora vicina* Robineau-Desvoidy, Diptera: Calliphoridae) larvae and pupae both inside and outside the sealed plastic curtain.

The death was considered as an autoerotic accidental death by self-inflicted asphyxia and not a suicide, even though it was determined that the subject was suffering some depression after he lost his job. In the context of this situation, the minimum time since death was established using the insects found on the body and in the surrounding area.

Asphyxia, Autoerotic, Body-Wrapping

H57 The Utility of CT Imaging in Determining Cause of Death in a Case of Iatrogenic Barotrauma

*Maggie Bellis**, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; *Michael J. Pickup, MD*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and *Michael S. Pollanen, MD*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA

After attending this presentation, attendees will understand how postmortem Computed Tomography (CT) imaging: (1) can be used in detecting air within the body cavities, tissues, and vessels; (2) can add valuable pre-dissection information; and, (3) is useful in guiding postmortem dissection.

This presentation will impact the forensic science community by bringing to light the value of CT imaging as an adjunct to postmortem examination and by bringing attention to certain postmortem cases which would benefit from having pre-autopsy imaging.

Advanced postmortem imaging is increasingly being utilized in the field of forensic pathology with many centers worldwide currently incorporating Postmortem Computed Tomography (PMCT) into their daily practice. One of the myriad advantages of PMCT imaging is its ability to detect air in body cavities, tissues, organs, and blood vessels which can be challenging to appreciate during routine dissection. CT scan provides nearly 100% sensitivity and specificity for the diagnosis of pneumothorax. Tension pneumothorax and other iatrogenic barotraumas such as air emboli and subcutaneous emphysema are known complications of mechanical ventilation. A case of iatrogenic barotraumas is reported, demonstrating the advantages of PMCT imaging in assisting with determining the cause and mechanism of death.

A 21-year-old man with Duchenne Muscular Dystrophy (DMD) was admitted to the hospital and treated for pneumonia. His pneumonia progressed to respiratory failure and, after several unsuccessful attempts at intubation, he lost vital signs. A postmortem examination was conducted to determine the cause of death. Prior to the autopsy, a full body CT scan was performed which revealed a large right-sided tension pneumothorax with left mediastinal shift, a completely collapsed right lung, subcutaneous emphysema, and air emboli within the heart and cerebral vasculature. At autopsy, the body was that of a young adult male with obvious atrophy of the upper and lower limbs. The imaging findings allowed for modification of the postmortem dissection technique in order to demonstrate air within the body cavities. A needle thoracostomy expressed a large volume of air from the right pleural space. The lungs showed bilateral collapse with acute bronchopneumonia and the heart showed DMD-associated cardiomyopathy histologically.

Barotrauma is an uncommon but well-recognized complication of mechanical ventilation; when it occurs, the mortality rate can be significantly high. This case highlights some of the advantages of PMCT as an adjunct to dissection, particularly for visualization and documentation of suspected barotrauma. In conjunction with dissection, PMCT added valuable pre-dissection information and assisted with the completion of a thorough, reviewable forensic autopsy. The advantages of PMCT in detecting air can be applied to several other case types including some SCUBA-related fatalities and sharp force injuries to the chest and neck.

CT Imaging, Postmortem, Barotrauma

H58 Fatal Pedestrian-Vehicle Encounters: Is Pedestrian Blood-Alcohol Concentration a Significant Factor?

Rodrigo N. Taniguchi*, Faculdade de Medicina da Universidade de São Paulo, Av: Dr. Arnaldo, 455 - IOF, Sao Paulo 04051000, BRAZIL; Carmen Silvia M. Miziara, MD, PhD, Rua Capote Valente, 127/111, Sao Paulo 05409000, BRAZIL; Ivan D. Miziara, MD, PhD, Rua Teodoro Sampaio, 352-22, Sao Paulo 05406000, BRAZIL; Julio Ponce, Av. Dr. Arnaldo, 455 -IOF, São Paulo, AB, BRAZIL; and Daniel R. Muñoz, MD, PhD, Rua Teodoro Sampaio, 155, São Paulo 05406000, BRAZIL

After attending this presentation, attendees will better understand the importance of measuring the Blood Alcohol Concentration (BAC) in forensic autopsy settings of fatal pedestrian-vehicle encounters, according to a one-year study from a group in São Paulo, Brazil.

This presentation will impact the forensic science community by providing scientific evidence to justify and recommend a simple procedure broadly available within forensic institutes that may have considerable medicolegal implications, especially to the driver of the vehicle involved in the incident.

Introduction: External causes of injury are the third-leading cause of death in Brazil and fourth in São Paulo State. Among these, traffic accidents are the second in prevalence in the country and the leading cause in the state.¹ Nearly one-third of all traffic accident deaths involve pedestrians.² In Brazilian society, strict laws prohibit drivers from having any blood alcohol levels whatsoever; however, the BAC of a pedestrian who is struck is of no concern.³

Objective: The goal of this study was to analyze the prevalence of alcohol intoxication in fatalities that involve a pedestrian struck by a motor vehicle according to official data.

Methods: This transversal study collected data from 2005 from the Instituto Médico Legal do Estado de São Paulo and the Companhia de Engenharia de Tráfego de São Paulo concerning pedestrian deaths. The variables of interest were age, sex, time of accident, cause of death, and blood alcohol level. Measures of dispersion and variability were used to analyze the data obtained.

Results: Four hundred five deaths occurred as a result of persons being run over by vehicles in 2005 in São Paulo city. Pedestrians were between 4 and 93 years of age with a median age of 48 years; the standard deviation was 19.3 years and the variability coefficient was 40%. The relationship between the age and the number of deaths represented a normal distribution with highest incidence between 45 and 50 years of age. In 69% of the cases, men were involved and in 27.5% of the cases, the victims were elderly people (≥ 60 years old). The most frequent causes of death were multiple trauma and traumatic brain injury, each responsible for 35% of the deaths. Half of all cases involved people between 35 and 60 years of age with 42.9% having alcohol in their blood. Of the elderly people, 14.5% had alcohol in their blood. When considering the cases between 40 and 50 years of age, most (52%) had some level of alcohol in their blood. In the 10- to 20-year-old group, 13% had alcohol in their blood.

Discussion: The high rates of BAC observed in this study characterize a public health issue. Alcohol consumption may have directly reduced the ability of the pedestrian to visualize, comprehend, and respond to risks. While many studies have emphasized the role of alcohol consumption regarding the driver, most of them fail to shed light on how pedestrians could also play a role or help to avoid these mishaps. This study recognized an active role of the pedestrian in a substantial portion of fatal vehicle-pedestrian encounters, which is important from two different perspectives. First, it emphasizes the importance of collecting samples for BAC measurement in the forensic setting for pedestrians struck by a vehicle. Second, it underlines the need for educational policies specific for drinking in pedestrian population of all ages.

Conclusion: A significant portion (35%) of the people who were run over had some level of alcohol in their blood; this rate was even higher in the 35- to 60-year-old population (42.3%). It is not possible, therefore, to rule out alcohol use of the pedestrian, which will have medicolegal implications in a possible judgment. Coroners should suspect alcohol abuse and request BAC measurement in all ages so their report can support an equitable judgment. Public health policies focusing on the alcohol-consuming pedestrian population are needed.

H59 When Life Makes No Sense — Suicide by More Than 150 Stab and Incised Wounds With Atypical Features

*Aniello Maiese**, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Lorenzo Gitto*, MD, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Serenella Serinelli*, MD, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena 336, Rome, Lazio 00169, ITALY; *Massimiliano dell'Aquila*, MD, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; and *Giorgio Bolino*, MBBS, Viale Regina Elena, 336, Rome 00169, ITALY

After attending this presentation, attendees will understand the difficulties in distinguishing between homicide and suicide when atypical sharp-force fatalities occur.

This presentation will impact the forensic science community by demonstrating the relevance of a concrete methodological approach when the circumstances surrounding death are not clear. In these cases, a complete crime scene investigation should be always performed, followed by an autopsy examination and laboratory analyses.

Deaths due to sharp force injuries are less common than other mechanisms of violent death. The most common manner of death associated with sharp force trauma is homicide, followed by suicide, while accidental fatalities are relatively rare. When a sharp force fatality with atypical features occurs, identifying the correct manner of death can be challenging for the forensic pathologists. At the crime scene, a large amount of blood is usually found due to the extensive blood loss from the skin injuries. Several features to distinguish between homicide and suicide are described in literature. The absence of the weapon, the presence of defensive wounds, and normally worn clothes are suggestive of homicide. The weapon at the crime scene and near the body, hesitation marks, and undressing are commonly related to suicide. Sometimes, it is possible for homicidal cases to have injuries that are indistinguishable from hesitation marks.

A case of atypical sharp force suicidal death is presented. A 32-year-old White male was found unresponsive in the living room of his flat, in a supine position. A pool of blood surrounded the body, showing no signs of sliding or splashing. The postmortem changes were consistent with a time of death of approximately six hours before the discovery of the corpse. Clothes were worn only on the lower limbs. On the body surfaces, multiple, widespread sharp force injuries were observed. Near the right hand, a kitchen knife was present. During the examination of the house, multiple bottles of psychoactive drugs were found. According to the declaration of the victim's parents, he had a history of bipolar disorder but no previous attempts of suicide were reported. No suicide note was found.

More than 150 injuries, widespread stab and incised wounds, were present, involving different body regions. Most of the wounds were incised wounds. On the back, more than 20 incised wounds were present, even on the back of the neck. At the internal examination, the six deepest wounds that penetrated the body were identified. On the right supraclavicular region, one lesion went deep inside the soft tissue of the neck and involved the external jugular vein. Upon a layered *in situ* dissection of the anterior neck structures, a hemorrhage in the soft tissue surrounding the affected vessel was observed. On the left hemithorax, one lesion penetrated the thoracic cavity and perforated a rib, but no injuries to the internal organs were present. On the abdomen, four lesions penetrated the abdominal cavity and two of these injured the small intestine and the right common iliac artery. Toxicological analyses were negative for alcohol, medical drugs, and drugs of abuse. A 3D reconstruction of the dynamic was performed using the 3D rendering software Poser Debut® on a MacOSX® computer.

Despite the scene circumstances and several aspects that were consistent with a suicidal death, the presented case combined several atypical aspects: the number of injuries — the total number was more than 150 considering cases of repeated incised wounds to the skin; the site of some wounds was not common (e.g., lesions observed on the back of the neck and the torso); there was a perforation of one rib by the knife; the toxicological analyses were negative, suggesting that the victim was in a state of manic psychosis characterized by dysphoria and paranoia and was determined to kill himself, despite being able to feel pain from the self-inflicted injuries.

Suicides involving a large number of sharp force injuries have been described; however, when atypical features are present, distinguishing between homicide and suicide can be difficult. In such cases, the evaluation of all available data is necessary to find the correct manner of death.

H60 Burned Human Remains: The Importance of a Multidisciplinary Approach

*Martina Focardi**, Largo Brambilla 3, Florence 50134, ITALY; *Francesco Mari*, Istituto di Medicina Legale, D, Policlinico Careggi, Viale Mor, Firenze, ITALY; *Ugo Ricci*, MD, Azienda Ospedaliero-Universitaria "Careggi", Diagnostic Genetics Unit, Largo Brambilla 3, Firenze 50134, ITALY; *Viola Bartolini*, University of Florence, Largo Brambilla 3, Firenze 50134, ITALY; and *Vilma Pinchi*, PhD, via Della Resistenza 2A, 14, Murlo, Siena 53016, ITALY

After attending this presentation, attendees will understand the complexity and critical issues related to forensic activity in cases of charred remains and will learn how to proceed with these types of cases.

This presentation will impact the forensic science community by illustrating an effective methodological approach to forensic activity and the identification of charred corpses. The recovery of burned skeletal remains may in fact represent an interesting, but sometimes difficult, challenge for forensic evaluation, given the frequently serious damage of the bodies. In such cases, it is essential to ascertain if the victim was exposed to fire before or after death. The forensic pathologist is called upon to determine the cause and manner of death and to discern if it was a case of homicide, suicide, or an accident. Another forensic need arising in such circumstances, both for the discovery of isolated bodies and in mass disasters, is the identification of the bodies, which is required for judicial reasons as well as ethical or religious causes. By developing a case report, the problems and strengths of the forensic activities carried out will be identified, thus providing useful information for the solution of fire-related deaths.

In December 2013, a group of forensic experts (two pathologists, an odontologist, a geneticist, and a toxicologist) were appointed by a judge in Prato, Italy, to identify seven victims recovered after a textile factory fire and to establish the cause of death.

In four cases, the toxicological investigations revealed very high levels of carbon monoxide ranging between 88.05% and 95.77%. Two people died from cyanide intoxication (with concentrations between 5.17mcg/ml and 8.85mcg/ml). In one case, there was a synergistic effect of the two substances (carbon monoxide and cyanide). The autopsy showed indicators of exposure to fire before death, with no traumatic injuries that could suggest a different cause of death.

The identification proceeded in accordance with the International Criminal Police Organization (INTERPOL) Antemortem (AM) and Postmortem (PM) protocols; in every case, one of the primary identifiers was satisfied. Given the high resistance of teeth to high temperatures, odontological examinations provided relevant data and genetic investigations confirmed all identities. Secondary means of identification, including personal descriptions, medical findings and devices, body piercing, clothing, and jewelry also proved to be very useful in correlating possible identities.

The primary difficulties were encountered in gathering AM information, due both to the language barrier (most of the relatives spoke only Chinese) and especially due to the lack of medical and dental information about the victims. The AM phase therefore required careful investigation by the forensic experts to overcome these problems and obtain data to compare with the examination on the remains.

Another critical issue, often causing mistakes in the identification process and in dynamics reconstruction, was the designation of the remains during the different forensic and investigation phases (recovery of the bodies, arrival at the morgue, then at the Forensic Science Department in Florence, Italy).

The contribution of each expert in charge was essential in solving the forensic issues, showing the multidisciplinary and integrated approach in every step of the activity (from the site inspection to the final report) as key to the solution of fire-related deaths.

Charred Corpses, Identification, Multidisciplinary Approach

Pathology/Biology Section - 2015

H61 A Retrospective Study of Drowning Cases in Tarrant and Adjacent Counties From 2008 Through 2013

Marc Jones, BS, Texas College of Osteopathic Medicine, UNTHSC, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; David Stephen, DO, Tarrant County MEO, 200 Feliks Gwozdz Place, Fort Worth, TX 76104; Nizam Peerwani, MD, Tarrant County OCME, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919; and Ronald L. Singer, MS, Tarrant County MEO, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919*

After attending this presentation, attendees will gain an increased knowledge and awareness of the prevalence of drowning and the most common risk factors associated with its occurrence.

This presentation will impact the forensic science community by increasing awareness of the fact that drowning is an all-too-familiar event in society and in the majority of cases is preventable. As many as 8,000 cases are reported annually in the United States. Education and heightened awareness is crucial to stemming this deadly tide. As with most dangers, prevention and avoidance of risk factors are the most reliable strategies. This presentation attempts to identify the most glaring risk factors and thereby enhance education on drowning prevention.

Drowning as a cause of death is a substantial concern among many communities, coastal or otherwise. It ranks among the leading causes of mortality among all age groups, especially in the pediatric population. In the United States alone, drowning accounts for 6,000-8,000 deaths annually. Therefore, it is imperative to be aware of the most common risks and circumstances involved in drowning. In this study, data was collected from case files of drowning incidents that passed through a medical examiner's office over a six-year period in order to determine the following questions: What sub-populations are most at risk for drowning? Where do drowning incidents most commonly occur? What are the risk factors and circumstances that prevented the victims from being extricated from danger? The data (n=234) indicated a predominance of male victims. In addition, an analysis of victims by age interval revealed a bimodal distribution, with toddlers and collegiate-age individuals being the most susceptible. With regard to location, swimming pools and lakes were the most common scenes of drowning. Identification of the lakes was performed to determine the sites where drowning occurred most frequently. One lake, Lake Lewisville, accounted for just over 25% of all recorded lake drownings in the area. Similarly, swimming pools were categorized as being private or public, and in-ground or above-ground. An overwhelming majority of the pools were determined to be private (82%) and in-ground (68%). Swimming pools also accounted for two-thirds of all pediatric drowning events. In the same vein, sufficient adult supervision was lacking in 90% of all pediatric drowning cases and barriers to pool entry were inadequate in 72%. In adult drowning incidents, alcohol use was found to be the most frequent risk factor present. Lastly, the phenomenon of "dry" drowning, in which the airways and lungs remain essentially free of the drowning medium, was considered and a novel set of criteria was generated to classify such cases. Of drowning events, 8% were identified as "dry" drownings but this sampling of individuals did not exhibit any discernible pattern with regard to demographics or circumstances.

Overall, this study corroborates and expands upon present knowledge and understanding of the epidemiology of drowning. Recognition of the most susceptible victims as well as the most likely circumstances surrounding drowning is invaluable to the formulation of strategies and the distribution of education to prevent drowning in the future.

Drowning, Epidemiology, Forensic Pathology

H62 Hemorrhagic Death With Particular Postmortem Computed Tomography Findings Associated With Decompression Illness: A Case Report

Yui Igari, MD*, Forensic Medicine, Tohoku University, 2-1 Seiryomachi, Aoba-ku, Sendai, Miyagi 980-8575, JAPAN; Tomoya Ikeda, MD, Forensic Medicine, Tohoku University, 2-1 Seiryomachi, Aoba-ku, Sendai 980-8575, JAPAN; Tadashi Hosoya, MD, Forensic Medicine, Tohoku University, 2-1 Seiryomachi, Aoba-ku, Sendai 980-8575, JAPAN; Akihito Usui, MS, Tohoku University, 2-1 Seiryomachi, Aoba-ku, Sendai 980-8575, JAPAN; Yusuke Kawasumi, MD, PhD, Tohoku University, 2-1 Seiryomachi, Aoba-ku, Sendai 980-8575, JAPAN; and Masato Funayama, JAPAN

The goal of this presentation is to describe an unusual case of fatal intraperitoneal hemorrhage with Decompression Illness (DCI).

This presentation will impact the forensic science community by illustrating particular postmortem computed tomography findings associated with DCI.

DCI is characterized by a wide range of symptoms caused by decompression of the body and includes two syndromes: Arterial Gas Embolism (AGE) and Decompression Sickness (DCS). In AGE, alveolar gas (secondary to pulmonary barotrauma) or venous gas emboli (via a cardiac shunt or the pulmonary vessels) enters the arterial circulation. DCS is caused by *in situ* bubble formation from inert gas dissolved within body tissues. Clinical manifestations range from trivial to fatal.¹

This report describes a case involving a diver in his mid-fifties who was working at a depth of 5m below the sea surface. About ten minutes after he started working, there was an explosive sound, and he returned to the sea surface rapidly. He was conscious at that time, but said that he could not breathe and collapsed shortly thereafter. He was transferred to a hospital and underwent cardiopulmonary resuscitation, but he could not be resuscitated. A doctor in the emergency room identified air bubbles within the blood during blood sample collection.

Postmortem Computed Tomography (CT) revealed massive hemorrhagic ascites and a large amount of gas within the heart chambers and blood vessels of the brain, liver, and groin region. In particular, the heart appeared to be expanded with gas. A radiologist stated that all of the gas was not likely to have been produced by putrefaction.

An autopsy was performed approximately 18 hours after the patient's death. No antemortem injuries were apparent on the surface of his body. The autopsy revealed traumatic rupture of the mesentery and approximately 2,600ml of blood with soft blood clots in the abdominal cavity. Only 5ml of blood was present in the heart, and the liver and kidneys were ischemic. No postmortem putrefaction changes were visible. Visualization of gas bubbles within the circulating blood was impossible because too little blood remained within the blood vessels. No bubbles were present in the hemorrhagic ascites. The decedent weighed 77kg and such massive hemorrhage was undoubtedly fatal. Therefore, the autopsy report concluded that the cause of death was attributable to intraperitoneal hemorrhage caused by traumatic rupture of the mesentery.

The characteristic finding in this case was a large amount of gas in the cardiovascular system, which was detected on postmortem CT. According to the literature, AGE can occur after ascent from a depth as shallow as 1.0m to 1.5m, and the minimum diving depth after which venous gas emboli can form is 3.6m, whereas DCS is uncommon at depths of <10m.^{1,2} In the present case, some of the gas may have formed gradually after death and it was impossible to determine the extent to which the gas contributed to the patient's death. Therefore, it was concluded that the gas had formed secondary to DCI, but the influence of the gas on the patient's death was not clear.

Reports of DCI with such particular CT findings as described in this case are rare.

Pathology/Biology Section - 2015

H63 A Bizarre Way to Kill the Ex-Wife: Two Knives Buried in the Chest, Two Additional Knives, and a Screwdriver Implanted in the Thorax

Joao E.S. Pinheiro, MD*, Instituto Nac Medicina Legal e Ciências Forenses, Largo da Sé Nova, Coimbra 3000-213, PORTUGAL; Antonio Padilha, Inst. Nacional de Medicina Legal e Ciências Forens, Largo da Sé Nova, Coimbra 3000-213, PORTUGAL; Maria Moura, Largo da Sé Nova, 3000-213, Coimbra, PORTUGAL; and Samantha Wijerathna, No 111, Francis Road, Colombo 8, Sri Lanka, Jmo Office, N Colombo Teaching Hospital, Ragam, Colombo, SRI LANKA

After attending this presentation, attendees will better understand lesional pattern caused by a combination of sharp and blunt weapons used in domestic violence. This presentation also highlights the importance of a complete autopsy in order to accurately determine the cause and manner of death.

This presentation will impact the forensic science community by applying an *in situ*, step-by-step, dissection technique in order to preserve, observe, and evaluate penetrating injuries. Furthermore, emphasis is given to the fact that the internal examination often adds relevant and unexpected data, for example, to what was thought to be a clarified and undoubted homicide. This case should also alert the forensic science community to the different forms of domestic violence — sometimes brutal and bizarre and often unexpected.

The body of a 47-year-old woman, divorced and living with her son, was found inside their new house with multiple cuts and stab wounds. This was following one of her ex-husband's occasional visits, which was intended to assist her in house-hold work. Two knives and a screwdriver were found *in situ*, penetrating the front of the chest.

Due to the multiplicity of the injuries and the *in situ* position of the weapons, a different dissection technique was adopted in order to preserve and interpret each path, particularly the stab wounds. The neck incision was made in such a way that the original injuries were preserved and the internal examination of the thorax was performed while the weapons, visible externally, were still *in situ* for as long as possible.

During the autopsy, the external examination showed multiple injuries of different types (cut/stab wounds, blunt and sharp-blunt) in the neck and thorax which revealed extreme violence. The neck injuries were extensive and difficult to describe because of the massive destruction of superficial and deep anatomical structures. Internally, it was confirmed that the thorax was penetrated by the screwdriver and the two knife blades which were completely inside the thoracic cavity. Surprisingly, when the thorax was opened, there were two more knives inside, one with a serrated blade and a clean edge and one embedded in the left lung.

All the injuries were assessed, the paths of the blades were described, and a comparison between the injuries and the shapes of blades was made in order to determine how those injuries were inflicted.

This case highlights how a different approach to the autopsy technique would enhance the interpretation of injury patterns, especially when multiple weapons are used in combination. It is clear that, despite the importance of the information collected in the external examination, the opening of the corpse provided unexpected findings even regarding the number of weapons. It is interesting to note that even though multiple weapons were used in this case, none of them penetrated the heart and the cause of death was determined as hemorrhagic shock due to a combination of multiple sharp and blunt trauma.

Multiple Knives, Screwdriver and Knives In Situ, Stab and Sharp Blunt Injuries

H64 Homicide or Suicide? A Case Report of an Atypical Hanging

*Furio Martino Patete**, Viale degli Aviatori, 1 C/O Medicina Legale, Ospedale C.D'Avanzo, Foggia 71121, ITALY; *Lucia Lops, MD*, Viale degli Aviatori 1, C/O Medicina Legale, Ospedale C. D'Avanzo, Foggia 71121, ITALY; *Francesco Sessa, BS*, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; *Sara Vita, MD*, Viale degli Aviatori 1, Foggia 71100, ITALY; and *Margherita Neri, MD, PhD*, University of Foggia, Dept Forensic Pathology, Viale degli Aviatori 1, Foggia 71100, ITALY

After attending this presentation, attendees will understand the distinction between suicide and homicide in cases of hanging. This presentation describes a case of hanging in which the crime scene was previously tampered with by the victim with the intent to simulate an execution in order to collect life insurance compensation. Characteristics of injuries, circumstances (for example, the victim's psychiatric disorders), and data collected from a detailed investigation of the scene as well as a complete postmortem examination including a toxicological analysis generally represent the major diagnostic criteria to determine the correct diagnosis.

This presentation will impact the forensic science community by outlining a complete methodological approach to interpretations of the summary of evidence that can contribute to the correct differential diagnosis between hanging or execution. A complete crime scene investigation has to be followed by external examination as well as a complete autopsy with the histological study of skin specimens to determine the validity of hanging marks. Radiological investigations should be also performed.

Case Report: A 44-year-old man was found lifeless hanging from a rope wrapped around his neck and anchored on the balcony railing of his office. The forensic pathologist was alerted by the prosecuting officer and a detailed crime scene investigation was performed. The office was in clear state of disarray. There were four overturned chairs and many documents scattered on the floor simulating the scene of a violent crime. Despite all of this, a chair was found next to the railing on the balcony where the rope was anchored. No suicide note was found. Cadaveric temperature was 36°C, rigor mortis was absent, and non-fixed hypostasis was observed on face, upper thorax, and hands. There were no relevant marks of external injuries. Excoriations and purple discoloration were present along the entire course of the ligature mark of the neck. Sub-conjunctival hemorrhagic petechiae were also recorded. Police officers related that the man phoned his girlfriend and alerted her that he was meeting someone concerning some job-related trouble and that he was worried about his safety because of this appointment. The prosecutor expressly requested a complete autopsy to determine the cause and manner of death.

Two days later, a postmortem computed tomography scan was performed. It excluded bone and visceral injuries and no traces of violence on the corpse were detected. The autopsy was unremarkable except for a mild hemorrhagic infiltration of the left side of neck associated with mild muscle fiber rupture. Mild cerebral and pulmonary edema with white foam in the main bronchi were also described. Pulmonary edema, congestion, and focal compensatory emphysema were recorded at microscopic analysis. Toxicological analyses on blood and urine were unremarkable.

The microscopic observation of the skin specimens from hanging marks demonstrated intra-epidermal erythrocytes and musculature alteration as "Zenker's necrosis." In addition, immunohistochemical investigation of skin samples was performed utilizing antibodies anti-tryptase, IL15, and CD15 which confirmed the vitality of reactions of the ligature mark.

The crime scene findings (a chair next to the railing was found), the absence of any external injuries, and the presence of vitality reactions in the ligature mark resulted in the conclusion of a suicide mimicking a homicide as the manner of death. Hanging remains one of the most commonly used methods for suicide worldwide. It may pose difficult challenges to forensic pathologists and disguising a suicide as a homicide is uncommon. In this case, the crime scene was tampered with in order to stage the death as a homicide. The police investigations revealed that the man subscribed to a life insurance policy that was valid in case of homicide. Furthermore, after a detailed investigation, a receipt issued for the purchase of the rope was discovered at the home of the victim, confirming the hypothesis of suicide.

Hanging, Altered Crime Scene, Homicide

H65 Impact of Postmortem Computed Tomography on the Evaluation of Strangulation Deaths

*Lauren A. Decker**, MSC08-4640, 1 University of New Mexico, Albuquerque, NM 87131; *Gary M. Hatch, MD*, University of New Mexico, Rad-Path Ctr for Forensic Imaging, MSC 07 4040, 1101 Camino de Salud, NE, Albuquerque, NM 87102; *Sarah Lathrop, DVM, PhD*, Office of the Medical Investigator, 1 University of New Mexico, MSC 07 4040, Albuquerque, NM 87131; and *Kurt B. Nolte, MD*, Radio-Path Ctr for Forensic Imaging, Office of Medical Investigator, MSC07 4040, 1 University of NM, Albuquerque, NM 87131-0001

The goal of this presentation is to aid forensic pathologists in understanding the utility of using Postmortem Computed Tomography (PMCT) as an additional tool in the evaluation of strangulation victims. Increasing reliance on technology has costs. Attendees will develop an understanding of the added benefits and inherent weaknesses of PMCT for strangulation deaths so they can determine the instances in which the use of this modality is appropriate.

This presentation will impact the forensic science community by assisting forensic pathologists in determining the settings in which PMCT is beneficial for the analysis of strangulation deaths.

Purpose: The value of PMCT was evaluated to augment autopsy in the evaluation of strangulation fatalities. The use of advanced radiologic imaging modalities such as PMCT may enhance the ability to detect injuries which may not be seen at autopsy.

Methods: This study combined a meta-analysis of strangulation (ligature and manual) deaths from other institutions with a cohort of similar deaths from New Mexico. A PubMed® literature search identified 30 studies which described autopsy findings in 576 strangulation deaths (50% ligature, 30% manual, and 20% combined or other) and two studies which described autopsy and CT findings in six strangulation deaths (33% ligature, 67% manual). In addition, 13 strangulation deaths were identified that underwent both autopsy and PMCT (46% ligature, 38% manual, and 16% other). The cases with autopsy only were compared with the cases of autopsy + PMCT for the presence of laryngochoyoid fracture and soft tissue hemorrhage.

Results: Fractures were detected in 53% of autopsy-only cases and only 26% of autopsy + PMCT cases. The detection rates of hyoid bone and cricoid cartilage fractures in autopsy-only and autopsy + PMCT cases were not significantly different: 27% and 11% ($p=0.11$) and 11% and 11% ($p=0.93$), respectively; however, the two cricoid cartilage fractures identified in the autopsy + PMCT cohort were only detected via PMCT. PMCT identified all hyoid fractures seen at autopsy, 2/3 thyroid fractures seen at autopsy, and 6/6 hemorrhages also identified at autopsy. There was a significantly lower incidence of thyroid cartilage fractures in the autopsy + PMCT cohort (45%) when compared to the autopsy-only cohort (21%), with a p value of 0.04. There was no significant difference between detection rates of hemorrhage.

Conclusions: No significant differences were identified between the findings described in autopsy-only strangulation deaths compared to autopsy + PMCT strangulation deaths, with the exception of the lower incidence in thyroid cartilage fractures in the autopsy + PMCT cohort. It is likely that the distribution of injuries in the autopsy-only and autopsy + PMCT groups were unequal due to the small sample size of the autopsy + PMCT group. While the frequency of cricoid cartilage fractures were similar between the cohorts, the only two cricoid fractures detected in the autopsy + PMCT group were discovered by PMCT. PMCT may have a role in detecting these subtle fractures. Additionally, the results indicate that PMCT, in most cases, is equally able to detect injuries in strangulation deaths as autopsy and may be used in place of autopsy in certain settings such as cases of accidental or suicidal strangulations.

Strangulation, Postmortem Computed Tomography, Autopsy

H66 Cardiac Arrest During Police Restraint in a Man With Catecholaminergic Polymorphic Ventricular Tachycardia (CPVT): Frightened to Death?

*Ashwyn Rajagopalan, MD**, 25 Morton Shulman Avenue, Toronto, ON M5T 1V1, CANADA; and *Michael S. Pollanen, MD*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA

After attending this presentation, attendees will be able to better ascribe the cause of death in these controversial cases and will understand the role of the molecular autopsy in cases of sudden death.

This presentation will impact the forensic science community by highlighting the value of the molecular autopsy and by revealing how an evolving knowledge base can lead to reinterpretation of existing genetic data.

Instances of sudden and unexpected death while in police custody remain complex and controversial cases in forensic pathology, providing unique diagnostic challenges. In general, the circumstances of these cases have resulted in two major theories to account for these deaths: “excited delirium syndrome” and positional (restraint) asphyxia; however, some cases that are not easily explained by one of these theories may be best explained by a theory from another emergent area in forensic pathology, non-structural genetic heart disease. One such case, a sudden arrhythmic death during struggle/restraint, is presented.

A 45-year-old man with developmental delay was walking outdoors, when, in a tragic case of mistaken identity, he was identified as a suspect by police officers, who attempted to take him into custody. He resisted this arrest violently. He was taken to the ground and restrained in a face-down position, from which he moved his extremities and pushed his chest off the ground. He was subsequently observed to be cyanotic and non-responsive. He was placed into a recovery position and resuscitation attempts were started. Paramedics found him to be asystolic. He was transported to the hospital and pronounced dead. The interaction with police was too brief to account for an asphyxial death. There was no history of a delirious state.

At autopsy, there were minor external blunt force injuries and small hemorrhages within the neck, arms, and back. The heart showed mild cardiomegaly with concentric left ventricular hypertrophy and sub-occlusive atherosclerotic luminal stenosis. Toxicological testing was negative for common drugs, including cocaine and its metabolites. Postmortem molecular testing demonstrated this man to be heterozygous for a catecholaminergic polymorphic ventricular tachycardia (CPVT) associated mutation (Phe189Leu) in the Calsequestrin 2 (CASQ2) gene. This mutation was initially classified as class II mutation (unknown significance), which would be expected to cause disease in a heterozygous state. Subsequently, the mutation was reclassified as a class I mutation (deleterious) that may cause disease in a heterozygous state. The cause of death was cardiac arrhythmia precipitated by struggle/restraint in a man with CPVT. This case illustrates the difficulty assigning a scientific cause of death in rare and controversial cases, the value of the molecular autopsy in identifying disease causing mutations, and how an evolving knowledge base can lead to reinterpretation of genetic data.

CPVT, Police Restraint, Molecular Autopsy

H67 **Atypical Self-Strangulation Through a Sphygmomanometer: An Uncommon Suicide Method**

*Sara Lo Pinto, MD**, University of Genova, Via de Toni 12, Genova 16132, ITALY; *Tiziana Tacchella, MD*, University of Genova, Via de Toni 12, Genova 16132, ITALY; *Francesca Fossati, MD*, Via de Toni 12, Genova 16132, ITALY; *Alessandro Bonsignore, MD*, University of Genova, Dept of Legal & Forensic Med, Via de Toni 12, Genova 16132, ITALY; and *Francesco Ventura, MD*, via de Toni, 12, Genova 16132, ITALY

The goal of this presentation is to share the exceptional nature of the presented case which suggests taking sphygmomanometers into consideration as possible tools to perform self-strangulation. At the same time, it emphasizes the importance of the management of psychiatric patients and patient, whether psychiatric or not, with cognitive disorders; indeed, particular caution is required in order to keep them at a safe distance from objects that although apparently harmless, can become lethal.

This presentation will impact the forensic science community by presenting an unusual form of suicide performed by a young Italian man with a standard mercury sphygmomanometer, a manner of death previously not described in the reviewed literature.

A forensic approach by means of scene investigation, circumstantial data collection, autopsy, and toxicological investigation led to the conclusion that the cause of death was a mechanical asphyxia, ascribed to self-strangulation by an atypical item. The analysis of blood and urine excluded the presence of alcohol, amphetamine-methamphetamine, MDMA, barbiturates, THC, cocaine, opiates, methadone, and benzodiazepines.

Italy's National Institute of Statistics data for the period 1993-2009 suggest that hanging and other forms of asphyxia are the most common methods of suicide among men (52.1%), while for women asphyxia only represents the second cause of suicide (33.4%), with falls from height being the first (35.1%). Moreover, these official data also show that suicides most often occur in people over 45 years of age.

World Health Organization data confirms that suicide among young people is rare; however, in recent years, the trend has been increasing, especially in developing countries, with globalization-related changes in work practices and stress suggested as the possible causes of identity loss.

In the presented case, a 16-year-old male was discovered lifeless and seated on his bed by his mother (a nurse). The victim had suffered from Attention-Deficit/Hyperactivity Disorder Syndrome and was supported by personal teachers. He had a solitary and depressed character and had recently spent considerable time visiting satanic websites.

One day, after coming home from school while his parents were temporarily absent, he stole his mother's sphygmomanometer and strangled himself.

A thorough analysis of the literature reveals several cases of strangulation mainly related to accidents or homicides (e.g., deaths from life-threatening sexual practices; a peculiar case of a thief trapped between automatic sliding doors during a bungled attempt to enter a supermarket during the night; a victim of the well-known Isadora Duncan syndrome; strangulation by a scarf caught in the moving wheel spokes of a vehicle; choking by a rope passed around the victim's wrists, ankles, and throat (as a typical Mafia homicide); and so on). Other researchers describe uncommon suicidal strangulation methods (e.g., nylon rope around the neck and tied to the right ankle to prevent the rope from untying; a walking stick utilized with a tourniquet effect).

The use of a sphygmomanometer for this purpose is even rarer as it requires the repetition of the action to inflate the cuff around the neck with a progressive asphyxial mechanism and the onset of symptoms connected to this action.

Uncommon Suicide, Self-Strangulation, Sphygmomanometer

H68 The Importance of Postmortem Computed Tomography in a Gunshot Wound-Related Death: A Case Report

Giorgio Bolino, MBBS, Viale Regina Elena, 336, Rome 00169, ITALY; Lorenzo Gitto, MD, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; Massimiliano dell'Aquila, MD, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; Serenella Serinelli, MD, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena 336, Rome, Lazio 00169, ITALY; and Aniello Maiese*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY*

After attending this presentation, attendees will have a better understanding of the usefulness of Postmortem Computed Tomography (PMCT) in a gunshot wound-related death.

This presentation will impact the forensic science community by demonstrating the accuracy of PMCT in the depiction of the wound track, discerning between entrance and exit wounds, and showing the bone's fracture and the internal course of the bone fragments.

PMCT is especially useful in gunshot wound cases, allowing an easier location and retrieval of the bullet and/or its fragments inside the body that may help in identifying the ammunition and the weapon type utilized; however, PMCT permits a detailed preliminary 3D documentation of the ballistic effects, allowing one to obtain essential information such as: accurate depiction of the wound track; discerning between entrance and exit wounds; and, demonstrating a bone's fracture and its fragments' course inside the body. Of these, the study of the bullet course inside the body is of extreme importance for the reconstruction of the event and to understand the positions of perpetrator and victim, with special regard to homicide cases involving fatal gunshot wounds.

A case of gunshot wounds in which PMCT scans were performed is presented. The case concerns a 73-year-old White male found unresponsive in his truck. Multiple gunshot wounds were observed on his body, affecting the upper arms, the neck, and the head.

A preliminary PMCT scan was performed before the postmortem examination. The following features were described in the CT report on the soft tissues of oropharynx: just in front of C2 vertebral body, a foreign conical-shaped metallic body was present (2x1.3cm) referable to a bullet; on the mandibular body, a burst fracture and a dislocation of teeth were present; on the left mandibular branch, multiple fractures were present; on the right maxillary bone, a displaced fracture was present that led to a dislocation of the alveolar arch; on the atlas vertebra, a fracture of the right anterior arch and a fracture of the right lateral mass were present; a misalignment between the atlanto-epistropheal joint and the C3 vertebral body was present; and, at the external examination of the body, 18 gunshot wounds were observed. Despite the high number of gunshot wounds, only six bullets were fired, suggesting the presence of multiple re-entry wounds. At the postmortem examination, the wound paths were able to be clarified.

In this case, the PMCT found all the wound paths and their direction inside the body. In particular, five wound paths (of which 4 blind paths), were identified with multiple re-entry wounds. In all cases, the wound courses traveled left to right, front to back and upwards. This study found the PMCT extremely accurate in the localization of the bullet; however, due to the PMCT, the misalignment between the atlanto-epistropheal joint, difficult to visualize using the standard autopsy examination, was found.

According to these findings, the dynamics of the event were reconstructed. The subject was sitting in the cockpit of his truck, while the offender was standing at a distance of >50cm from the left door (driver's seat side). The offender started firing multiple times, aiming at the head of the victim. The victim tried to protect himself by performing a right-side rotation and putting his left arm, forearm, and hand to the face, like a shield. The suggested scenario justifies the large number of gunshot wound found on the body, despite only six shots being fired.

In conclusion, the reported case emphasizes the importance and the advantages of the PMCT in forensic science and ballistics. The multislice scans together with the 3D rendering allow easy localization of bullets and their fragments inside the body in order to identify and reconstruct the wound paths, with special regard to the injury to the soft tissues, the parenchymal organs, and the bones; however, this technique is of great help in the identification of injuries located in body regions which are difficult to locate by dissection, such as the posterior neck region, the soft tissues of the face, and the cranial bases. The biggest disadvantage of this technique is the inability to recover the bullet or its fragments from the body by use of this technique alone.

Virtopsy, Gunshot Injuries, 3D Reconstruction

Pathology/Biology Section - 2015

H69 Terminal Performance of Zombie-Killing Bullets and Polymer-Tipped Bullets

*Todd M. Luckasevic, DO**, Allegheny County ME, 1520 Penn Avenue, Pittsburgh, PA 15222; *David K. Arboe II, MD*, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222; *Thomas M. Morgan, BS*, Allegheny County MEO, 1520 Penn Avenue, Pittsburgh, PA 15222; *Kenneth H. Clark, MD, PhD*, Allegheny County ME, 1520 Penn Avenue, Pittsburgh, PA 15222; and *Abdulrezak M. Shakir, MD*, Allegheny County OME, 1520 Penn Avenue, Pittsburgh, PA 15222

The goal of this presentation is to illustrate the terminal effects of polymer-tipped handgun bullets on the human body and the counter-effects of the body on the tipped bullet.

This presentation will impact the forensic science community by illustrating the terminal ballistics/performance of polymer-tipped handgun bullets that were recovered during autopsy. This presentation will illustrate the need for awareness of tipped bullets and collaboration between the forensic pathologist and the firearm examiner when dealing with cases of polymer-tipped bullets.

Introduction: Polymer-tipped rifle bullets have been around since the mid-1980s. They were first developed by Nosler® to provide streamlined shape with the expansion of a hollow-point bullet. Polymer-tipped handgun bullets, which are a more recent invention developed in the mid-2000s, are being encountered more by forensic professionals.

Polymer-tipped handgun bullets are designed to expand reliably and not clog like standard hollow-point bullets when fired through heavy clothing. The polymer tip/insert is also designed to feed reliably in semi-automatic pistols. The bullets are advertised to deliver controlled expansion with large deep-wound cavities over a wide range of velocities.

Materials and Methods: The autopsy and scene pictures were reviewed for two individuals that were shot with Hornady® polymer-tipped bullets. The first individual was a 24-year-old male who weighed 215 pounds and measured 74.5 inches. He was shot twice with Hornady® Zombie-Max™ ammunition in the trunk. The second individual was a 27-year-old male who weighed 148 pounds and measured 68 inches. He was shot once in the chest with Hornady® Critical Defense® ammunition.

Results: A slightly deformed non-expanded 45 caliber Hornady® Zombie-Max™ bullet with a green polymer tip was recovered from the left thigh. The bullet entered the right lower back and injured the skin, subcutaneous tissues, and muscles of the right buttock. The bullet lacerated the urinary bladder and fractured the pubic ramus. A deformed and fully expanded 45-caliber Hornady® Zombie-Max™ bullet was recovered from the chest muscles. The bullet entered the left back and injured the skin, subcutaneous tissues, and muscles of the back. The bullet lacerated the left lung and heart and fractured the left 9th rib.

A slightly deformed, non-expanded 40-caliber Hornady® Critical Defense® bullet with a red polymer tip was recovered from the soft tissues of the anterior chest. The bullet entered the left lateral chest and injured the skin, subcutaneous tissues, and muscles of the chest. The bullet lacerated the heart and fractured the left 3rd and 5th ribs.

Conclusions: Two of the three Hornady® polymer-tipped bullets did not perform as advertised. The 40-caliber Hornady® Critical Defense® bullet passed through a thick hooded sweatshirt and two thin T-shirts before impacting and fracturing two ribs. The 45-caliber Hornady® Zombie-Max™ bullet passed through denim jeans and cotton boxers before impacting and fracturing the pubic ramus. The counter-effect of human bones on the bullets caused crimping of the bullet tip, thereby entrapping the polymer insert, resulting in minimal expansion of the bullets.

Ballistics, Polymer-Tipped Bullets, Zombie

Pathology/Biology Section - 2015

H70 Savage Murder: Mutilation and Dismemberment — Why, When, and Where?

Baiyang Xu, MD*, Allegheny County MEO, 1520 Penn Avenue, Pittsburgh, PA 15222

The goal of this presentation is to illustrate an unusual case of homicide with dismemberment and to highlight some of the challenges of investigating and examining such cases.

After attending this presentation, attendees will have a better appreciation for the difficulties in evaluating homicides with mutilating injuries, as well as offer insight into the possible racial motivations which underlie such gruesome crimes. Attendees will also gain a greater comprehension of how the examination/investigation can be confounded by the different environmental conditions in which body parts may be found, which may result in postmortem artifact and may obscure the lesions associated to the immediate cause of death.

Case Report: On February 14, 2011, the mother of a 23-year-old African American man reported her son missing after his co-worker called her, worried that her son had not shown up for work for two days, which was unusual. Initial investigation revealed that the son was last seen with a White female in a bar three days prior and left to go to her home later that night. An interview with this White female revealed that her half-brother, who resided with her, came home and found the man with her in bed. The half-brother physically removed the man from the bed and told her that he was going to take him home. The suspect's best friend informed police that the suspect contacted him later the following day and asked him come to his house to help him. Upon arrival at the home, the best friend learned that the suspect had killed a man and already dismembered the body and placed the body parts into two separate plastic bags. The best friend further related that he helped to dump the body at the bottom of a steep drop over a hillside away from the residence area, where the trunk and upper and lower limbs were taken out of the bags and buried. The head was thrown away randomly to an unknown location by the suspect. At the time of discovery of the body parts, the trunk and all four extremities were well preserved. The head was found 24 feet away from the rest of the body parts and showed a significant amount of animal activity. A total of six dismembered body parts were found: (1) head, decapitated at the 3rd and 4th cervical intervertebral disc; (2) trunk with attached proximal upper and lower extremities; (3, 4) distal segments of the upper limbs severed at the lower third of the humerus; and, (5, 6) distal segments of the lower limbs severed at the distal third of the femur. The skin and soft tissue margins of the body segments were somewhat regular. The bone sections of limbs showed coarse striations and break-away spurs indicating the dismemberment tool was a saw.

The autopsy also demonstrated that the decedent sustained at least 72 sharp force injuries. The incised wounds seen on both the right and left hands were most consistent with defensive-type injuries. The stab wounds in the neck transected the left common carotid artery and perforated the trachea with extensive hemorrhage in the adjacent soft tissues which, taken together, were considered as the antemortem lethal injuries leading to the death. The rest of the incised and/or stab wounds were distributed in a clustered fashion involving the head and neck, right upper back, and left upper and mid back with relatively less or no hemorrhage in the adjacent soft tissues. Postmortem toxicology studies show ethanol: 0.140% in bile and 0.219% in urine.

Police found the blood-stained seats from suspect's car, the decedent's clothing, and blood-stained gloves in the basement of suspect's mother's house. DNA testing matched these blood stains to the victim's and the DNA in the gloves matched those of the suspect.

Discussion: Dismemberment is a relatively rare method of body disposal. Criminal dismemberment, with regard to all legal autopsies, has an average frequency of 1:500. Most cases involve the "traditional" tools for severing the body apart, such as a saw, axe, or knife. The features of the margin sections of the soft tissues and bones indicate that the suspect cut the skin and soft tissue with a sharp knife, then separated the bones with a saw. In the literature, most dismemberment is performed at the site of homicide. In this case, the killing was in suspect's car and the dismemberment was performed at the suspect's mother's house. The postmortem artifacts or decomposition related to environmental exposure sometimes obscure the physical integrity of the injuries or, in some instances, make the pattern and severity of injuries impossible to determine. The victim's head in this case was separately thrown in an open, outdoor environment. The result of this was that the soft tissue of the left side of the face and the neck, including the skin, muscle, tongue, and hyoid bone, was partially consumed by animals. The entrance of the lethal stab wound on the anterior neck was not clearly present at the autopsy but careful dissection and examination of the wound path and adjacent tissues still allowed the examiner to make the right determination. The suspect subsequently confessed that he attacked the victim in his vehicle with a stab through victim's anterior neck. At that time, the victim was intoxicated with ethanol and defended himself, but inefficiently.

Dismemberment, Sharp Force Injury, Postmortem Artifact

H71 The New Italian Law on Femicide: Was There a Real Reduction of Cases of Femicide? The Foggia (Apulia, Italy) Scenario

Benedetta Di Battista, MD, Viale degli Aviatori, 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; Stefania C. Bello, MD, Ospedale Colonnello D'Avanzo, viale degli Aviatori, Foggia 71100, ITALY; Margherita Neri, MD, PhD, University of Foggia, Dept Forensic Pathology, Viale degli Aviatori 1, Foggia 71100, ITALY; Natascha Pascale, MD, Viale Degli Aviatori, Foggia 71100, ITALY; Cristoforo Pomara, MD, PhD, University of Foggia, Dept Forensic Path, University of Malta, Dept of Anatomy, Faculty of Med & Surg Biomedical Sci, Foggia, Misida, Malta 71100, ITALY; Stefano D'Errico, MD, University of Foggia, viale degli Aviatori, Foggia 71100, ITALY; Irene Riezzo, PhD, Univ of Foggia, Osp D'Avanzo, Dept of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71100, ITALY; Francesco Sessa, BS, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; and Emanuela Turillazzi, MD, PhD, viale degli Aviatori 1, Foggia 71100, ITALY*

After attending this presentation, attendees will better understand the evolution of the Italian scenario of femicide after the enactment of a new Italian law.

This presentation will impact the forensic science community by presenting information about the introduction of new Italian legislation and its effects on the reduction of cases of femicide, as reported by the Italian Ministry of the Interior; however, in Foggia, an increase of femicides was observed, resulting in many discordant opinions on the matter.

The word femicide is very recent. In 1992, Diana Russell, with the term “femicide,” defined it as extreme violence against a woman by a man because she is a woman, while in the 1990s, several terms were used to describe the murder of a woman that occurred within a relationship or cohabitation, including spousal homicide and family-related homicide. Statistics show that when a woman is killed, the perpetrator is often a man who has been intimately involved with her. A total of 2,412 femicides were recorded in Italy between 2000 and February 2014. Of these, 1,698 were committed inside the victim’s house or during relationships and 1,059 were committed by the husband, intimate partner, or ex-boyfriend. In 2013, a woman was murdered every three days in Italy and femicide represented 35.33% of all homicides. Due to the severity of this issue, in Italy a law was enacted in 2013 (Law n° 119, October 15th 2013). This law concerns new rules to fight gender-based violence in order to prevent femicide and protect victims, all within the framework outlined by the Convention of Istanbul (2011), the first legally binding international instrument on preventing and combating violence against women (defined as a violation of human rights and a form of discrimination against women and shall mean all acts of gender-based violence that could result in physical, sexual, psychological, or economic harm or suffering to women, including threats of such acts, coercion, or arbitrary deprivation of liberty, whether occurring in public or in private life) and domestic violence (violence that occurs within the family or domestic unit or between former or current spouses or partners, whether or not the perpetrator shares or has shared the same residence with the victim). According to the data of the central management of the Italian Criminal Police (State Police), in the first two months of 2014 compared to the same period in 2013, a decrease in cases of femicides was noted. In fact, in January/February 2013, femicides represented 29.41% of all homicides, compared with 22.4% of cases in January/February 2014; however, only the complete data of the year 2014 provide an insight into whether the law has achieved the desired results.

The goal of this study is to review the autopsy cases performed at the Department of Forensic Pathology, University of Foggia, Italy. Cases of femicide were selected and categorized according to the emotional relationship between the victim and the killer and on the basis of manner of death. The cases of femicide from 2001 to 2014 at the Department of Forensic Science of the University of Foggia were analyzed. An analysis of 1,281 autopsies performed in the department is presented with the goal of selecting which and how many of these were murders that had female victims, evaluating the mechanism of death, and the history of sentimental relationship between the victim and the offender. Of the 136 homicides in Foggia, 38 were femicides committed by the husband (18), intimate partner (15), ex-boyfriend (2), son (1), cousin (1), and uncle (1). Of the 38 femicides, 14 presented with blunt injuries, eight with stab wounds (1 with decapitation), 7 with gunshot wounds, 5 from asphyxial mechanism (1 with drowning after being linked to the hands and feet and sealed by scotch tape on the mouth, 2 by suffocation, 2 by strangulation), and 4 combined gunshot and blunt injuries.

Unfortunately, the data seems to confirm the doubts about the effectiveness of the law on femicide as they show an increase. In the case series, femicides represented 27.56% of all homicides before the enactment of the law and 40% of all homicides in the months after the law came into effect. In conclusion, the data continue to show a worrying increase in femicides.

H72 Lethal Drug Intoxication of a Bank Robber: The Role of Physical Restraint

Pasquale Beltempo, MD, D.I.M., Sezione di Medicina Legale, piazza Giulio Cesare, 11, Bari, Puglia 70124, ITALY; Roberto Gagliano-Candela, Cattedra Tossicologia Forense, Policlinico, Piazza G. Cesare 11, Bari 70124, ITALY; Valeria Bruno, MD, D.I.M., sezione di Medicina Legale, piazza Giulio Cesare, 11, Bari, Puglia 70124, ITALY; and Biagio Solarino, PhD, Università degli Studi di Bari, Sezione di Medicina Legale, P.zza Giulio Cesare, 11, Bari 70125, ITALY*

The goal of this presentation is to discuss controversies that often arise concerning deaths that occur under physical restraint, with disputes due to increasing public concern on the recourse of violence by police officers and to the byzantine definitions of self-defense among countries' legal frameworks.

This presentation will impact the forensic science community by stressing the prominent role of a thorough synopsis of the results from testimony, scene inspection, and a complete autopsy – with radiological and toxicological analysis – when dealing with deaths that occur during physical restraint.

Choke holds, also known as “*shime waza*” in the sport of judo, are widely used by police officers to subdue violent suspects. It was once believed to be a safe and harmless way of controlling and subduing violent suspects; however, recently, multiple case reports and reviews have emphasized the possible lethal effect of neck compression during physical restraint.

Conversely, cocaine is a major cause (36%) among undetermined deaths occurring during physical restraint or custody. Cocaine is a powerful sympathomimetic agent; its role in the sympathetic sensitization of the myocardium has been widely discussed. Cocaine increases myocardial inotropy, heart rate, and blood pressure in a dose-dependent manner, thus increasing myocardial oxygen demand.

Some case series report deaths that occurred during choke holds on subjects whose blood samples were positive for cocaine; however, in these reports, cocaine blood levels are not quantified.

A case of an attempted bank robbery is presented. The perpetrator came into the bank wearing a baseball cap and sunglasses holding an electronic device, claiming it was a bomb. One of the bank clerks and a customer immediately realized that the electronic device was a power transformer and attempted to push the robber outside the bank. During the struggle, the robber pulled a screwdriver out of his pocket; he was tripped and pulled down. The robber was then immobilized on the floor, in prone posture, with the bank clerk pressing the assailant's thorax and an arm locking the neck, while the bank customer was blocking the robber's arms. The immobilization lasted approximately five minutes, per witness testimony. During this period, the robber's behavior escalated; he was agitated, shouting blasphemies, threatening bystanders, and suddenly showed disorganized and inconsistent thought processes and disturbances in speech. When police officers arrived at the scene, the robber was quiet. He was then handcuffed, but while moving him in a supine posture, the robber's face was described as cyanotic. Resuscitation attempts were then started but proved to be ineffective.

Scene inspection revealed bloody fluid on the ground, arising from the mouth and nostrils. Rectal temperature, measured two hours after death, was slightly increased from that expected. Conjunctival petechiae, mouth ulcers, and a small abrasion on the nose were found at external examination, with minor bruises on the arms and legs.

At autopsy, a meticulous dissection of the neck was performed, since choke holding of the robber's neck was reported by witnesses. Minor hemorrhagic infiltration of the soft tissue surrounding the left lesser horn of the hyoid bone was identified, without any fractures. A computed tomography scan with 3D reconstruction confirmed the macroscopic examination results. The lungs were congested and edematous, with foamy fluid in the airways. Heart dissection showed plaques on the right coronary artery (30%) and circumflex artery (50%). Histology revealed contraction bands in the myocardium.

Toxicological analysis was performed on blood, urine, and vitreous humor; gas chromatography/mass spectrometry assessed lethal blood levels of cocaine, benzoylecgonine, ecgonine-methyl-ester, and cocaethylene. Urine and vitreous humor were negative. Cocaine consumption occurred within an hour prior to the attempted bank robbery.

No evidence was found of significant trauma or a natural pathological cause which could independently justify the death. Data resulting from witness testimony, autopsy, and ancillary postmortem analysis allowed the determination of cocaine intoxication as the cause of death; the manner was declared as accidental. The mechanism of death involved a terminal arrhythmia, most likely due to sympathetic sensitization of the myocardium by cocaine and the stressful effects of the attempted bank robbery and the subsequent struggle. It can be speculated that the pre-existing coronary artery disease played a role in the establishment of the arrhythmia and in the failure of the resuscitation attempts.

H73 The Forensic Science Investigations in Recent Cases of Victim's Cannibalism: Reality or Fiction? A Case of Matricide and Review of Literature

Isabella Aquila, MD, Viale Europa, località Germaneto, Policlinico Universitario, S Venuta-Medicina Legale, Catanzaro 88100, ITALY; Ciro Di Nunzio, MFS, PhD*, Magna Graecia University, Viale Europa, Germaneto, Legal Medicine, Catanzaro 88100, ITALY; Silvia Boca, Viale Europa, Catanzaro, ITALY; Francesco Ausania, MD, Largo Francesco Vito 1, Rome, ITALY; Maurizio Saliva, MD, Via Carlo Maria Rosini 51, Pozzuoli 80078, ITALY; Ester de Luca, MD, Viale Europa 88100, Catanzaro, ITALY; Matteo Borrini, PhD, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to describe the impact of forensic science in cases of cannibalism.

This presentation will impact the forensic science community by demonstrating the crucial role of a multidisciplinary approach in a case of matricide in order to demonstrate that cannibalism occurred.

Introduction: Cannibalism is one of the most contentious topics in anthropology and there are many historical reports of cannibalism.^{1,2} The figure of the cannibal as an icon of primitivism took form in the encounter between Europe and the Americas and became a defining feature of the colonial experience in the New World.³ In mythology, religion, and literature, there are many examples of cannibalism that have been passed down over the centuries which do not strike us as shocking as long as they remain fixed in a symbolic context. There is not just one, but many forms of cannibalism.⁴ Today cannibalism is very rare. In a review of the literature, there are no studies which reported cases of parricide and cannibalism. Many studies have analyzed reasons for parricide; some studies have revealed that the parricide may increase with the presence of mental disorders or for the absence of an adequate treatment in subjects with psychiatric disorders.^{5,6} The attackers are usually suffering from schizophrenia with symptoms of active psychosis at the time of the crime.⁷⁻¹³ Less well known are the reasons that bring a murderer to cannibalism of his victim. In particular, in this study, there was cannibalism in the case of matricide.

Case Report: A case of a young man suffering from schizophrenia who killed his mother is reported. The matricide occurred through the use of a single weapon with sharp serrated edges. The body of the victim was found in her apartment. The victim was on the bathroom floor with evident dismemberment of the body. In the kitchen, some small portions of human tissue were found in the pots on the stove, presumably to be eaten. Portions of these human remains were boiled, while other portions were roasted. The technique of bloodstain pattern analysis was employed to detect the presence of small air bubbles in the blood stains imprinted on bathroom tile as by repeated and violent blows against the surface above the victim while still alive. The portions of human tissue found in the kitchen belonged to the victim. Moreover, feces belonging to the murderer was found in the toilet. There were larvae on the stool. Genetic analysis of the larval content showed the presence of the genetic material of the victim. This confirmed that the portions of human tissue found in the kitchen had been eaten by the murderer and therefore it has been scientifically proven that cannibalism had occurred. An autopsy with histopathological and postmortem computed tomography investigations were performed. The analysis of bony evidence revealed the presence of a "Y"-shaped incision from a blade with a serrated edge. In this case report, the examination of the injuries inflicted on the bones of the head allowed a determination that the trauma occurred when the subject was still alive. The histopathological examination of cranial bone showed the presence of edema with intraosseous hematic effusion, while the investigation of other dismembered body parts did not show this histopathological data.

Conclusions: The forensic investigation allowed the determination of the cause and manner of death. In this case, as in the cases of patricide, a correlation with psychiatric disorders was noted, in particular with schizophrenia, in the choice of victim's cannibalism. Therefore, this rare case demonstrated how the multidisciplinary approach in the evaluation of the findings at the crime scene was crucial in obtaining a scientifically proven result.

Forensic Science, Cannibalism, Matricide

H74 Death Following Intravenous Administration of Sucralphate

Henrik Druid, MD, PhD*, Karolinska Institutet, Dept of Forensic Medicine, Retzius v. 3, Stockholm SE-171 77, SWEDEN

After attending this presentation, attendees will understand how sucralphate — a drug used orally to prevent gastric ulcerations — can cause severe complications when administered intravenously and how to identify intravascular presence.

This presentation will impact the forensic science community by presenting a case report which serves as an example of the importance of applying unconventional analyses to answer a particular question in routine postmortem casework.

Sucralphate is a drug used for prevention of gastric and duodenal ulcers as well as for prevention of stress ulcerations of the gastric mucosa, particularly in patients under intensive care treatment for burns, multitrauma, neurosurgery, and more. It is administered orally, typically via a gastric tube, and will exert its effect by binding to the mucosa, where it stimulates factors that enhance the gastric defense barrier, thereby protecting against ulcerations. The many aluminum groups on this large sugar molecule are supposed to be crucial for the cytoprotective effect, similar to other antacids. Aluminium sucralphate has been shown not to enter the blood circulation to any significant amount upon oral administration.

An 83-year-old man underwent surgery for aortic valvular stenosis. After the surgery, bleeding from the gastric tube was noticed. Gastroscopy revealed erosive gastritis and it was decided he should receive tranexamic acid and omeprazol as well as four units of erythrocyte concentrate. In addition, aluminium sucralphate (brand name Andapsin®) was ordered in a dose of 2g (10mL)x3. His condition remained stable until the second day, when he suddenly developed bradycardia and experienced shortness of breath. He was taken to the intensive care unit, where he lost consciousness. Pericardiocentesis revealed no blood in the pericardial sac. Shortly thereafter, he became pulseless and stopped breathing. Resuscitation was unsuccessful. Later, a nurse who was new at the clinic and not experienced with all routines, reported that she was unsure if she had administered sucralphate into the gastric tube or into the central venous catheter just before the patient developed bradycardia.

The case was reported to the police because of suspicion of malpractice and a forensic autopsy was performed. Gross macroscopic findings included heart enlargement and heavy lungs, but no blood in the thoracic or abdominal cavities. Samples were taken for toxicology, including a sample from the left jugular vein/superior vena cava at the position of the intravenous catheter. Analysis for sucralphate was requested. The forensic toxicology laboratory explained that this drug would not be possible to identify by their screening method and that no known method existed for verification analysis of such a large molecule as aluminium sucralphate phosphate. Given the large number of aluminium groups present on the drug molecule, analysis for aluminium was considered a possibility since no or very little amount of this drug should be expected to be found in the blood if the drug was given orally. The department of inorganic chemistry at Umea University, Sweden, was contacted and agreed to analyze aluminium levels in the samples. To this end, both femoral and jugular blood samples were submitted from this patient, as well as blood samples from an additional two patients who later died at the same intensive care unit, although by known causes. One of them had also been administered sucralphate. An empty test tube was also sent for analysis. An accredited method for analysis of aluminium using graphite-oven atomic absorption spectroscopy was performed. The results are shown in the table below.

Case	Al conc (mcg/L)	Sucralphate dose
Present case, jugular blood	8800	2g x 3
Present case, femoral blood	2100	2g x 3
Control patient #1	30	1g x 4
Control patient #2	10	No
Empty test tube	2	No

Microscopy included immunohistochemistry with an anti-fibrinogen antibody, 1:500, and with Vulcan Red as a chromogen. Widespread, intravascular, well-developed networks of fibrin, capturing large numbers of polymorphonuclear cells, typical of extensive micro-embolism, were seen in samples from the lungs and kidneys.

Conclusion: The intravascular microthrombi are an expected finding upon binding of sucralphate to fibrinogen, promoting its aggregation. The extreme increase in aluminum levels in the blood of the patient along with the presence of microthrombi strongly supported the notion that sucralphate indeed had been given intravenously.

H75 Alibi Verification Using Diatoms

Paola A. Magni, PhD*, University of Western Australia, Centre for Forensic Science, Myers St Bldg, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA; Tommaso Pacini, MSc, University of Iceland, Dept of Pharmacology and Toxicology, Hofsvallagata 53, Reykjavik 107, ICELAND; Marco Pazzi, PhD, University of Turin, Dept of Chemistry, Via P. Giuria n.5, Torino, ITALY; Marco Vincenti, MS, Centro Regionale Antidoping, Regione Gonzole 10/1, Orbassano, Torino 10043, ITALY; Ian Dadour, PhD, University of Western Australia, Centre for Forensic Science, 35 Stirling Highway, M420, Nedlands, Western Australia 6009, AUSTRALIA; and Elisa Falasco, PhD, University of Turin, Dept of Life Sciences and Systems Biology, Torino, ITALY

After attending this presentation, attendees will understand the use of diatoms in a forensic case to verify an alibi.

This presentation will impact the forensic science community by utilizing evidence that was previously disregarded but in actual fact contributed to solving a case.

The corpse of a young girl was found on the shore of Bracciano Lake (Rome, Italy) one early morning in November, 2012. The corpse was identified as a girl who disappeared the day before, after she spent a night out with her boyfriend. The relationship between them was known to be turbulent and the boy, when questioned about the events of the night of the girl's disappearance, admitted to having an argument with her. Furthermore, he told the investigators that because of the argument he let the girl out of the car late that night, not far from the lake and a few kilometers from her house. When questioned about the time between letting her out of the car and the discovery of the corpse, he stated that he was at home and had never been at the lake that night.

The autopsy noted there was no sign of violence associated with the body. She had not been sexually abused and the results of the toxicological analyses were negative. The death was found to be as a consequence of natural causes but the results were still controversial. Due to the circumstances surrounding the death, a further investigation was requested to clarify the events of that night. In particular, an investigation was conducted to verify if the boy had been at the lake that night.

The resulting investigation was an analysis of the boy's clothing to determine the presence of diatoms and to identify if the diatom assemblage of the lake could be matched both to his clothes and to the place where the corpse was found.

Diatoms are unicellular organisms that are present in almost all natural aquatic environments such as seas, lakes, rivers, streams, and even puddles of rain water, but are generally absent in tap water. Many species are habitat specific. Diatoms have a hardened silica structure that is resistant to chemical treatments and have morphological features that can be used for species identification. Diatoms can be found in clothing, proving a possible contact with a particular water type in which a specific diatom community is present.

All the garments belonging to the boy underwent a diatom test and samples of both tap water of the house and the water of the lake were used as reference. The glass bottles used to collect the water were sterile to avoid the presence of extraneous diatoms, while each garment collected was placed in a separate bag to avoid possible diatom transfers between items. Formalin was added to both of the reference waters and after settling for 48 hours, the supernatant was discarded. The pellet was first treated with H₂O₂ and then with 10% HCl. This was followed by three washing steps: (1) a 2g-sample of each of the boy's clothes were rinsed in 70% ethanol; (2) each sample was placed in a 50ml plastic tube with 50ml ethanol solution (70% in water) and left in a rotator for 48 hours; and, (3) the cloth was removed and after settling for 48 hours, the supernatant was discarded.¹ The pellet underwent the same treatment as the reference waters.

Samples were mounted with a high refractive index medium and were analyzed with an optical microscope. The species composition was determined from both a subsample from the lake, tap water, and clothing pellet and the species of diatoms were compared and recorded. A large number of diatoms were found in the water samples collected from the Bracciano Lake, while only a single diatom cross-matched with the sample of tap water. Furthermore, diatoms extracted from a number of pieces of clothing belonging to the boy were a positive match with the diatoms collected from Bracciano Lake.

An interesting discovery during this investigation was the identification of the outfit that the boy was wearing the night of girl's disappearance, which happened to be the clothing that was matched to the diatom test.

H76 Sudden Death After Methylprednisolone Sodium Hemisuccinate Injection: A Rare Case of Anaphylaxis

Giuseppe Ruggiero Parente, MD, Viale degli Aviatori 1, Foggia 71121, ITALY; Marco Savito, MD, Viale Degli Aviatori 1, Foggia 71121, ITALY; Furio Martino Patete, Viale degli Aviatori, 1 C/O Medicina Legale, Ospedale C.D'avanzo, Foggia 71121, ITALY; Gaetano Serviddio, MD, PhD, University of Foggia, Dept of Clinical Medicine, Viale Pinto, 1, Foggia 71121, ITALY; and Cristoforo Pomara, MD, PhD, University of Foggia, Dept Forensic Path, University of Malta, Dept of Anatomy, Faculty of Med & Surg Biomedical Sci, Foggia, Misida, Malta 71100, ITALY*

After attending this presentation, attendees will understand a fatal case of anaphylactic shock due to methylprednisolone sodium hemisuccinate in a 19-year-old male, affected by optical neuritis, in treatment with endovenous administration of methylprednisolone sodium hemisuccinate.

This presentation will impact the forensic science community by examining a case that, because of the rarity of anaphylactic shock due to methylprednisolone, underlines the usefulness of the laboratory tryptase enzyme immunoassay, such as a complete immunohistochemical study of all specimens, on blood samples to obtain a correct etiopathogenetic definition in cases of anaphylaxis.

The diagnosis of death from anaphylactic shock is difficult and often misunderstood because it is uncommon. Although anaphylaxis is not a frequent adverse effect of corticosteroid treatment, its diagnosis is very important because of the widespread use of corticosteroids that, due to their efficacy as anti-inflammatory and immunosuppressive agents, are widely used in the treatment of a large number of diseases, such as asthma, allergies, and autoimmune and neoplastic diseases. Adverse reactions due to corticosteroid hypersensitivity, including anaphylaxis (first described in 1974), angioedema, urticaria, generalized cutaneous eruption, and severe bronchospasm occur only in 0.3% of cases involving systemic administration. Corticosteroids probably act as haptens because of their low molecular mass.

The following case concerns a sudden death due to methylprednisolone sodium hemisuccinate administration.

Case Report: A 19-year-old healthy male suddenly presented with a decrease in visual acuity more evident in the right eye. After several clinical and instrumental checks including fundus examination, optical computed tomography, and ocular electrophysiology, a right eye retrobulbar optical neuritis was diagnosed. The patient was started on a treatment with 25mg prednisone tablets. After nine days, the patient showed hyperglycemia (glucose concentration of 379mg/dl) associated with the presence of ketone bodies in the urine. Due to this condition, he was prescribed first metformin and then subcutaneous insulin therapy. After five days, the boy was admitted to the emergency department for the persistence of hyperglycemia (400mg/dl). A diagnosis of diabetic ketoacidosis was made and intravenous insulin therapy and hydration with saline and bicarbonate infusion were administered. The following day, he suspended infusion therapy and started subcutaneous insulin therapy. After ten days, because of the worsening vision, the boy started a three-day endovenous administration of Solu-Medrol® in 250cc saline drip with a slow drip of two hours duration. On the second day, after the daily administration, the patient showed cough and spontaneous urinary loss associated with seizures, stupor, and falling to the ground with subsequent cardiopulmonary arrest. The patient died, despite cardiopulmonary resuscitation efforts. An autopsy was performed 24 hours after death. External examination was unremarkable; internal examination showed cerebral edema with moderate swelling of cerebellar tonsils and bilateral pulmonary edema. Histological and immunohistochemical (CD4, CD15, CD68, CD20, CD3, CD8, and CD45) investigation of brain specimens revealed a diffuse cerebral edema in association with bilateral optical neuritis and chiasmal optic neuritis. Lung samples showed subpleural and interstitial hemorrhage, intra-alveolar and diffuse interstitial edema, and acute stasis; other organs were unremarkable.

The laboratory tryptase enzyme immunoassay on blood revealed a tryptase concentration of 136.50mcg/L (n.v. 0.00-15.00mcg/L), greater than the cut-off value of 45µg/l for the diagnosis of anaphylactic shock. The death was attributed to anaphylactic shock due to methylprednisolone sodium hemisuccinate, most probably due to its excipient.

Corticosteroid, Anaphylaxis, Methylprednisolone

H77 **Body Packers and Body Stuffers: The Role of Cardiac Oxidative Stress on Myocardial Damage**

*Dania De Carlo, MD**, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; *Stefania C. Bello, MD*, Ospedale Colonnello D'Avanzo, viale degli Aviatori, Foggia 71100, ITALY; *Marco Di Paolo*, via Roma 55, Pisa 56100, ITALY; *Carmela Fiore, MD*, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; *Francesca Maglietta*, Viale degli Aviatori, Foggia, ITALY; *Angelo Montana, MD*, University of Catania, Via Santa Sofia, Catania, ITALY; *Antonio Oliva, MD, PhD*, Largo Francesco Vito 1, Rome, ITALY; *Laura Panata*, Via del Giochetto, Perugia 06126, ITALY; *Daniela Cerretani, BS*, University of Siena, Policlinico Le Scotte Strada delle Scotte, Siena, ITALY; and *Irene Riezzo, PhD*, Univ of Foggia, Osp D'Avanzo, Dept of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71100, ITALY

The goal of this presentation is to elucidate the mechanisms of acute cardiac toxicity for very high blood concentrations of cocaine such as those found in dead body packers and body stuffers. Presented are seven cases of death from cocaine overdose in the absence of other psychotropic substances; the results of the immunohistochemical and biochemical analysis used to study the role of oxidative stress in the myocardial damage.

This presentation will impact the forensic science community by emphasizing the problem of acute myocardial damage and the necessity of understanding the mechanisms of acute cocaine cardiotoxicity in order to explore a clinical-translational approach to this problem.

The “body-stuffer,” usually small-time drug user or dealer, is a person who, when intercepted by authorities, ingests the drug coarsely packed in pouches made from scraps of polyethylene, cellophane, aluminum foil, or paper. These packages can easily open, causing acute poisoning syndromes.

Case 1: A 29-year-old woman in police custody was referred for a general disease. She was admitted to the emergency department but a fatal cardio-respiratory arrest occurred suddenly. No foreign material was detected from a total-body computed tomography scan. The autopsy revealed a single, open plastic bag in the gastric lumen and several deep ulcers of the gastric mucosa. Cocaine and benzoylecgonine were detected in the blood (1.72mcg/ml and 4.31mcg/ml, respectively) and in the urine (5.74mcg/ml and 43.23mcg/ml, respectively).

Case 2: A 32-year-old man was found in cardiopulmonary arrest in an apartment. During the autopsy, ten single plastic bags were found in the intestinal lumen and necrosis of the intestinal wall was detected. The concentration of cocaine in urine was 147mcg/ml.

Case 3: A 34-year-old man was found in cardiopulmonary arrest in an apartment and a spoon with white powder was found next to him. The autopsy revealed a single plastic bag in the esophagus. High levels of cocaine and benzoylecgonine in his blood (23.76mcg/ml and 6.57mcg/ml, respectively) and in urine (230.42mcg/ml and 737.27mcg/ml, respectively) were detected.

Case 4: A 30-year-old man was found in a car. A single opened plastic bag in the gastric lumen was found at the autopsy. High levels of cocaine in his urine and blood were found (42.29mcg/ml and 3.00mcg/ml, respectively) and the concentration of benzoylecgonine in his blood and in urine were 11.09mcg/ml and 92.50mcg/ml, respectively.

Case 5: A 20-year-old female ingested a plastic bag with cocaine and after two hours developed convulsions and respiratory failure. The autopsy revealed a single plastic bag in the gastric lumen. Cocaine and benzoylecgonine in her blood (7.03mcg/ml and 10.67mcg/ml, respectively) and urine (816.92mcg/ml and 540.17mcg/ml, respectively) were detected.

Case 6: A 35-year-old man was found in his car. An autopsy was performed and a broken plastic sachet was found in the intestinal lumen. The levels of cocaine in his urine and in blood were 11.41mcg/ml and 0.10mcg/ml, respectively, while the levels of benzoylecgonine were 1,609.26 mcg/ml in his urine and 8.87mcg/ml in his blood.

Pathology/Biology Section - 2015

Case 7: A 17-year-old man ingested a plastic bag with cocaine to avoid arrest. During the autopsy, the package was found in the gastric lumen. In his blood, the following concentrations, 98.1mcg/ml of cocaine and 86.1mcg/ml of benzoylecgonine, were detected; in his urine, their concentrations were 10mcg/ml and 4.2mcg/ml, respectively. At the autopsy, cerebral and pulmonary edema, slight heart hypertrophy, and multiple bluish areas in the ventricular wall were described. The histological investigations confirmed the macroscopic findings and revealed diffuse foci of contraction band necrosis. An immunohistochemical study with Ab anti IL-1 β , IL-6, TNF- α , IL-8, b1 adrenergic receptors, NF-kB, Bcl-2, and apoptosis was performed. The biochemical examination revealed an alteration of antioxidant systems, the reduction of the GSH/GSSG ratio and a significant increase of MDA.

Body Stuffer, Acute Cocaine Cardiotoxicity, Cardiac Oxidative Stress

H78 Crystallins Aging Process and Related Post-Translational Modifications (PTMs) in Determination of Human Age

*Hanqing Wang**, 1600 S Joyce Street, Apt 119, Arlington, VA 22202; and *Mehdi Moini, PhD*, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20052

After attending this presentation, attendees will learn that forensic chemists can use the techniques presented here to identify the age of unknown deceased persons by using state-of-the-art technology.

This presentation will impact the forensic science community by presenting a method for determining human age by Post-Translational Modifications (PTMs) in lens crystallins as a novel forensic method for fast and potentially accurate age determination of unknown deceased persons.

The increase in the proportion of D-isomer of Aspartic Acid (Asp) relative to the natural occurring L-isomer (i.e., racemization) has been widely used in archaeology and geochemistry as a tool for dating; however, its application in forensic science is has been limited. Among the methods available to identify the age of the deceased is the analysis of the D/L-Asp ratio in human teeth; however, this can take a long time due to the fact that the samples must be dissolve. In comparison, the human eye lens is relatively easy and quick to analyze and could be used as a complementary technique to already existing methods. Among the applications of this dating method is the age determination of unknown casualties of mass disasters.

Human lens protein crystallins have shown extraordinary potential as biological clocks; over the human lifetime, the lens accumulates these proteins with no turnover. This key characteristic indicates that in healthy people most PTMs of crystallins are mainly due to aging. In this study, several important PTMs will be investigated, including deamidation, racemization, and aggregation (disulfide bond formation). Racemization primarily occurs in aspartic acid, while deamidation is one of the most frequently occurring PTMs of asparagine and glutamine. Moreover, disulfide bond formation leads to the formation of water insoluble proteins resulting in protein precipitation and cataracts.

At this stage, this study has used carp eye lens as a model to develop techniques for detecting eye protein PTMs. The developed method for crystallins analysis will be then applied to human crystallins in collaboration with George Washington University Medical School.

To extract the crystallins, decapsulated lenses were homogenized and dissolved in buffer. For deamidation and aggregation studies, proteins were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and desirable bands were cut, reduced, alkylated, and digested by different enzymes including trypsin. The digested solution was analyzed using nano-liquid chromatography with tandem mass spectrometry.

The presented method for determining human age by PTMs in lens crystallins gives forensic scientists a method for fast and potentially accurate age determination of unknown deceased persons.

Dating Human, Eye Lens, Proteomics

H79 **Hydrophilic Polymer Embolization: A Common Incidental Finding at Medical Autopsy**

*Stephanie M. Richards**, University of Maryland School of Medicine, 655 W Baltimore Street, Baltimore, MD 21201; *Julia Choi*, 22 S Greene Street, Baltimore, MD 21201; *Allen Burke, MD*, University of Maryland School of Medicine, 22 S Greene Street, NBW51, Baltimore, MD 21201

After attending this presentation, attendees will: (1) understand what hydrophilic polymer is and how and why it is used in the medical community; (2) be able to identify hydrophilic polymer emboli and the associated tissue reactions on histology slides; and, (3) become familiar with the potential medicolegal implications of hydrophilic polymer embolization.

This presentation will impact the forensic science community by providing education and improving competence in identifying a common, but only recently described, autopsy finding.

Background: Hydrophilic polymers are substances that are commonly applied to the surface of vascular catheterization devices in order to reduce friction and decrease vascular injury related to cannulation. These polymers have the potential to detach and travel within the bloodstream, causing hydrophilic polymer embolization. These basophilic, often coiled, and focally granular emboli are commonly detected in the lungs at autopsy in patients who have undergone cannulation with large-bore vascular catheters prior to death. Hydrophilic polymer embolization is most commonly an incidental finding but associated complications have been reported.

Design: A retrospective selective autopsy review was conducted at a tertiary care center to identify cases of hydrophilic polymer embolization in the lungs during a 20-month period (November 2012 to June 2014). Autopsy cases were selected for review based on likelihood of detecting emboli; only cases involving large-bore vascular catheterization (central venous catheter, Peripherally Inserted Central Catheter (PICC) line), Extracorporeal Membrane Oxygenation (ECMO), angiography, etc.) prior to death were included for review. Original hematoxylin- and eosin-stained slides of lung tissue were examined for the presence of hydrophilic polymer emboli. The total number of slides containing hydrophilic polymer emboli, number of emboli per slide, and tissue reaction to the polymer were also noted. These histological findings were subsequently correlated with clinical information obtained prior to death.

Results: A total of 33 autopsy cases were reviewed (ages: 2.5 months to 78 years; 19 males). In all cases, the decedents had at least one medical procedure involving large-bore venous catheterization prior to death. Of these, nine cases (27%; ages: 2.5 months to 72 years; four male) showed histologic evidence of hydrophilic polymer emboli within the lung tissue. Six of these cases (67%) demonstrated unilateral lung involvement; one case (11%) demonstrated emboli within two lobes of the same lung. In two cases (22%), three lung lobes showed histologic evidence of hydrophilic polymer embolization. Two cases (22%) demonstrated no evidence of tissue reaction to the polymer. Five cases (56%) revealed macrophages and/or giant cells surrounding the polymer; however, in two cases (22%), a more significant reaction was identified, including macrophages and/or giant cells, vascular intimal proliferation, and in one case (11%), thrombus. On medical record review, none of the nine cases were associated with any morbidity or mortality directly linked to hydrophilic polymer embolization.

Conclusion: Hydrophilic polymer embolization, particularly in the lungs, is a common finding at autopsy in patients that have undergone large-bore vascular catheterization prior to death. This finding is largely incidental; however, histologic evidence of tissue reaction can be seen in many cases and rare cases of associated morbidity and mortality have been reported. As such, polymer emboli represent a newly-recognized iatrogenic complication with potential medicolegal implications.

Hydrophilic Polymer, Embolization, Catheterization

Pathology/Biology Section - 2015

H80 Fatalities Associated with Aldicarb

Hannah C. Jarvis, MRCS*, 3398 Wayne Avenue, Apt C12, Bronx, NY 10467; and Carolyn A. Kappen, MD, OCME, City of New York, 1225 Morris Park Avenue, Bronx, NY 10461

After attending this presentation, attendees will better understand the rodenticide aldicarb, including its intended uses, toxic effects, and because of its availability in certain communities, its use as a suicide modality.

This presentation will impact the forensic science community by providing information on aldicarb, which may be easily obtained and used illegally in households for pest control within the United States. Aldicarb has been intentionally ingested and poses a risk for accidental overdose in adults and children due to improper packaging and its accessibility to small children. Aldicarb is often admixed with food and placed on floors and cupboards for rats and cockroaches to consume.

Aldicarb is a rodenticide, insecticide, and nematicide. It is a systemic carbamate that is a potent cholinesterase inhibitor.¹ Symptoms of aldicarb intoxication include miosis, nausea, vomiting, diarrhea, diaphoresis, headache, and blurred vision.² The mechanism of death is often respiratory depression and pulmonary edema.

The poison is produced in Latin American countries, such as the Dominican Republic and Mexico. Aldicarb is still widely used as a commercial pesticide in farming. The use of aldicarb as a pesticide in households is illegal in the United States, as directed by the Environmental Protection Agency. In communities with large Hispanic populations such as New York City, aldicarb is often brought from countries of origin by families and vendors because of its desired efficacy as a rodenticide.³

A review of the toxicology database from the Office of Chief Medical Examiner City of New York identified two fatalities where aldicarb was detected. In both cases, aldicarb directly contributed to the cause of death.

Case 1: A 60-year-old man was found dead in his bed at home. The decedent had been depressed, expressed suicidal ideation, and had been abusing alcohol. Initial investigation revealed a coffee mug containing granules on the bedside table. Further investigation of the scene by the investigator and a family member revealed an envelope labeled “Tres Pasito,” along with several empty vodka bottles, which were found in a closet. A foam cone was described by family. At autopsy, several granules were noted on the face, chest, and in the gastric contents. Advanced atherosclerotic cardiovascular disease was also noted at autopsy.

Case 2: A 44-year-old woman was taken to the emergency department, having been found unresponsive at home. The decedent had a history of depression with suicidal ideation. The family reported to the treating physician that an open package of rat poison they referred to as “Tres Pasito” was found near the woman. Despite approximately one day of resuscitative measures, the patient did not survive. At autopsy, innumerable tan flakes and granules were found in the esophagus, stomach, and small intestine. Liver necrosis, acute tubular necrosis, pulmonary edema, and acute diffuse anoxic ischemic encephalopathy were diagnosed clinically and confirmed by autopsy.

In both autopsies, toxicological analysis of the postmortem blood, urine, and gastric contents by liquid chromatography revealed the presence of aldicarb. The cause of death was acute aldicarb intoxication and the manner of death in both cases was suicide. Both decedents had intentionally ingested the poison.

Aldicarb is usually not included in routine toxicology panels. It therefore may easily be overlooked by a forensic pathologist or a clinician. A thorough scene investigation and detailed history from the family, including questions regarding depression and past suicidal intent, may provide answers that raise the level of suspicion to warrant further and more specific toxicologic analyses.

Clinically, the presenting anticholinergic symptoms should always remind a treating physician to include aldicarb in the differential diagnosis, as there are many communities in the United States where aldicarb is easily purchased at the neighborhood market.

H81 An Extremely Enjoyable Rave Party Resulting in a Fatal Sleep: The Reliability of Postmortem Computed Tomography in a Case of Crush Asphyxia

*Serenella Serinelli, MD**, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena 336, Rome, Lazio 00169, ITALY; *Massimiliano dell'Aquila, MD*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Lorenzo Gitto, MD*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Aniello Maiese*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; and *Giorgio Bolino, MBBS*, Viale Regina Elena, 336, Rome 00169, ITALY

After attending this presentation, attendees will understand the importance of Postmortem Computed Tomography (PMCT) in cases of crush asphyxia, with special regard given to the presence of gas (pneumothorax and subcutaneous emphysema) in corpses in a good state of preservation.

This presentation will impact the forensic science community by showing how PMCT allows forensic pathologists to clarify the causes of death and to verify the presence of vital signs even before the traditional autopsy.

The use of PMCT is growing in the field of forensic pathology as a supplement to the traditional autopsy because it is an objective and non-invasive approach. In particular, CT is an extremely reliable diagnostic instrument in several important areas of forensic pathology, such as identification of fractures, foreign bodies, and gas.

The corpse of a 28-year-old man was found under a car. According to the statement of the car's owner, in the early morning, he started his car but the vehicle did not move easily. Therefore, he exited the vehicle and found an unresponsive man lying on the ground under the car. Rescuers jacked up the car and extracted the corpse. According to the circumstantial evidence, the victim had been at a rave party the night before, where he had been heavily drinking.

A preliminary PMCT examination was performed five hours after the death. The following features were described on the CT report: atlo-axial dislocation, bilateral sternoclavicular joint dislocation, and multiple vertebral and rib fractures. On the upper part of the thoracic cavity, an anterior bilateral pneumothorax was present together with diffuse subcutaneous emphysema of the upper anterior trunk.

At the external examination, an ecchymotic mask was observed. Multiple abrasions and lacerations were irregularly widespread over the entire body surface. On the left side of the left nipple, a circular-shaped imprint abrasion was observed. Palpation of the skin over the anterior chest showed evidence of crepitus. The specific autopsy test for pneumothorax was performed, showing a negative result. Rib fractures were confirmed, surrounded by hemorrhage of the soft tissues. Lacerations of the parietal pleura, multiple tears of the lungs, and a left hemopneumothorax were found.

Toxicological analyses showed a concentration of ethanol of 351mg/dL in the peripheral blood and 387mg/dL in the urine. Immunohistochemistry analyses on the left hemithorax imprint abrasion were performed, showing a positive reaction to glycophorin.

In this case, compression of the chest interfered with the respiratory movements. Moreover, it led to severe injuries of the chest wall, resulting in bilateral rib fractures and tears of the lungs with hemopneumothorax. The air then moved into the subcutaneous tissues of the thorax due to a pressure gradient. Since a subject needs to be alive to realize this gradient, pneumothorax and subcutaneous emphysema are vital signs.

The well-timed PMCT examination allowed identification of these vital signs before the traditional autopsy. According to these findings, a specific autopsy technique to identify pneumothorax was performed with negative results, probably due to the small amount of air in the pleural cavities. Thus, PMCT can be considered as the most sensitive method for the identification of body gas, with special regard to small size pneumothorax. Moreover, the circular abrasion located on the left thorax was analyzed by immunohistochemistry, showing a positive reaction to glycophorin. Hemorrhages in the soft tissue surrounding the rib fractures were observed, confirming that the subject was still alive before being run over by the car.

In this case, PMCT was useful to clarify the mechanism of death and to identify signs of vitality before the autopsy examination. Since the autopsy test for pneumothorax identification was negative, without postmortem CT the presence of pneumothorax would definitely have been unrecognized.

Pathology/Biology Section - 2015

The main limitations of PMCT in case of pneumothorax and subcutaneous emphysema are the preservation status of the corpse and the employment of cardiopulmonary resuscitation procedures. A corpse in a good state of preservation, together with detailed circumstantial evidence and crime scene investigation, could allow the forensic pathologist to clarify the cause and mechanisms of death using only PMCT.

Postmortem Computed Tomography, Pneumothorax, Crush Asphyxia

Pathology/Biology Section - 2015

H82 3D Body Surface Documentation in Forensic Pathology

*Petra Urbanová, PhD**, Kotlarska 2, Brno 611 37, CZECH REPUBLIC; *Petr Hejna, PhD*, Charles University in Prague, Šimkova 870, Hradec Kralove 500 38, CZECH REPUBLIC; and *Mikolas Jurda, MSc*, Masaryk University, Kotlarska 2, Brno 61137, CZECH REPUBLIC

After attending this presentation, attendees will understand the cost and benefit of employing innovative 3D body surface documentation techniques in the course of forensic postmortem investigation; they will comprehend technological and methodological advances that allow documenting physical evidence in 3D in a rapid, affordable, yet photorealistic and accurate manner.

This presentation will impact the forensic science community by presenting results that advance currently available documentation techniques employed in the course of routine forensic postmortem examinations.

For the last few years, several projects have invested in establishing image-guided postmortem examination in the framework of forensic pathology — utilizing either medical imaging technologies (Computed Tomography (CT), magnetic resonance imaging) or optical surface scanning. Cross-sectional and surface data are both stand-alone techniques which bring a number of benefits but also a few shortcomings into postmortem examinations. While CT-based images have the capacity to generate a 3D model of any internal structure, under the condition that the contrast between two neighboring tissues or structures is sufficient, they provide little or no information about surface coloring (bruises, lesions), spots, or subtle morphological interferences. Optical surface models, in contrast, lack information on what is going on beneath the surface, but feature high-resolution geometry and surface color information.

Several 3D surface technologies, in particular photogrammetry and optical and laser scanning, have recently advanced into affordable, flexible, and accurate techniques involving a reasonably long learning curve; however, forensic postmortem investigation as performed on a daily basis has not benefited from their full potentials and the currently utilized methods are far behind what 3D surface documentation can provide. Conventionally, 2D photography presents the gold standard utilized throughout the entire process of postmortem examination, documenting the pre-autopsy state of preservation of the corpse, the presence of unique somatic traits or perishable findings, and injuries and/or pathological changes; however, photography discards surface depth — information highly valuable in terms of damage assessment or trait uniqueness.

In this study, two approaches to 3D external body documentation were tested — traditional digital camera-based photogrammetry combined with commercial photo-scan software and stereophotogrammetry-based scanner VECTRA H1®, a novelty product among portable hand-held surface scanners. In order to conduct the study, two forensic cases admitted for postmortem examination at the Department of Forensic Medicine, Hradec Králové, Czech Republic, were selected. A 63-year-old male, who died of traumatic, self-inflicted injuries (suicide by hanging) and a 63-year-old male diagnosed with heart failure. Both cases were photographed in 360° manner with a digital camera mounted on a tripod. Altogether, 35 to 70 images per case were taken, corresponding to 20 to 40 minutes of capturing time. Approximately the same time was required to document the body surface with the hand-held scanner, where up to 120 scans were taken.

The optical surface scanner proved itself to be a useful tool for being able to document small-to-large areas of the body surface. As not being specifically designed to scan objects on a larger scale, post-processing requires rather time-consuming manual image alignment; however, the device produced high-resolution 3D images, comparable in quality to any professional digital camera. The photogrammetry also provided photorealistic records of body surface capable of capturing, for instance, ligature marks, tattoos, and skin lesions in high quality. Moreover, the utilized software was able to create the whole body 3D surface mesh automatically; however, both methods failed when the surface was covered with body hair or reflective, moist areas were being documented.

In conclusion, both methods produce realistic, actual-size, or easy-to-calibrate 3D surface models useable as an advanced method of postmortem documentation and were easily fit to be the subject of further examinations, such as 3D mesh comparison or indirect measurement (e.g., body measurements, angles of penetrations). Digital 3D data can be easily archived, transported, and shared between laboratories; they provide a real-time access for re-examination of physical evidence. Furthermore, no requirements for calibration or operating skills make them ideal to be easily integrated into a daily workflow.

3D Body Scanning, Image-Guided Examination, Photogrammetry

Pathology/Biology Section - 2015

H83 Postmortem Changes on Computed Tomography (CT) Can Assist With the Diagnosis of Biliary Tract Disease

Michael J. Pickup, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON, CANADA*

After attending this presentation, attendees will gain an appreciation for some of the differences in postmortem imaging and clinical diagnostic imaging; specifically, the impact of postmortem artifacts and changes on diagnosis and forensic examination.

This presentation will impact the forensic science community by illustrating a technology-based example of forensic theory — namely that, in some circumstances, the changes that occur and progress after death (as visualized on postmortem Computed Tomography (CT)) can be the key to stepping backward to determine how and why some people die.

Postmortem changes such as hypostasis in the lungs, hematocrit effect in the dural sinuses, and air collections caused by gas-forming organisms can be distracting to pathologists and radiologists assessing Postmortem Computed Tomography (PMCT) images. Much like postmortem artifacts on gross examination, these findings can obscure, mimic, or be intensified by real pathology. It is important for forensic pathologists to know the difference and be able to draw inference from these findings in order to reinforce their conclusions.

Reported are two cases of sudden unexpected death where biliary tract disease was suspected by localized gas collections following PMCT and confirmed at autopsy. The first involved a 70-year-old woman with a short history of bilious vomiting with sudden collapse. In another case, a 55-year-old man was found dead sitting upright in his bathtub. At the time of discovery, he was slumped over, but his face was not submerged. For two days he had not been feeling well, but did not seek medical attention. In both cases, the postmortem interval to CT was less than ten hours.

Dramatic pneumobilia was noted on PMCT of both cases in the absence of putrefactive changes elsewhere. The first case also showed an obstructive pattern in the small bowel with dilatation and air-fluid levels and, on further examination, a large obstructing ovoid structure was seen in the jejunum. Gallstone ileus was confirmed at autopsy with a fistula between the gallbladder and duodenum. Pneumobilia is attributed to gas from the small bowel gaining access to the biliary tract. In addition to pneumobilia, the second case showed fat stranding in the vicinity of the gall bladder bed, but no other significant findings. The common bile duct was dilated and ascending cholangitis was detected by histology. Pneumobilia in this case is attributed to fermenting processes of gas-forming organisms in the biliary tract.

These cases illustrate the fact that not all postmortem changes seen on CT imaging should be discounted. Occasionally, regional differences in postmortem changes or artifacts can be leveraged to guide specialized dissection and sampling at autopsy. For this reason, postmortem changes must be assessed in the context of the clinical history, external examination, the postmortem interval, their extent and localization in the body, as well as the internal autopsy findings.

Postmortem CT, Forensic Pathology, Postmortem Artefacts

H84 Idiopathic Arterial Calcification of Infancy: A Case Report With Postmortem Computed Tomography (PMCT) and Histologic Findings

Zabiullah Ali, MD*, OCME, 900 W Baltimore Street, Baltimore, MD 21223; Pamela E. Southall, MD, OCME Baltimore, 900 W Baltimore Street, Baltimore, MD 21223; and David R. Fowler, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223

After attending this presentation, attendees will understand the rare genetic disorder of Idiopathic Arterial Calcification of Infancy (IACI) and advanced radiographic, gross, and histologic findings.

This presentation will impact the forensic science community by describing the different pathological and clinical diagnostic modalities and by increasing awareness of this rare genetic disorder.

This presentation reports the Postmortem Computed Tomography (PMCT) and histologic findings of IACI, a rare genetic disorder with approximately 180 cases reported in the literature. IACI is characterized by extensive generalized arterial calcification and intimal proliferation of large- and medium-sized arteries. In 75% of cases, the affected infants are either homozygous or compound heterozygous for an Ectonucleotidepyrophosphatase/Phosphodiesterase 1 (ENPP1) gene mutation. ENPP1 is a cell surface enzyme that generates extracellular pyrophosphate, which regulates vascular smooth muscle differentiation and inhibits soft tissue calcification. The critical vascular stenosis and reduced vessel compliance in IACI causes severe heart failure with hydrops fetalis, hypertension, postnatal cardiomegaly, respiratory failure, and myocardial infarction. Most affected infants are diagnosed at autopsy. *In utero* diagnosis of IACI is based on the presence of dystrophic calcifications by fetal echocardiography. Although several cases of prolonged survival with persistent cardiovascular sequelae have been reported, the majority of affected infants will not survive beyond six months of age, especially when coronary arteries are involved. Although a curative treatment for IACI and medical management of cardiovascular effects has generally been unsuccessful, the use of prostaglandin E1 and bisphosphonate such as etidronate, a chelating agent, have been used to treat hypertension and to prevent and reduce further arterial calcification, respectively. In addition, spontaneous remission of the disorder has been reported.

An infant was the first born to an 18-year-old Caucasian female at 37 weeks and 4 days gestation. The prenatal care, which started at 11 weeks gestation, was reportedly unremarkable. Family history was remarkable for three miscarriages involving her paternal half-brother, a neonatal death to a paternal aunt, and a maternal aunt with two miscarriages. The baby was born vaginally with some difficulty in extraction with left shoulder dystocia and asymmetric Moro reflex. The arm movement rapidly improved, but she still had asymmetric Moro reflex at the time of discharge two days after delivery. The post-discharge course was unremarkable with normal feeding and weight gain. Two days before her death, she was noticed to be more restless and fussy and appeared to be straining and stretching her legs, but her feeding was still normal. She was found unresponsive on the 20th day of her life.

As per routine protocol, a full-body PMCT was performed at the Office of the Chief Medical Examiner in Baltimore, which showed extensive bilateral calcification of the following arteries: carotid and its facial branches, subclavian, axillary, brachial, ulnar, radial, aorta, all coronaries, main pulmonary and distal branches, intercostal branches, mesenteric, splenic, renal, common iliac, internal and external iliac, femoral, and tibial. Additionally, significant cardiomegaly with dilated chambers was noted.

The gross examination showed a normally developed female infant, weighing 2,500 grams and approximately 52cm long. The review of organ systems was remarkable for hepatosplenomegaly, palpable calcifications throughout the vascular system, cardiomegaly (42 grams, normal predicted weight 24 grams), four chamber dilatation, and bilateral remote cerebellar infarcts.

Histologic sections of the cardiovascular system showed biventricular circumferential subendocardial acute infarction with wavy and hypereosinophilic fibers and acute inflammatory infiltrates, diffuse calcification of internal elastic laminae and significant luminal narrowing with intimal proliferation in all three coronary arteries, calcified intimal plaques, and calcification of internal elastic lamina with marked intimal proliferation. Microscopic sections of the lungs showed diffuse calcification of internal elastic laminae of large- and medium-sized pulmonary arteries and intimal proliferation. The review of other organ systems was unremarkable, except for calcifications of periadrenal and perilyngeal small vessels. The cause of death was certified as cardiac arrhythmia due to IACI.

Early screening and genetic counseling are recommended in future pregnancies of all affected families.

IACI, Postmortem CT, ENPP1

Pathology/Biology Section - 2015

H85 A Prospective Double-Blinded Comparison of Autopsy and Postmortem Computed Tomography (PMCT) for the Evaluation of Pediatric Trauma Deaths

*Sarah Lathrop, DVM, PhD**, Office of the Medical Investigator, 1 University of New Mexico, MSC 07 4040, Albuquerque, NM 87131; *Gary M. Hatch, MD*, University of New Mexico, Rad-Path Ctr for Forensic Imaging, MSC 07 4040, 1101 Camino de Salud, NE, Albuquerque, NM 87102; *Chandra Gerrard, BS*, Office of the Medical Investigator, Rad-Path Ctr for Forensic Imaging, 1101 Camino De Salud, NE, Albuquerque, NM 87131; *Susan Williamson, MD*, University of New Mexico, Dept of Radiology, 2211 Lomas Boulevard, NE, Albuquerque, NM 87106; *Jan Price, RN, MSA, AAAM Injury Scaling*, PO Box 4176, Barrington, IL 60011; *Kathleen M. Lopez, MD*, Radiology Associates of Albuquerque, 4411 The Way, Ste 150, Albuquerque, NM 87109; *Sam W. Andrews, MD*, Office of Medical Investigator, 1101 Camino de Salud, NE, Albuquerque, NM 87102; *Ross E. Zumwalt, MD*, Office of Medical Investigator, 1 University of New Mexico, MSC 074040, Albuquerque, NM 87131-0001; *Ian Paul, MD*, 4108 Dietz Court, NW, Albuquerque, NM 87107-3206; *Jamie Elifritz, MD*, University of New Mexico, Diagnostic Radiology, MSC-10 5530, Albuquerque, NM 87131; and *Kurt B. Nolte, MD*, Radio-Path Ctr for Forensic Imaging, Office of Medical Investigator, MSC07 4040, 1 University of NM, Albuquerque, NM 87131-0001

After attending this presentation, attendees will understand how and when PMCTs can supplement or supplant autopsy in pediatric trauma deaths and how the two procedures compare in recognizing injuries and determining cause of death in these cases.

This presentation will impact the forensic science community by offering an alternative or supplement to autopsies for specific types of pediatric deaths.

Given rapid advances in radiologic imaging technology, these modalities might offer an alternative to autopsy in certain types of deaths. In order to better understand when PMCT could be utilized to either replace or supplement traditional autopsies for children ages five years and younger dying of trauma, autopsy reports and PMCT findings from a prospective cohort of these deaths investigated by the New Mexico Office of the Medical Investigator between 2011 and 2013 were compared. Each decedent's autopsy report, completed by a pathologist blinded to the PMCT results, and full-body PMCT report, completed by pediatric radiologists blinded to autopsy results, were coded by a certified Abbreviated Injury Scale (AIS) coder. The results were entered into a shared electronic database (REDCap). Autopsy and PMCT results were reviewed in tandem for each case by a forensic pathologist and radiologist who were not involved in the original assessment of the case and each injury on each report was classified as being a match between autopsy and PMCT, missed and should have been seen (false negative, category 1), or outside the usual range of the alternative modality (category 2). Total numbers of injuries found per procedure, Maximum AIS (MAIS) score by region, cause of death as determined by each procedure, and numbers of "misses" were calculated and compared.

Fifty-five pediatric deaths with complete autopsies and PMCT scans were reviewed, with 64% (35/55) of the decedents male, a median age of one year, and an over-representation of American Indian decedents (15/55, 27%) compared to New Mexico's general population (10% American Indian). Forty-seven percent of deaths were in children under the age of one year. The most common cause of death was suffocation while sleeping (18/55, 32.7%), followed by motor vehicle crashes (12/55, 21.8%). Nine deaths (16%) were the result of homicidal violence. In most of the cases (82%), the cause of death was determined to be correct for both autopsy and PMCT. In nine cases (16.4%) the autopsy cause of death was deemed correct by the review panel and PMCT cause of death incorrect, with the converse being true in one case (1.8%). The calculated Injury Severity Score (ISS) was the same for autopsy and PMCT reports in 13 cases (24%), but was more severe when calculated from autopsy results in 33 (60%) of the reviewed cases. Autopsies revealed 335 total injuries, and PMCT detected 267 injuries, with 120 of these determined to be matches between modalities, leaving 482 unique injuries. Overall, 153 injuries seen on autopsy should have been seen on PMCT (31.7%) and 106 injuries (22%) seen on PMCT should have been seen on autopsy. An additional 37 injuries (7.7%) were determined to be outside of the scope of an autopsy and 54 injuries (11.2%) were outside the imaging capability of PMCT. The highest percentages of false negatives for PMCT were for external findings and head injuries (48% and 32%, respectively) and the highest occurrence of false negatives for autopsy were in the chest and extremities (35% and 23%, respectively). Comparing MAIS scores by region, the agreement between autopsy and PMCT ranged from fair (external, kappa=0.34) to almost perfect (extremities, kappa=0.98). MAIS scores for other regions demonstrated moderate to substantial agreement.

Pathology/Biology Section - 2015

While neither modality is perfect, both autopsy and PMCT can be successfully used to correctly determine the cause of death in pediatric trauma cases. Consequently, PMCT can supplant autopsy in certain cases; however, the most detailed identification of injuries in fatal pediatric trauma comes from combining autopsy with PMCT and would be the ideal approach for pediatric homicides. False negatives will be fewer with the use of autopsy for head injuries, while PMCT improves the opportunity to identify chest and extremity injuries. In most cases, the severity of injuries by region agreed well between procedures.

Pediatric Injuries, Autopsy, Computed Tomography

H86 Micro-Computed Tomography (Micro-CT) Features of Laryngeal Fractures in a Case of Fatal Manual Strangulation

*Paolo Fais, MD**, Via Falloppio 50, Padova, ITALY; *Chiara Giraud, MD*, Via giustiniani 2, Padova, ITALY; *Renzo Giordano, MD*, Dolo Hospital - Unit of Pathology, Via XXIX Aprile 2, Dolo (VE), CA 30031, ITALY; *Federica Bortolotti, PhD, MD*, Dept Medicine & Public Health, Policlinico GB Rossi, P. le Scuro No. 10, Verona 37134, ITALY; *Diego Miotto, Radiology Section, Dept of Medicine, Univers, Via Giustiniani 3, Padova, AA 35121, ITALY*; and *Franco Tagliaro, PhD, MD*, Dept of Medicine & Public Health, Policlinico GB Rossi, P. le Scuro No. 10, Verona 37134, ITALY

After attending this presentation, attendees will be aware of a new application of micro-Computed Tomography (CT) for dealing with the identification of the signs of pressure of the neck in cases of subtle manual strangulation.

This presentation will impact the forensic science community by suggesting a novel approach for the identification of laryngeal fractures by means of micro-CT analysis.

It is widely accepted that there are no specific or fully determinate signs of asphyxia. In cases of subtle fatal neck compression, postmortem findings on external examination of a body as well as on autopsy may vary considerably depending on the type of violent trauma, the strength of the resistance exerted by the victim, and on the intensity and duration of neck compression. Based on the detection of a combination of morphological hallmarks such as external injuries to the skin, hyoid or laryngeal fractures, hemorrhages of the overlying soft tissues, and subconjunctival petechiae, the diagnosis of homicidal neck compression is generally accepted.

A case is presented of a 45-year-old schizophrenic patient found on the floor of the bedroom of a psychiatric ward in cardiopulmonary arrest. The patient was successfully resuscitated; nevertheless, brain death was declared after two days in a vegetative state. The roommate of the deceased, who was also schizophrenic, stated that “the voice of God told me to kill my roommate” and death occurred after a prolonged scuffle. The body showed only vague signs of violence at external inspection (i.e., a subtle bruise on the forehead and a minute scratch on the left arm).

At autopsy, the identification of subepicardial petechiae and moderate pulmonary emphysema were not useful for the diagnosis of asphyxial death because these signs might be related to resuscitative maneuvers with prolonged artificial ventilation. Since focal hemorrhagic infiltration of the tracheal mucosa and the superior horns of the thyroid cartilage were observed, a CT scan of the entire larynx was performed, with the goal of identifying laryngeal fractures. Moreover, both superior horns of the thyroid cartilage were analyzed thorough a micro-CT, a radiological technique for tissue analysis with a spatial resolution of a few microns. The 3D reconstruction allowed for identification of multiple cartilage fragments of the larynx. Consequently, the cause of death was identified as asphyxia due to manual strangulation.

Considering that micro-CT analysis is able to generate images with a high level of detail compared to conventional radiological techniques, in cases of subtle fatal neck compression this type of investigation could be useful for the morphological identification of comminuted bilateral fractures. This may be particularly useful in cases involving children and young adults where fractures or cartilage damages may be minimal or absent as a consequence of the elasticity of the ligaments around the larynx and hyoid bone as well as the early stage of ossification.

Manual Strangulation, Laryngeal Fracture, Micro-CT

H87 Challenging the Role of Autopsy — Results of a Multicenter Study to Validate Multi-Phase Postmortem CT-Angiography (MPMCTA)

Jochen Grimm, MD, JD, Rue du Bugnon 21, University Center of Legal, Medicine Lausanne, Lausanne, VD, SWITZERLAND; Axel Heinemann, MD, Legal Institute-Hamburg University, Legal Institute-Hamburg Eppendorf, Hamburg, GERMANY; Giuseppe Guglielmi, PhD, Viale Pinto, Foggia 71100, ITALY; Krzysztof Wozniak, MD, Jagiellonian University Medical College, Dept of Forensic Medicine, Grzegórzecka 16, Krakow 31-531, POLAND; Franziska Eplinius, MD, University of Zurich, Institute for Legal Medicine, Winterthurerstrasse 190/52, Zurich 8057, SWITZERLAND; Fabrice F. Dedouit, 1 Avenue Du Professeur Jean Poulhes, Toulouse Cedex 9, FRANCE; Florian Fischer, MD, Ludwig-Maximilians-University Hospital, Institute for Legal Medicine, Munich 80336, GERMANY; Guy N. Ruttly, MD, University of Leicester, Forensic Pathology Unit, Robert Kilpatrick Bldg, Leicester LE2 7LX, UNITED KINGDOM; Bruno Morgan, BS, Imaging Dept, Leicester Royal Infirmary, Leicester LE2 7LX, UNITED KINGDOM; Holger Wittig, MD, University of Basel, Institute for Legal Medicine, Basel, SWITZERLAND; Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne CH-1011, SWITZERLAND; and Silke Grabherr, PhD, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne 1011, SWITZERLAND*

After attending this presentation, attendees will better understand Postmortem Computed Tomography-Angiography (PMCTA), in particular the recently developed method of MPMCTA, applied by an international group of dedicated scientists in a large-scale multicentric study. Strengths and weaknesses of the method will be highlighted in comparison to autopsy and indications for performing MPMCTA will be proposed.

This presentation will impact the forensic science community by demonstrating the potential of the applied MPMCTA protocol to enhance postmortem evaluation of the cause of death. It provides a solid database to define indications for MPMCTA, conventional autopsy, or a combination of both. Results of previous studies are confirmed, indicating that in a variety of case categories, autopsy should no longer be considered the gold standard for postmortem diagnostics, but rather the combination of autopsy with contrast-enhanced postmortem imaging techniques like MPMCTA.

Purpose: Recently developed PMCTA greatly enhances postmortem diagnostics due to its ability to reliably discover even discrete vascular pathologies. While different technical approaches are pursued across the world, the need for validation and standardization of the method increases in order to facilitate its transition into forensic routine. With this goal, an international working group has performed a prospective multicenter study to validate previously published MPMCTA, define its indications, and evaluate its advantages and limitations, especially compared to conventional autopsy.

Method and Materials: Five hundred cases were included in this prospective multicenter study. All cases received MPMCTA followed by conventional autopsy. All CT images were read by a team of one forensic pathologist and one radiologist, both experienced in forensic imaging and blinded to autopsy results. All findings were recorded for each method and categorized by anatomical structure (bone, parenchyma, soft tissue, vascular) and importance for the forensic case (essential, useful, not important).

Results: The majority of findings were visualized with both techniques. MPMCTA was superior to autopsy at identifying skeletal and vascular lesions, where it detected a number of lesions essential to the forensic case which were not seen at autopsy. Conventional autopsy provided better information about essential soft tissue lesions and allowed distinguishing postmortem vs. antemortem vascular occlusions. Best results were obtained when combining both techniques.

Conclusion: Both MPMCTA and autopsy are able to detect potentially essential lesions not detected by the respective other method. This opens the path to defining indications for either one or the other method, or a combination. Combining both techniques increases the overall quality of postmortem diagnosis and in many cases augments diagnostic confidence regarding the cause of death. The results of this study provide researchers and practitioners with a solid data base and will help promote the transition of MPMCTA into daily routine for clinical and forensic pathologists.

Multi-Phase Postmortem CT Angiography, Forensic Radiology, TWGPAM

Pathology/Biology Section - 2015

H88 Diagnostic Values of Postmortem Computed Tomography (PMCT) and Multi-Phase Postmortem CT-Angiography (MPMCTA) in Blunt Trauma Death

*Dina A. Shokry, MD**, Kasr Alaini, Cairo 00202, EGYPT; Maged Nabil Hussien, MS, Medicolegal Authority-Ministry of Justice-Egypt, Medicolegal Authority-Zenhum-Cairo-Egypt, Cairo 002, EGYPT; Axel Heinemann, MD, Legal Institute-Hamburg University, Legal Institute-Hamburg Eppendorf, Hamburg, GERMANY; Klaus Püschel, MD, PhD, University of Hamburg, Institute of Legal Medicine, Butenfeld 34, Hamburg 22529, GERMANY; and Hermann Vogel, MD, Hamburg University, Hamburg-Eppendorf, Hamburg, GERMANY

After attending this presentation, attendees will better understand PMCT and MPMCTA in forensic practice for the diagnosis of blunt trauma.

This presentation will impact the forensic science community by explaining how PMCT and MPMCTA are effective tools in blunt trauma death diagnosis and how these techniques provide accurate data that conventional autopsy cannot obtain regarding the reconstruction of bony fractures and air detection.

Background: In the last decade, postmortem imaging techniques have gained a remarkable acceptance in the forensic field practices. They proved themselves as objective, non-invasive diagnostic tools for both external and internal body injuries. This is especially true in blunt trauma cases which are the most common injuries faced in forensic field practice. In this study, the sensitivity and specificity and accuracy of PMCT scan and MPMCTA were examined and compared with the conventional autopsy in diagnosing the major findings and the cause of death in blunt trauma cases to determine the advantages and disadvantages and to outline a framework for their ideal application in forensic cases.

Methods: This is a prospective study. Data was obtained from 50 decedents presented to the legal institute of Hamburg University with death allegedly due to blunt trauma. Each case underwent a whole body examination by CT and the MPMCTA was performed only for 15 cases. The resultant radiological findings are validated by conventional autopsy. Both autopsy and radiological findings are divided by body regions into the head and neck, thorax, abdomen and pelvis, extremities, and vascular system. They are then compared and correlated to the most common traumatic patho-anatomic findings, including soft tissue injuries (contusions and lacerations), hemorrhage, fractures, presence of free air in body cavities, and air emboli, in addition to the detection of the cause of death.

Results: The preliminary results show the low sensitivity and specificity of PMCT in detection of soft tissue injuries compared to MPMCTA and conventional autopsy, which almost have the same results. Both PMCT and MPMCTA are superior to autopsy in detection, configuring, and reconstruction of bony fractures and in detection and localization of air emboli and free air; however, the detection of hemorrhage is relatively dependent on the blood amount and the location of the bleeding source. Despite the presence of contrast-related artifacts, the MPMCTA has a higher sensitivity and specificity in identifying the source of the bleeding compared to the PMCT and conventional autopsy.

Conclusion: Together, PMCT and MPMCTA are effective tools in blunt trauma death diagnoses and are able to provide accurate data that the conventional autopsy cannot, regarding the reconstruction of bony fracture and air detection; however, with the observed contrast artifacts in MPMCTA and the low ability of PMCT alone in detection of the soft tissue injuries, the chance of these imaging techniques replacing the conventional autopsy is decreased.

PMCT, MPMCTA, Blunt Trauma

Pathology/Biology Section - 2015

H89 **Thanatology of the Vascular System and Its Influence on Postmortem Computed Tomography (PMCT) and Multi-Phase Postmortem CT-Angiography (MPMCTA)**

Coraline Egger, MD, CMU, HUG, Rue Michel-Servet 1, Genève CH - 1211, SWITZERLAND; Paul Vaucher, MSc, Institute of Legal Medicine, Rue Michel-Servet 1, 1211 Geneva 4, SWITZERLAND; Pierre Bize, MD, Dpt of Diagnostic and Interventional Radiology, Rue du Bugnon 46, Lausanne, AE, SWITZERLAND; Bruguier Christine, Ch. du Bugnon 21, Lausanne, SWITZERLAND; Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne CH-1011, SWITZERLAND; and Silke Grabherr, PhD, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne 1011, SWITZERLAND*

After attending this presentation, attendees will understand the complexity of blood distribution in postmortem imaging, especially due to collapsed vessels and the presence of gas in the vascular system. To avoid misinterpretation of PMCT images, knowledge of thanatological changes is important.

The goal of this presentation is to describe postmortem changes of the vascular system by investigating blood distribution, gas presence, and collapsed vessels on PMCT and their influence on MPMCTA.

Postmortem changes of the human body are broadly described in thanatology; however, there is little knowledge about the influence of postmortem reactions on the vascular system. Radiological non-invasive methods have opened new perspectives in exploring the inside of bodies and can contribute to the understanding of thanatology.

MPMCTA allows the detailed visualization and investigation of the vascular system. By applying this standardized technique, the quality of the postmortem exam can be significantly increased, especially concerning the detection of vascular lesions such as stenosis, malformation, or laceration of vessels; however, the presence of remaining blood can create artifacts that have to be recognized as such because they can imitate vital embolism or vascular occlusion.

In a first study, the postmortem MDCT data of 118 human bodies was studied. Cases with internal/external bleeding or corporal lesion allowing contamination with external air were excluded. Major vessels and heart cavities were systematically explored. Presence of gas was semi-quantitatively assessed by a trained radiologist.

Collapsed veins were observed in 61.9% of cases (CI95% 52.5 to 70.6), and arteries in 33.1% (CI95% 24.7 to 42.3). Vessels most often affected were for arteries: common iliac (16.1%), abdominal aorta (15.3%), and external iliac (13.6%); and, for veins: infra-renal vena cava (45.8%), common iliac (22.0%), renal (16.9%), external iliac (16.1%), and supra-renal vena cava (13.6%). Cerebral a. and v., coronary a., and subclavian v. were not affected. The presence of collapsed vessels was associated to a minor degree of alteration. Concerning the presence of gas, it has been observed that arteries and veins follow the same pattern of appearance of gas for the quantity and location.

A recently performed study describing artifacts due to remaining blood was carried out in 54 cases of MPMCTA. Essentially, this study has shown that artifacts visible in the vascular system during MPMCTA always appear in the same localizations. The main artifacts observed were first, filling defects of the cardiac cavities and pulmonary arteries and second, contrast agent layering in the coronary arteries and the right atrium. Thanks to this reproducibility and stability, it is possible to recognize those phenomena as artifacts and guarantee a proper radiological interpretation of the images.

By comparing the results of the two studies, the thanatological changes of the vascular system are the origin of the artifacts that can be recognized in PMCT and especially in MPMCTA. In order to prove this hypothesis, a future study is necessary superimposing the results of PMCT and MPMCTA on the same cases.

In postmortem imaging, collapsed vessels and gas in the vascular system are common and knowledge of thanatological changes is important in order to avoid misinterpretation. Due to postmortem changes, blood distribution is complex. These thanatological changes also influence MPMCTA; the remaining blood distribution is the reason for the presence of artifacts in the vascular system after angiography.

Thanatology/Postmortem Changes, Vascular System, PMCT

H90 Detection of Pulmonary Fat Embolism in Cases With Postmortem CT-Angiography (PMCTA) — Preliminary Results

*Maria Del Mar Lesta, MD**, Centre Universitaire Romand de Médecine Légale, 21 rue du Bugnon, Lausanne, Vaud 1011, SWITZERLAND; *Patrice Mangin, MD, PhD*, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne CH-1011, SWITZERLAND; and *Marc D. Bollmann, MD*, Centre Universitaire Romand, de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND

After attending this presentation, attendees will understand the repercussions of the realization of a PMCTA with an oily contrast liquid, particularly in cases where a pulmonary fat embolism is suspected, and a method that could be able to diagnose pulmonary fat embolism before the realization of the PMCTA.

This presentation will impact the forensic science community by serving as a key to determine the indication of a PMCTA with oily contrast liquid in the cases where a pulmonary fat embolism is suspected and could be the cause of death, if a method to diagnose this pathology is not available.

Introduction: Pulmonary fat embolism can be a cause of death in cases with trauma, during orthopedic surgery, and also in non-traumatic conditions, such as burns, pancreatitis, fatty liver, or sickle cell disease. As PMCTA becomes more widespread, it is important to determine how it affects the diagnosis of pulmonary fat embolism.

Purpose: The purposes of this study were to determine if the oily contrast liquid used in PMCTA induces artifactual pulmonary fat embolism, if such artifacts differ from non-artifactual (original) pulmonary fat embolism, and if pulmonary fat embolism can be detected and graded before PMCTA.

Material and Methods: Data acquisition for this prospective study was performed between November 2013 and December 2014. Consecutive cases of adults who received PMCTA followed by autopsy were included in this study. Cases were excluded if the state of alteration was too advanced. Pulmonary biopsies of each lung were taken before and after the PMCTA as were fragments of each lung with a twin-edged knife during the autopsy. The samples were examined under the microscope without fixation or staining and after an Oil-Red O staining. Pulmonary fat embolism was graded according to Falci et al.

Results: Original pulmonary fat embolism was diagnosed in seven cases out of 23 on biopsies performed before PMCTA, all having presented traumatic events before death or rib fractures due to resuscitation attempts. As expected, structures with the aspect of pulmonary fat embolism were present in almost all cases (21 cases out of 23) after PMCTA. The microscopic aspect of original and PMCTA-induced pulmonary fat embolism was identical. Grading of the pulmonary fat embolism according to Falci et al. depended on the quality of the biopsies.

Conclusions: PMCTA with oily contrast liquid induces artifactual pulmonary fat embolism that cannot be visually differentiated from antemortem pulmonary fat embolism; however, antemortem pulmonary fat embolism can be diagnosed with biopsies performed before PMCTA. In order to assure the diagnosis and correct grading of pulmonary fat embolism, the quality of the biopsy should be checked before PMCTA with oily contrast is performed. If it is impossible to obtain biopsies of good quality, the indication of a PMCTA must be discussed in cases where pulmonary fat embolism is suspected, particularly if it is a potential cause of death.

Pulmonary Fat Embolism, Postmortem CT Angiography, Diagnosis

Pathology/Biology Section - 2015

H91 Limitations of Multi-Phase Postmortem CT-Angiography in Cases of Fat Embolism: The Goal of Immunohistochemistry to Distinguish Between Artificial and Vital Fat Embolism

Natascha Pascale, MD, Viale Degli Aviatori, Foggia 71100, ITALY; Stefania C. Bello, MD, Ospedale Colonnello D'Avanzo, viale degli Aviatori, Foggia 71100, ITALY; Giuseppe Bertozzi, MD, Viale Degli Aviatori, 1, Foggia 71100, ITALY; Santina Cantatore, Viale degli Aviatori 1, Foggia 71100, ITALY; Gianpaolo Grilli, MD, Viale Pinto 1, Foggia 71100, ITALY; Margherita Neri, MD, PhD, University of Foggia, Dept Forensic Pathology, Viale degli Aviatori 1, Foggia 71100, ITALY; Irene Riezzo, PhD, Univ of Foggia, Osp D'Avanzo, Dept of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71100, ITALY; and Cristoforo Pomara, MD, PhD, University of Foggia, Dept Forensic Path, University of Malta, Dept of Anatomy, Faculty of Med & Surg Biomedical Sci, Foggia, Misida, Malta 71100, ITALY*

After attending this presentation, attendees will understand how a new technique has been developed for the Multi-Phase Postmortem CT-Angiography (MPMCTA) that allows the visualization of the vascular tree of the body via the use of an lipophilic contrast agent, Angiofil®; however, the contrast agent diffusion in the tissue has to be considered in terms of histological differential diagnosis in certain important pathophysiological events such as the embolism and, in particular, the fat embolism. The goal of this presentation is to underline the usefulness of the immunohistochemical approach in these cases to make a correct histological diagnosis between artifact due to the use of Angiofil® and true pathology such as fat embolism.

This presentation will impact the forensic science community by presenting the immunohistochemical study as the only means to distinguish between vital fat embolism and Angiofil® artifacts, lending certainly to the diagnosis of fat embolism as cause of death also in cases in which MPMCTA was performed. In this way, this technique can also be usefully performed in traumatic deaths and in all cases of suspicious fat embolisms.

In the context of forensic imaging, MPMCTA has developed as a new technique that allows the visualization of the vascular tree of the body. This is a standardized technique that consists in the performance of a native CT-scan (without contrast-agent injection), followed by three angiographic phases (arterial, venous, and dynamic phase). The angiographic phases consist of the perfusion of the vascular system with an oily contrast-agent mixed with paraffin oil through the accesses in the femoral artery and vein. This allows complete opacification of the vascular system, showing very small vascular lesions or abnormalities as exact sources of bleeding. The oily liquid Angiofil® is a contrast agent consisting of iodized linseed oil. To perform whole-body CTA, Angiofil® is mixed with paraffin oil. A mixture of 6% is determined as adequate to obtain an excellent opacification of the whole vascular system. This lipophilic contrast agent, Angiofil®, is easy to handle and highly radio-opaque. Because of its lipophilic abilities, it is retained intravascularly, hence it facilitates virtual segmentation of vessels and yields an enduring signal which is advantageous during repetitive investigations. As described in the literature, the oily liquids enter the venous system by passing through small arteriovenous shunts, while they arrest in the capillary microcirculation. This leads to embolization of lipophilic agent contrast in capillaries or small precapillary vessels and in this manner the Angiofil® can itself cause an "artificial" fat embolism.

The search for fat embolisms is often important because it may help determine the cause of death and it is also an important vital sign in cases of trauma. Fat embolism refers to the presence of fat droplets within the peripheral and lung microcirculation while fat embolism syndrome is a clinically relevant syndrome caused by the distribution of fat in the systemic vascular tree and characterized by clear signs and symptoms.

The study concerned 22 autopsies (MPMCTA was not performed prior) in which the fat embolism was pointed out as the cause of death and compared these with a control group of 22 autopsies in which the MPMCTA was performed prior to autopsy and in which any suspicious fat embolism was excluded and the death was related to other causes. A complete immunohistochemical study of all organs of the two groups was also performed. The immunohistochemical panel used to reveal fat embolism on the brain, lung, and kidney samples included anti-fibrinogen and anti-CD61 antibodies. The immunohistochemistry performed on the 22 cases of fat embolism revealed platelet aggregates (anti-CD61 antibody positive reaction) at the edge of fat globules and an adsorbed fibrinogen (anti-fibrinogen antibody positive reaction) layer to the interface of fat globules. In contrast, in the control group (in which the Angiofil® was injected) the results of the immunohistochemical investigations were negative for reaction of fibrinogen and platelets around the empty spaces in the blood vessels, thus providing evidence of an artificial fat embolism.

Fat Embolism, Multi-Phase Postmortem CT Angiography, Immunohistochemical Study

Pathology/Biology Section - 2015

H92 Implications of Postmortem Magnetic Resonance Imaging in Sudden Cardiac Death

Marco Di Paolo, via Roma 55, Pisa 56100, ITALY; Tommaso Guerrini, Via Roma 55, Pisa 56100, ITALY; Stefania Fornaro, MD, Via Roma 55, Pisa 56100, ITALY; Laura Roas, MD, via Roma 55, Pisa 56100, ITALY; Benedetta Guidi, MD, Via Santa Dorotea 1, Pescia, Pistoia 51017, ITALY; Giovanni Donato Aquaro, MD, Fondazione Monasterio CNR-TOSCANA, Via Moruzzi, 1, Pisa 56100, ITALY; and Ranieri Domenici, MD, University of Pisa, via Roma, Pisa 56100, ITALY*

After attending this presentation, attendees will understand the importance of the execution of a postmortem cardiac Magnetic Resonance Imaging (MRI) for the detection of cardiac alterations and as a guide for histological collection in the early stage of Arrhythmogenic Right Ventricular Cardiomyopathy/Dysplasia (ARVC/D).

This presentation will impact the forensic science community by showing that the interpretation of postmortem radiology, especially in the cardiovascular field, can help the examiner in performing the autopsy.

ARVC/D is characterized by fibro-fatty replacement of the Right Ventricular (RV) myocardium and by ventricular arrhythmias as the main clinical manifestation. It represents an important cause of sudden death in young people. A genetic inheritance can be demonstrated in at least 40%-50% of the cases.

A case of a fatal arrhythmia that occurred at home in a 25-year-old man due to an early phase of ARVC/D is reported. An autopsy was carried out in order to determine the cause of death. The execution of a cardiac MRI — performed before the examination of the heart — was crucial to point out two areas of fatty infiltration not evidenced macroscopically. Histological examination of the specimens collected under the guidance of imaging was suggestive for typical alterations of ARVC/D whereas no signs of infiltration were observed in other cardiac specimens.

Case Report: A 25-year-old male student suddenly collapsed in his apartment before sleeping at night. The event was witnessed by his girlfriend. Cardiopulmonary resuscitation initiated in a few minutes by an emergency physician was unsuccessful. The family denied any previous pathology. Family history was negative for sudden death or cardiomyopathy. A complete postmortem examination was performed 24 hours after death. External examination was insignificant. At internal examination, the pericardium was opened anteriorly revealing the enclosed heart. The great arteries were transected 3cm above the aortic and pulmonary valves, the pulmonary veins and the superior and inferior vena cava, and the heart was removed. It was normal in size and weighed 360g. Other organs were unremarkable. Blood and a full-thickness block of myocardium were retained (frozen) pending onward referral for genetic testing. After routine autopsy, the heart was suspended and fixated at room temperature with 10% buffered formaldehyde solution. After 24 hours of fixation, a cardiac MRI was performed using a 1.5T clinical scanner using a brain bird-cage multichannel coil. MRI protocol included a whole heart 3D-SSFP acquisition with the following parameters: slice thickness 1mm (interpolated to 0.5mm), NEX 1, FOV 19cm, matrix 512x512, 60° flip angle, TR/TE equal to 8.4/4.1. FSE images with the following parameters were also acquired: slice thickness 2mm, NEX 1, FOV 32cm, matrix 256x256, 90° flip angle, TR/TE equal to 840/8.1. In 3D-SSFP images, two focal areas of suspected fat infiltration were detected in the sub-tricuspidal region and in the lateral free-wall. These regions with suspected fat infiltration were also evidenced in FSE images. The heart underwent macroscopic examination: coronary vessels and main branches, examined by multiple cross sections, were normal; no atherosclerotic lesions were detected; RV wall thickness was 0.4cm. The investigation of the two areas clearly highlighted by MRI revealed small foci of fat infiltration without clear pathological significance. Full-thickness blocks of myocardium were removed for histological examination from anterior, lateral, and posterior left ventricular free wall, from ventricular septum, from RV outflow tract, and from both atria, according to the recommended guidelines for best practice. Furthermore, other samples were obtained directly from the areas indicated by the MRI (as being suggestive for fat infiltration). Specimens were embedded in paraffin and routinely processed.

The histological examination of “MRI guided” cardiac specimens, stained with haematoxylin-eosin and Masson, revealed fibrous and fatty tissue replacement that had swept inwards from the epicardial aspect to the endocardial aspect of the ventricle chamber. Myocardial disarray, lymphocytic infiltrates, and foci of contraction band necrosis were also observed. No remarkable alterations were detected in all other cardiac specimens. Postmortem toxicological analyses were negative for alcohol, drugs, and common toxicants. The cause of death was attributed to ARVC/D.

H93 Visualization of Myocardial Infarction by Postmortem Single-Organ Coronary Computed Tomography: A Feasibility Study

Matteo Polacco, MD, Largo F.Vito,1, Rome, ITALY; Vincenzo M. Grassi, MD, Catholic University, School of Medicine, Largo F. Vito 1, Rome 00168, ITALY; Antonio Oliva, MD, PhD, Largo Francesco Vito 1, Rome, ITALY; Riccardo Rossi, MD, Largo Francesco Vito 1, Rome, ITALY; and Valentino De Matteis, MD, Catholic University, School of Medicine, L.go Francesco Vito 1, Rome 00168, ITALY*

After attending this presentation, attendees will understand that radiological examination is generally considered a good complement for conventional autopsy; nevertheless, it was thought to have limited application in cardiovascular pathology.

This presentation will impact the forensic science community by demonstrating the main diagnostic findings in postmortem multi-detector coronary artery computed tomography in cases of sudden death in adults.

Introduction: Postmortem imaging is increasingly used in the forensic field in cases of natural death related to cardiovascular diseases, which represent the most common causes of death in developed countries. Whereas radiological examination is generally considered a good complement for conventional autopsy, it was thought to have limited application in cardiovascular pathology. The goal of this study was to investigate the role of postmortem multi-detector coronary artery Computed Tomography (CT) in cases of sudden death in adults.

Materials and Methods: Eleven patients that were revealed by standard autopsy procedures to be negative for macroscopic extra cardiac lethal findings were selected for the study. Later, isolated single organ Postmortem Computed Tomography Coronarography (PMCTA) using an iodinated non-ionic contrast medium was conducted in these same individuals. After computed tomography examination, all isolated hearts were carried to the forensic pathologist to undergo a conventional histology assessment.

Results: In seven of the 11 cadavers, a final diagnosis of myocardial infarction was made after a complete autopsy and histology procedures. In six of the 11 cases, PMCTA scanning of the isolated hearts confirmed the autopsy findings and showed the presence and localization of occlusions or severe stenosis as well as the extension of the myocardial hypoxic area by the extravasation of contrast medium.

Conclusion: Isolated single-organ PMCTA could be considered a valid and useful tool in combination with traditional autopsy investigation (macroscopic sections and histology) for identifying the cause of death by recognizing the presence and degree of coronary artery disease and myocardial infarction area visualization.

Postmortem TC, Myocardial Infarction, Sudden Cardiac Death

H94 “Virtopsy” Utility on Mummified Corpses: Two Italian Iconic Cold Cases

*Alessandra Pentone**, D.I.M Section of Legal Medicine, piazza Giulio cesare n.11, Bari 70124, ITALY; *Liliana Innamorato*, MD, D.I.M, sezione di Medicina Legale, piazza Giulio Cesare, 11, Bari 70124, ITALY; *Ilaria De Vitis*, Via Carducci 23, Cavallino (le) 73020, ITALY; and *Francesco Introna*, MD, Dim Sezione Di Medicina Legale, P.zza Giulio Cesare 11, Bari 70124, ITALY

After attending this presentation, attendees will understand the usefulness of Computed Tomography (CT) scan analysis, especially in very fragile corpses such as mummified corpses, through the presentation of two iconic Italian cold cases.

This presentation will impact the forensic science community by explaining whether or not spiral CT scans were important in finding out cause, time, and manner of death of bodies found in different circumstances and conditions, all of which were involved in famous media and/or Italian judicial events.

In the field of forensic medicine, the use of diagnostic imaging such as pre-autopsy CT represents an essential preliminary accessory examination for postmortem forensic assessment. Imaging techniques present the possibility of realizing a “virtual autopsy,” called “virtopsy”. Moreover the lack of the suffix “auto” underlines the objectiveness of this method that results in non-invasive, 3D, and sometimes the only possible evaluation on mummified, extensively decomposed or pre-skeletonized bodies where it is impossible to perform angio-CT scan or Magnetic Resonance Imaging (MRI). A CT scan examination cannot be considered an alternative to conventional autopsy, but rather a first useful tool in unusual cases, such as the cases described here. The goal of this study was to evaluate the role of a previous CT scan analysis performed in the forensic examination of extensively decomposed corpses. A CT scan was used in all the corpses deemed “precious,” which will certainly be at the center of a case status. Experience dictates that virtopsy should be routinely performed on precious bodies involved in complex cases, to crystallize them in “as is” condition before they undergo forensic examination, where they will be necessarily destroyed. The CT-scan will guarantee objective data available during the entire time of a trial and beyond.

Case 1: The mummified corpses of two young brothers were found in a pit of a large abandoned house in the downtown Gravina in southern Italy two years after their disappearance. At the time of the discovery, their father was in preventive detention as he was suspected of having beaten his sons to death and hidden their bodies. A CT-scan performed on the brothers prior to autopsy revealed multiple fractures of the pelvis and inferior limbs related to a fall. The subsequent autopsy and the histological examination confirmed the bone lesions previously detected and also discovered a soft peri-fracture haemorrhage residual confirming the “vitality” of these injuries. The cause of death of both children was identified as severe trauma due to falling from a height. The lack of any kind of possible voluntarily inflicted injury allowed the father be blame-free. The CT-scan examination was essential for localizing the injuries without modifying the related bone connections and was a useful guide for those who performed the forensic autopsy.

Case 2: The mummified and partially skeletonized corpse of a girl was found in the loft of a church 17 years after her disappearance. A boy belonging to a very influential family was suspected of the girl’s murder; his family and the church itself attempted to hide and confuse the truth. The CT-scan and 3D reconstruction of the girl’s remains described the interruption of the inferior cortical layer on the posterior arch of a number of ribs. During the autopsy, it was possible to identify the exact pattern of lesions as being sharp and cut injuries identified by the CT-scan results. Virtopsy alone could not replace the forensic autopsy which made it possible to detect the exact nature, number, and direction of the lesions’ patterns and manner.

Virtopsy, CT Scan, Mummified Corpses

H95 A Scream From the Past: A Multidisciplinary Approach in a Concealment of a Mummified Corpse

*Lorenzo Gitto, MD**, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Aniello Maiese*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; *Serenella Serinelli, MD*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena 336, Rome, Lazio 00169, ITALY; *Massimiliano dell'Aquila, MD*, Sapienza University, Dept of Anatomy, Histology, Forensic Medicine, & Orthopedics, Viale Regina Elena, 336, Rome, Lazio 00169, ITALY; and *Giorgio Bolino, MBBS*, Viale Regina Elena, 336, Rome 00169, ITALY

After attending this presentation, attendees will understand the necessity of a multidisciplinary approach in solving difficult forensic cases such as mummified bodies.

This presentation will impact the forensic science community by showing the methodological approach in cases in which mummified bodies are found.

Mummification is a drying of the tissues in place of liquefying putrefaction. During mummification, water evaporates from tissues, preventing bacterial putrefaction. Mummification commonly occurs in a dry environment, preferably with a moving air current; this is usually, but not exclusively, a warm place with a specific degree of environmental oxygenation. More recently, the discovery of a mummified body in a domestic environment is rare and is generally due to the subject's social isolation while alive.

An 83-year-old white male was found mummified and sealed with tape, covered by two plastic bags, and walled within a masonry ledge built inside his bedroom. The mummification process occurred in an environment characterized by the rare process of the *Anaerobiasis mummies*.

In this case, during the police investigation of an apartment in the suburbs of Rome, a silicon-sealed door on the 2nd floor was found. Upon opening the door, a messy bedroom with a silicon-sealed window was discovered. The floor was dirty, covered with white-colored dust and rubble. In one corner of the room, an abnormal protrusion in the wall was observed. Once the ledge was demolished, a dead body in a semi-supine position with the back on the floor and the legs on the wall was found inside. Two plastic bags covered the body. Once the plastic bags were removed, the body was entirely wrapped in brown adhesive tape. No microfauna near the body were observed. The apartment owner said the body was that of his father who died two years previously of cardiovascular disease. After the father's death, the son concealed the corpse in order to obtain his annuity retirement benefits.

Upon external examination, the skin showed a dry appearance with a yellow to brown color and a leathery consistency. No traumatic injuries were present on the body surfaces. Dewatering mold spores were observed on the body surface, especially on the feet.

A postmortem computed tomography scan was performed before the traditional autopsy. The 3D rendering of the Digital Imaging and Communications in Medicine (DICOM) images using the open source software Osirix® on a MacOSX® computer was produced and revealed no traumatic injuries. At the postmortem examination of the heart, significant atherosclerosis involving left anterior descending and the left circumflex coronary arteries was present. Toxicological analyses on the organ samples were negative for drugs and alcohol. At the microscopic examination of the skin of the hand, forearms, and legs, no injuries or other anomalies were observed. At the microscopic examination of the heart, strongly decomposed tissue with interstitial fibrosis and wavy fibers was observed, consistent with an acute ischemic injury. The cause of death was due to atherosclerotic cardiovascular disease and the manner of death was pronounced as natural.

A natural mummification process usually requires 6 to 12 months in adult subjects to be completed, and an environment with hot, dry, moving air is required. In this case, the body was completely mummified despite these environmental conditions not being present. As the body was completely wrapped in tape and walled in, an anaerobic environment could be inferred. Aufderheide underlines how exclusion of air would enhance preservation due to the inhibition of the putrefactive processes. At the same time, a casing that covers the corpse protects it from insects and scavengers.

Pathology/Biology Section - 2015

When a mummified body is found, the manner of death could be related to accident, suicide, homicide, and/or concealment of a corpse. On the one hand, forensic pathologists must know that a complete mummification process can occur in special environmental conditions, different from what is described in literature. On the other hand, when a mummified body is found, a multidisciplinary approach is required in order to reach the correct diagnosis. Thanks to the data concerning the crime scene, the autopsy findings, the radiological examination before the autopsy, and the histopathological and toxicological analyses, the resolution of a case can be possible even many years after the death of the subject.

Mummification, Concealment, Multidisciplinary Approach

H96 Jay Dix Memorial Bonus Day

*Michael A. Graham, MD**, Saint Louis University School of Medicine, Division of Forensic Pathology, 3556 Caroline, Rm C305, St. Louis, MO 63104; *Joseph A. Prahlow, MD**, The Medical Foundation, 530 N Lafayette Boulevard, South Bend, IN 46601; *J. Keith Pinckard, MD, PhD**, Office of the Medical Investigator, MSC07 4040, 1 University of New Mexico, Albuquerque, NM 87131-0001; *Joyce L. deJong, DO**, WMU Homer Stryker MD, School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; and *Jonathan Hayes, MD**, OCME, 520 1st Avenue, New York, NY 10016

After attending this presentation, attendees will understand how and why deaths related to the previously specified topics occur. Attendees will learn a systematic approach to the evaluation of such deaths that can easily be implemented in their daily practices.

This presentation will impact the forensic science community by presenting a comprehensive review of what causes and contributes to deaths related to the previously specific topics. Attendees will be able to systematically evaluate deaths in which the previously specified topics may have played a role that they encounter in their daily practices.

A proper medicolegal death investigation is a multidisciplinary process that often involves non-medical personnel as well as medical professionals. This annual series of lectures is intended to provide the non-forensic pathologist forensic scientist a comprehensive basic review of selected topics in forensic pathology in order to increase familiarity, understanding, and enhance inter-discipline communication.

This year's lecturers will discuss: the investigation of sharp force trauma; infant deaths; deaths temporally related to apprehension by law enforcement personnel; deaths related to sports and recreation; and, asphyxial deaths.

Case 1: Sharp force injuries are one of the major categories of mechanical injury. They result from the mechanical division of tissues by sharp or pointed objects. Sharp force injuries include stab wounds, cuts (incised wounds), and chop wounds; the latter being caused by relatively heavy edged objects such as a machete or axe. Multiple mechanisms play a role in injury and deaths involving sharp force injuries. Understanding and evaluating injuries and deaths in which sharp force injuries may have played a role requires basic knowledge of injuries caused by sharp forces and how to distinguish them from other types of trauma, recognition of patterned injuries, and recognition of injury patterns (e.g., defensive wounds, "hesitation marks"). This lecture will provide a comprehensive review of these issues.

Case 2: The death of an apparently healthy infant is a devastating event for the infant's survivors and is accorded significant attention by society. Infant death may be caused by a wide variety of diseases and injuries, involve a variety of mechanisms, and can be natural, accidental, or homicidal. External and/or internal evidence of disease or injury may be lacking. Accurate recognition of the cause, mechanism, and manner of death has important implications for the survivors, other interested investigative and health agencies, and society in general. Recognition of factors involved in sudden unexpected infant deaths can help in enhancing the safety of other family members and serve as a basis for formulating death prevention strategies. This lecture will discuss the investigation and interpretation of findings in sudden unexpected deaths involving infants.

Case 3: There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are temporally related to custody. The custody process can be divided into several stages — pre-custody, pre-incarceration, and incarceration. Particular diseases and injuries tend to occur and/or become manifest during each of these stages. This lecture will systematically review what diseases and injuries cause/contribute to death in the phases of custody related to apprehension and arrest, how they affect physiology and anatomy, when they are typically operative, and how they are manifest. Recognizing what occurs during the various stages of custody allows a systematic approach to assessing deaths that occur during the custody process. This lecture will review the conceptual and practical aspects of understanding and investigating deaths that are temporally related to the apprehension/arrest phases of custody.

Case 4: There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are temporally related to participating in and, occasionally, while being a spectator at sporting or other recreational activities. Understanding these deaths requires understanding of the physical requirements to perform particular activities, susceptibility of particular diseases to stresses associated with particular activities, effects of various chemical and/or biological agents that may be taken to enhance performance, and physical injuries associated with particular recreational activities. This lecture will provide a comprehensive review of these issues in the context of investigating deaths that occur in relation to sports/recreational events. Understanding factors that are involved in deaths occurring in these circumstances also helps in instituting appropriate safety measures to protect participants and spectators.

Pathology/Biology Section - 2015

Case 5: Human life requires the uptake and utilization of oxygen along with the release of metabolic waste. Failure of these processes leads to asphyxia. There are numerous entities — mechanical and chemical — that can cause asphyxia through a variety of mechanisms, present in a wide range of scenarios, and that can be associated with a broad range of physical findings. Proper evaluation of these deaths requires knowledge of the various entities that can cause asphyxia, mechanisms through which these agents affect physiological function, scenarios under which these deaths occur, and factors that contribute to these deaths. This lecture will comprehensively discuss the investigation of death in which asphyxia may have played a role.

Trauma, Infant Death, Asphyxial Deaths

Pathology/Biology Section - 2015

H97 Ecology of Decomposition: A Chemical and Biological Profile of the Maggot Mass

Emily Junkins, BS*, 202 Mercury Street, Honolulu, HI 96818; and David O. Carter, PhD, Chaminade University of Honolulu, Div of Natural Sciences & Math, 3140 Waialae Avenue, Honolulu, HI 96816

After attending this presentation, attendees will understand the chemical and biological factors that influence maggot mass ecology and its potential use as a forensic tool.

This presentation will impact the forensic science community by exploring a new microenvironment and establishing a more accurate and reliable method to estimate the postmortem interval based on possibly predictable characteristics of maggot masses.

Carion decomposition is largely attributed to microorganism and insect activity. These two pathways of nutrient renewal have traditionally been considered as separate mechanisms of decomposition and studied as such; however, recent research has shown that interactions between insects and microorganisms culminate in the formation of maggot masses. Yet maggot masses associated with carcass decomposition harbor a microenvironment that has not been fully analyzed. In this study, a preliminary chemical and bacterial profile of the maggot mass is provided using a swine model (*Sus scrofa domestica*). More specifically, this is the first comprehensive view into the bacterial microbiome of the maggot mass through sequencing the V4 region of the 16S rRNA gene. To provide further description of the microbiome, culture techniques were utilized to establish what constituents of this community can be easily observed in the laboratory. In doing so, the goal is to understand the ecology of the maggot mass so that it can be used to its full forensic value.

Three swine carcasses were decomposed in a tropical savanna ecosystem in Palolo Valley, Oahu, HI. Swine were killed via electrocution and placed at the site one hour postmortem. Microbial samples were collected when the maggot masses became established (74h postmortem). The maggot mass was swabbed twice daily from 74h-128h postmortem for sequencing and culture. Simultaneously, the skin was swabbed near the maggot masses for culture. Additionally, the pH, oxidation-reduction potential, and the temperature of the maggot masses were measured. Swabs for culture were immediately transferred to the laboratory and streaked onto standard nutrient agar and incubated at 22°C for isolation. Once isolated, bacterial samples were identified via Matrix-Assisted Laser Desorption/Ionization-Time of Flight (MALDI-TOF). Swabs for sequencing were transferred to the laboratory and stored at -20°C until the survey was complete, then sequenced.

The maggot masses exhibited obvious chemical trends. From 74h to 104h postmortem the pH became more alkaline (6.4±0.5 to 7.4±0.2). At 104h to 122h postmortem, the pH became more acidic, decreasing from 7.4±0.2 to 6.7±0.1. During the final day of the study, the pH regained alkalinity and rose to 7.6±0.1. Oxidation-reduction potential increased from -283milliVolts (mV) to -78mV indicating a highly reducing environment. The temperature remained relatively constant, averaging at 35.6°C within the maggot masses and generally higher than the environmental temperature averaging at 26.8°C. Microbial data will be presented but a diverse bacterial community dominated by Proteobacteria (specifically Gammaproteobacteria), Firmicutes, and Bacteroidetes is anticipated. This community is expected to change over time as decomposition progresses, putrefactive bacteria migrate, insects oviposit on the carcass, and resources become depleted.

The results show that the chemistry of the maggot mass changes during decomposition. The shift in pH is similar to previous studies and probably occurs when macromolecules are broken down into smaller amino acid constituents. As those amino acids were further broken down into inorganic compounds such as ammonia and incorporated into the environment, the maggot masses regained alkalinity, increasing the pH. This noticeable trend in the maggot mass pH has great potential as a forensic tool as a postmortem interval estimator. The oxidation-reduction potential indicated a highly reducing environment that corresponds with sulfur reduction. From this measurement, the presence of sulfur-reducing bacteria is expected, possibly verifying the assumption that phylum Proteobacteria is a part of this maggot mass community. Finally, the maggot mass temperature being higher than environmental temperature indicates that the bacterial community might include thermotrophic taxa. These data provide novel insight into the ecology of the bacterial community. More tests, specifically in different seasons and climates, are needed to verify if these trends are consistent and predictable.

H99 Factors Related to Body Temperature From Scene to Autopsy: Implications for Forensic Entomology

Michelle R. Sanford, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand the temperature variation experienced by insect larvae during death investigations. These temperature variations represent an underestimated source of variation that occurs during transport and storage of the body prior to autopsy. This information is important to the calculation of the heat energy units (Accumulated Degree Hours (ADH)) that the developing insects use to complete their developmental milestones. These milestones are used by forensic entomologists to determine insect age, Time Of Colonization (TOC), and ultimately to generate an estimate of minimum Postmortem Interval (PMI_{min}). Heat energy as measured by temperature over a lower developmental threshold can be used by the insect toward growth and developmental progression. Hence, knowledge regarding the temperature history of the developing insect larvae is critical to accurate TOC estimation.

This presentation will impact the forensic community by improving accuracy in the calculation of TOC by more accurately accounting for the temperatures experienced by the developing larvae prior to collection. One assumption often made during the calculation of ADH is that when the body is stored in the morgue cooler, the temperature is below the 50.0°F/10.0°C lower developmental threshold assumed for most flies. Thus, no growth is assumed during cooler storage; however, the data to be presented will show that there is not only an extended cooling period for the body before it drops below the threshold temperature in the cooler, but that under some circumstances the body may never drop below the lower developmental threshold for the insect larvae.

Small temperature sensors were placed with bodies during transport and storage to investigate a variety of cases involving various stages of decomposition, insect activity, scene temperatures, scene location, nearest local weather station temperature, and decedent characteristics (e.g., weight, age, primary cause of death). These factors were used to develop a preliminary regression equation to analyze the importance of these factors on the amount of time that a body may stay above 50.0°F/10.0°C before insects can be collected during autopsy. These data are regularly collected by the medical examiner's office and hold potential to be used to adjust for transport and storage temperatures during casework. Forensic entomologists are often sent specimens collected during or after autopsy from which to estimate a TOC. A better understanding of the factors affecting body cooling and temperatures when insect growth might occur during transport and storage will aid in improving the accuracy of TOC and PMI_{min} estimates.

Time of Colonization, Minimum Postmortem Interval, Accumulated Degree Hours

H101 Aging Blow Fly Pupae Using Hyperspectral Imaging: Another Tool in the Forensic Toolbox

Sasha C. Voss, PhD, Centre for Forensic Science, University of WA (M420), 35 Stirling Highway, Crawley, Perth, Western Australia 6009, AUSTRALIA; Paola A. Magni, PhD*, University of Western Australia, Centre for Forensic Science, Myers St Bldg, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA; Christian Nansen, PhD, School of Animal Biology, University of Western Australia, Crawley, AUSTRALIA; Gavin Flematti, PhD, School of Chemistry and Biochemistry, University of Western Australia, Crawley, AUSTRALIA; and Ian Dadour, PhD, University of Western Australia, Centre for Forensic Science, 35 Stirling Highway, M420, Nedlands, Western Australia 6009, AUSTRALIA

After attending this presentation, attendees will understand the effectiveness of hyperspectral imaging in aging pupae and the advantages of this technology for entomological determination of the minimum Postmortem Interval (minPMI).

This presentation will impact the forensic science community by demonstrating the potential of hyperspectral imaging as a non-invasive and reliable technology for the accurate estimation of pupal age in forensic investigations.

Forensic entomology has been a useful tool for crime scene investigators for the best part of a century in the western world. There have been numerous cases where entomology has played a crucial role in helping to work out the details of a crime or unattended death. Estimating minPMI is still one of the most fundamental questions following a death and the application of the developmental rates of insects associated with a corpse and time frames of insect succession onto decomposing remains is a common basis for such calculations in legal situations. Blow flies are the predominant taxa used to indicate minPMI as they are among the first insects colonizing remains after death. The developmental duration of blow flies and other forensically relevant insects is strongly driven by temperature; and, specimen age is determined using reference data detailing temperature-dependent developmental time frames for specific life stages encompassing egg, larval instars, pupation, and eclosion. Problematically, there are almost no established methods which allow precise estimation of the age of a specimen beyond identification of the start and end of the life stage collected. Thus, where the duration between stages is lengthy, for instance between pupal formation and adult fly eclosion, considerable error can be introduced to the minPMI estimate. Only limited external morphological indicators of the puparia are identifiable externally and there exists a preference within many legal systems for non-invasive techniques whereby evidence remains unchanged and available for review and/or supplemental analysis.

Hyperspectral imaging was employed to discriminate between subtle differences in the reflectance characteristics of pupae. Conventional imaging and spectroscopy are integrated within hyperspectral imaging systems to obtain both spatial and spectral information from an object. Hyperspectral imaging is a promising alternative technology in the field of forensic entomology as it is non-destructive, non-invasive, suitable for both live and preserved specimens, portable (not restricted to laboratory), rapid, and comparatively cheap. As such, hyperspectral imaging is fast emerging as a valuable tool in forensic investigations with a wealth of untapped potential. Reflectance-based methodologies have been used to successfully analyze a wide range of biological phenomena in arthropods (e.g., vision in honey bees and orb-webbing spiders, courtship and territorial displays among fiddler crabs). Furthermore, hyperspectral imaging has been used to identify species (e.g., tobacco budworms and corn earworms) and to age species (e.g., midges). At present, no study has reported on the use of hyperspectral imaging as a tool in forensic entomology. This work developed a predictive model for determining pupal age for two blow fly species, *Calliphora dubia* and *Chrysomya ruffifacies* (Diptera: *Calliphoridae*) at two developmental temperatures (24°C and 30°C). This was correlated with the morphological changes occurring during pupal metamorphosis. Furthermore, hyperspectral imaging was able to distinguish between different aged pupae that appear similar to the human eye. The potential of hyperspectral imaging analysis in forensic case work is extensive and will be discussed.

Hyperspectral Imaging, Blow Flies, Aging

H102 Diurnal Oviposition of Blow Flies: Does Time of Day Influence the Likelihood or Magnitude of Oviposition?

Kristi Bugajski, PhD*, 1610 Campus Drive, E, Valparaiso, IN 46385

After attending this presentation, attendees will better understand the impact that the time of day has on blow fly (Diptera: Calliphoridae) oviposition (egg laying).

This presentation will impact the forensic science community by making attendees aware that any information regarding blow fly oviposition is critical for accurate Postmortem Interval (PMI) estimations; this research provides important insights into diurnal blow fly oviposition and the abiotic factors that may be influencing it.

Many studies have been conducted on the nocturnal oviposition behavior of blow flies and most authors conclude that it does not occur. Forensic entomologists know that blow flies lay eggs diurnally, but according to this research, there have been no studies documenting differences in hourly diurnal oviposition in blow flies. Studies of other insects show two daily oviposition peaks and researchers are interested in determining whether or not blow flies exhibit a similar behavior.

This presentation has important implications for forensic science. If this research finds a diurnal time period during which oviposition does not occur, it will impact forensic entomologist's PMI estimations. The PMI is the time period between death and corpse discovery and entomologists provide an estimation of this interval based on insect activity. A long delay in oviposition during the morning hours could result in entomologist's needing to push PMI estimations back to the previous day.

This study seeks to document any differences in the likelihood or magnitude of oviposition by blow flies in relation to hours after sunrise. Research is being conducted in Valparaiso, IN, during the spring, summer, and fall months. Research commenced in June 2014 and will continue for multiple field seasons.

Chicken liver (17.5 grams) was put into an aluminum foil bowl and placed inside a foam container with vermiculite in the bottom. Three replicates were exposed to colonization every daylight hour starting one hour after sunrise and ending at the sunset hour. The liver was removed from refrigeration two hours before field exposure. The temperature of the liver prior to field placement was approximately 23°C. After one hour of field exposure, liver was removed from the field and checked for the presence of eggs. Any egg masses were weighed using an analytical balance. Eggs were reared to third larval instar maggots for identification. Light readings were taken hourly and weather data (temperature, humidity, and wind speed) were downloaded from Valparaiso University's weather station.

The preliminary results of four trials show no oviposition in the morning hours. Oviposition has been found between the hours of 1:15 p.m. and 6:15 p.m. and has occurred most often at light values between 4,000-8,000 lux. This is significantly lower than the highest light values of the day, which were around 100,000 lux. Oviposition has happened at temperatures ranging 21°C-26°C. One run yielded no oviposition, but temperatures did not get above 20°C. The warm weather flies *Phormia regina* (Meigen), *Lucilia coeruleiviridis* (Macquart), and *Lucilia sericata* (Meigen) have been identified in this study and the unseasonably cool summer in Valparaiso could be influencing their activity. Oviposition has been found after lux values peak for the day and within three hours of the highest temperature. Researchers will continue to examine light, temperature, and humidity to see whether fluctuations in these variables correlate with oviposition events.

These early results indicate a strong preference for oviposition in the afternoon hours. Blow flies were observed on the bait one hour after sunrise, but did not oviposit for seven hours after their initial activity. Any information regarding blow fly oviposition is critical for accurate PMI estimations and this research provides important insights into diurnal blow fly oviposition and the abiotic factors that may be influencing it.

Blow Fly, Diurnal Oviposition, Forensic Entomology

Pathology/Biology Section - 2015

H103 The First Use of Postmortem Microbiomes in Human Death Investigations

*Jennifer L. Pechal, PhD**, Michigan State University, 243 Natural Science Bldg, 288 Farm Lane Road, East Lansing, MI 48824; *Carl J. Schmidt, MD*, Wayne County MEO, 1300 Warren, Detroit, MI 48207; and *M. Eric Benbow, PhD*, Michigan State University, Dept of Entomology & Medical Specialties, 288 Farm Lane, East Lansing, MI 48824

After attending this presentation, attendees will understand that in recent years several research groups have recognized the potential use of postmortem microbiomes in forensic investigations. Several of these studies have demonstrated that the process of describing changes in microbial communities during the decomposition process of vertebrate remains has the potential for use in estimating the minimum Postmortem Interval (PMI_{min}) range. Specifically, these studies have employed metagenomic techniques, such as Illumina® MiSeq® and 454 pyrosequencing, to identify microorganisms present throughout the decomposition of model organisms (e.g., swine and mouse carcasses) or donated human remains placed in facilities dedicated to cadaver decomposition research; however, there has yet to be a study to survey the postmortem microbiome associated with human cadavers from real-world cases and evaluate the potential use of these bacterial communities in death scene investigations.

This presentation will impact the forensic science community by providing the first baseline database of the human postmortem bacterial communities found on human cadavers during routine death investigations of a medical examiner's office. Determination of the PMI_{min} range is a critical measure following events such as homicide or unwitnessed deaths, and resolving the precise window of time and location of both the decedent and witness(es) is essential for excluding or including witness accounts and for defining the circumstances of death. Microorganisms are ubiquitous in the environment and associated with humans both antemortem and postmortem and are often overlooked and underutilized biological indicators of circumstances and length of time since death. Little is known about this postmortem microbiology and biodiversity in human cadavers, particularly the microbial succession of indigenous microflora residing on or in the human body throughout decomposition; however, recent work suggests that bacterial communities are quite dynamic during the postmortem interval on model organisms. While there are several research groups developing predictive models based on the changes in microbial communities to estimate PMI_{min} ranges on these surrogates for human cadavers (e.g., swine and mouse), none to date have applied these statistical approaches to PMI_{min} estimates for human remains; the first step toward developing models to be used in human death investigations is to establish a baseline database of known bacterial taxa found on human cadavers resulting from various manners of death and in differing progressions of the decomposition process. The goal of this presentation is to describe the human bacterial communities on different areas of cadavers in relation to manner of death and autopsy-estimated PMIs from human remains discovered in a major metropolitan city — Detroit, MI. Here, the first baseline database of the postmortem microbiome developed from human remains investigated by a medical examiner's office is presented.

Bacterial samples were collected from human remains received into the Wayne County Medical Examiner's Office in Detroit, MI; each cadaver represented different circumstances of death and progression of decomposition. Individual DNA-free sterile cotton-tipped swabs were used to aseptically collect individual bacterial communities from six areas: the external auditory canal, nose, mouth, umbilicus, rectum, and the trabecular space between the inner and outer tables of the occipital bone. DNA extractions were performed according to the manufacturer's instructions using the Invitrogen™ PureLink® Genomic DNA Mini Kit. DNA was quantified using a Qubit® 2.0. All bacterial DNA samples were sequenced using Illumina® MiSeq® (2x250bp paired-end). Library construction and sequencing of the 16S rRNA V4 gene region was performed by the Michigan State University Genomics Core Facility using a modified version of the protocol adapted for the Illumina® HiSeq® 2000 and MiSeq®. Samples were collected from 50 cadavers representing four manners of death: homicide, suicide, accident, and natural. There were distinct bacterial community assemblages found on individuals based on body region and related to manner of death. Additionally, there was increased variation of bacterial community composition within an individual (across all sampled body regions) compared to communities among individuals.

This project greatly expands on earlier studies of the postmortem microbiome by partnering with a medical examiner's office to characterize bacterial communities associated with a large number of human cadavers during routine death investigations. These data offer a transformative way to rectify common practical issues associated with studying human decomposition while moving the science of postmortem microbial communities in a direction that addresses the importance of replication and real-world cases.

Postmortem Microbiome, Medical Examiners, PMI Estimates

Pathology/Biology Section - 2015

H104 Cadavers Show Distinctive Thanatomicrobiome Signatures

*Ismail Can**, 915 S Jackson Street, Montgomery, AL 36104; *Gulnaz T. Javan, PhD*, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; *Alexander Pozhitkov, PhD*, University of Washington, Seattle, WA 98195; and *Peter A. Noble*, Alabama State University, Montgomery, AL 36104

After attending this presentation, attendees will understand the challenges/rewards of sampling the microbiome in human cadaver samples and its potential usefulness for determining the Postmortem Interval (PMI).

This presentation will impact the forensic science community by providing detailed information regarding how to sample the microbiome in order to understand how microorganisms colonize internal organs after human host death.

One of the challenges in forensic science is estimating PMI accurately. PMI is defined as the elapsed time-since-death and it is used in civil and criminal investigations to prove or disprove testimonial evidence (e.g., insurance fraud and homicides, respectively). Although there are many methods to determine PMI, most are susceptible to a range of errors and biases due to an overall poor understanding of how human bodies decompose.

Recent advances in DNA sequencing technologies have resulted in a paradigm shift in the understanding of the microbiome in healthy and diseased humans. For instance, it is now known that 90% of the total cells in a human body are microorganisms; however, what happens to these cells when a human dies is not known. The working hypothesis is that microorganisms involved in decomposing human bodies (i.e., thanato-, Greek definition of death, microbiome) provide an accurate clock for determining the PMI.

The objectives of this study were to survey the thanatomicrobiome of internal organs (the spleen, liver, brain, heart) and blood in human cadavers using two DNA sampling methods to determine which one was optimal for future studies.

The thanatomicrobiome were sampled from human cadavers with PMIs ranging from 20 to 240 hours. Amplifying the 16S rRNA genes and sequencing the amplicons from organ tissues and the blood of five cadavers was used to determine the effectiveness of the DNA sampling methods. Pair comparisons revealed that the conventional DNA extraction method (bead-beating in phenol/chloroform/ bead-beating followed by ethanol precipitation) yielded more 16S rRNA amplicons (28 of 30 amplicons) than the second method (repeated cycles of heating/cooling followed by centrifugation to remove cellular debris) (19 of 30 amplicons). Shannon diversity index of the 16S rRNA genes revealed no significant difference by extraction method. DNA sequencing of 19 organ tissue and blood samples yielded a total of 599,268 reads with an average of 31,540 reads per sample (~500bp).

Ordination plots and hierarchical clustering of the annotated data revealed that, in general, the thanatomicrobiome was highly similar among organ tissues from the same cadaver but very different among the cadavers, possibly due to differences in the elapsed time-since-death and/or environmental factors.

H105 DNA Extraction and Sample Storage Considerations for Using Metagenomic Sequencing Approaches to Evaluate Soil Microbial Communities Associated With Human Death Scenes

Sheree J. Finley, MS, Alabama State University, 915 S Jackson Street, Montgomery, AL 36104; Jennifer L. Pechal, PhD, Michigan State University, 243 Natural Science Bldg, 288 Farm Lane Road, East Lansing, MI 48824; M. Eric Benbow, PhD, Michigan State University, Dept of Entomology & Medical Specialties, 288 Farm Lane, East Lansing, MI 48824; and Gulnaz T. Javan, PhD, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104*

After attending this presentation, attendees will understand how to collect bacterial evidence from human cadaver-associated soils using optimized DNA extraction methods, specifically testing the use of commercially available DNA extraction kits and the efficacy of short-term sample storage on the quality of genomic DNA to be used in downstream molecular applications (e.g., metagenomics).

This presentation will impact the forensic science community and practitioners interested in using bacterial communities found in soils associated with human decomposition by comparing five methods of DNA extraction. Soil, particularly cadaver-soil, provides crucial physical and forensic evidence that may be used to link a criminal to a crime scene, identify an unknown corpse, or determine if a body has been moved from its original burial location. The sensitivity and precision in Polymerase Chain Reaction (PCR) amplification of the extracted DNA is paramount for forensic lab protocols; however, complex organic and inorganic substances in soil samples make standardizing methodologies for DNA extraction difficult. Recent studies suggest there are important variations in methods that provide optimal extraction of high-quality genomic DNA for downstream molecular applications, such as PCR and next generation sequencing.

The goals of this study were to evaluate soil extraction and storage methods to determine an effective, relatively rapid, and standardized method for obtaining ample concentrations of high-quality DNA. Five DNA extraction methods were compared to assess the yield and purity of DNA from soil collected beneath five body zones of replicate human cadavers. Furthermore, the efficacy of short-term DNA storage at 6°C and in an RNA stabilization solution on DNA yields was compared between two commercial extraction kits using non-cadaver-associated soils.

The cadaver-soil samples were obtained from cadavers placed at the outdoor research facility Freeman Ranch located at the Forensic Anthropology Research Facility (FARF) at the Forensic Anthropology Center at Texas State (FACTS) University in San Marcos, TX. Samples were collected from the soil located under and juxtaposed to five body zones: the cranium, the right and left foot, and the right and the left olecranon. Four commercial soil DNA extraction kits and one lab-optimized DNA extraction method were used to extract genomic DNA (in duplicate) from each of the cadaver-soil samples. A spectrophotometer for optical density measurements was used to assess DNA yields (ng/μl) and quality; specifically, the purity of DNA extractions were evaluated by measuring the ratio of Ultraviolet (UV) absorbance at 260/280nm and 260/230nm for protein and humic acid contamination, respectively. Following quantification of DNA, each sample was tested for the presence of the desired 16S rRNA gene regions using targeted amplification by PCR. The results of the DNA extraction method comparison study revealed DNA yields of 50-107ng/μl with the purity of samples ranging from 1.59-1.93 (260/280nm) and 0.75-1.82 (260/230nm). As an additional comparison, DNA was extracted from non-cadaver soil that was preserved using either cold storage (6°C) or an RNA stabilization solution for 20 days. Non-cadaver-soil samples stored in an RNA stabilization solution had a greater mean DNA yield compared to soil samples stored at 6°C for both commercial extraction kits.

This research provides new information and specific parameters by which cadaver-soil microbial DNA can be evaluated and is important for downstream molecular applications, which could be used to improve the estimates of postmortem timelines. These results further aid in formulating standardization protocols for forensic laboratories to achieve reproducible DNA results.

H106 Does Carcass Mass Influence the Structure of Grave Soil Microbial Communities?

David O. Carter, PhD*, Chaminade University of Honolulu, Div of Natural Sciences & Math, 3140 Waiialae Avenue, Honolulu, HI 96816; Jessica L. Metcalf, PhD, Chemistry and Biochemistry, Jennie Smoly Caruthers Biotech Bldg, Boulder, CO 80309; Amnon Amir, PhD, University of Colorado Boulder, BioFrontiers Institute, 596 UCB, Boulder, CO 80309; and Rob Knight, PhD, University of Colorado, Dept of Chemistry & Biochemistry, Boulder, CO 80309

After attending this presentation, attendees will understand that decomposing carcasses of contrasting mass can have similar effects on the changes in the structure of postmortem microbial communities.

This presentation will impact the forensic science community by illustrating that changes in grave soil microbial communities associated with swine carcasses in a field setting are similar to those observed with other mammals, including humans, as well as those conducted in controlled laboratory settings.

Postmortem microbial communities are crucial and dynamic contributors to the decomposition of a corpse. The activity of these decomposer microorganisms drives many postmortem changes, such as bloating and ethanol production. The development of soil microorganisms as physical evidence requires answers to several fundamental questions about the relationships between corpses, decomposition, and microbial communities. Yet one variable has received little experimental attention: how does the corpse mass influence the structure of postmortem microbial communities?

To investigate the effect of corpse mass on the structure of postmortem microbial communities, gravesoils associated with decomposing swine (*Sus scrofa domesticus*) carcasses in a pasture near Mead, NE, were collected in the summer from one to 15 days postmortem. 16S rRNA amplicons and 18S rRNA amplicons were sequenced to characterize the bacterial and archaeal communities (100 basepair reads) and eukaryote communities (~120 basepair reads), respectively.

The decomposition of all carcasses resulted in a significant change in gravesoil bacterial and archaeal communities. These differences were characterized by a decrease in acidotrophic bacteria (Acidobacteria) and basal soil-dwelling bacteria (Planctomycetes, Verrucomicrobia), which coincided with increases in the abundance of Proteobacteria, particularly Gammaproteobacteria. Significant differences were also observed between control soil eukaryote communities and those associated with post-rupture carcasses (days 9 and 15), with the exception of the 1kg neonate carcasses, which may be due to day 15 samples failing to sequence for these samples. As seen in decomposition studies both in laboratory and field settings, Rhabditidae nematodes bloomed after rupture in the other gravesoil and completely dominated microbial eukaryotic communities at day 15.

It is concluded that regardless of carcass mass, decomposition has a significant effect on soil microbial communities, although this needs to be confirmed for microbial eukaryotic communities associated with 1kg neonates. It is recommended that the decomposition of corpses greater than 50kg should be investigated in detail to determine if trends discovered in this study's data set extend to larger decomposing subjects (i.e., are corpses greater than 50kg associated with different gravesoil microbial communities?).

The current findings are similar to those of other recent investigations into the postmortem microbiome. It is becoming clear that a predictable succession-like change in microbial communities occurs to decomposition. Importantly, this study demonstrates that carcass mass has little overall effect on the decomposer microbial community, which is similar to previous studies into the release of bioavailable chemicals into gravesoils. This research has important implications for forensic science because it suggests that a microbial clock for estimating the postmortem interval may be robust to mass of a decomposing carcass.

H107 Entomotoxicology: The Past and Where to Go Next

Abigail J. Props, BS*, 60 S Kensington Court, Lafayette, IN 47905

After attending this presentation, attendees will be aware of what research has been conducted within the field of entomotoxicology, the downside of this research, and the direction the research needs to take in the future.

This presentation will impact the forensic science community by taking a good look at the research that has been conducted thus far, the implications it gives, and how a thorough field study may change these implications.

Entomotoxicology focuses on the secession trends of blow flies and/or developmental effects and toxicology levels of the maggots feeding on the tissues. The current research within the field of entomotoxicology has been done in laboratory settings on maggots fed on treated liver or other food sources. The small amount of research accomplished with injecting pigs or rabbits with controlled substances prior to death still only focused on feeding the liver to maggots in a laboratory setting.

Laboratory research can give an idea of the possibilities of entomotoxicology, but has a few downsides. Research conducted by feeding the larvae an artificial diet does not take into account any metabolism of the controlled substances by the human prior to death.¹ Even though studies performed on tissue from deceased humans can account for metabolism of the controlled substances, it does not take into account the real-life patterns of oviposition of Diptera: *Calliphoridae* and variation of toxicology levels within the human body. Blow flies normally start oviposition at the natural orifices of the body, primarily the head region. Provided the controlled substances reach the brain, ingestion of the tissue by the maggots may affect their growth and development. The current research has focused on specific tissues like the liver. With the exception of wounds in the abdomen, the liver is not a tissue that is fed upon by maggots initially.

Field studies are vital to gaining a more complete understanding of how and if controlled substances are affecting the growth and development of blow fly larvae. Examination of toxicology levels of muscle tissue, along with major organs, will allow for a better understanding of how far into decomposition and feeding of the maggots before toxicology levels will be detected within blow fly larvae.

This presentation will examine the research that has been conducted and discuss the direction research needs to take.

H109 Validating an Equation to Estimate Postmortem Interval on Oahu, Hawaii

Christopher G. Inoue, BS*, Honolulu Department of the ME, 835 Iwilei Road, Honolulu, HI 96817; and David O. Carter, PhD, Chaminade University of Honolulu, Div of Natural Sciences & Math, 3140 Waiialae Avenue, Honolulu, HI 96816

After attending this presentation, attendees will understand a proposed universal formula for estimating Postmortem Interval (PMI), how the formula was used at actual human death scenes on Oahu, HI, and how the formula was inconsistent in providing accurate estimates of PMI.

This presentation will impact the forensic science community by providing key data from actual death scenes in a tropical climate in the pursuit of an accurate universal formula to estimate PMI.

In medicolegal death investigation, PMI can be one of the key elements of an investigation. Establishing PMI may help to identify a deceased person and corroborate witness statements. There are currently several methods to estimate PMI, including livor mortis, potassium concentration in the vitreous humor, and forensic entomology, but none of these methods both accurately calculate PMI and are universally and conveniently applied. To improve the ability to estimate PMI, a recently developed equation was implemented at ten indoor death scenes on Oahu, HI, under the jurisdiction of the City & County of Honolulu Department of the Medical Examiner.¹ The hypothesis that this equation will not be accurate in a tropical climate on Oahu because it was developed in a temperate climate on the United States mainland was tested.

In the current experiment, temperature and relative humidity data were collected at each death scene and these values, along with an estimate of soft tissue mass loss, were used to generate an estimate of PMI (days). These estimates were compared to available information about the dates that the decedents were last known alive, in order to determine the accuracy of the formula. Mean values of temperature, relative humidity, and soft tissue mass loss were compared using a *t*-test.

For five of the ten cases (50%), the estimated PMI was consistent with the known PMI. All of these cases had a known PMI of five days or less and an estimated soft tissue mass loss of 15% or less. In contrast, all of the cases in which the estimated PMI was inaccurate had known intervals ranging from four to 16 days. In four of these five cases, the estimated soft tissue mass loss was 20% or greater. Mean temperature ($P=0.82$) and relative humidity ($P=0.44$) were not significantly different between the two groups of cases (accurate vs. inaccurate); however, death scenes with accurate PMI estimates were associated with significantly ($P<0.05$) less soft tissue mass loss than death scenes with inaccurate estimates.

The current data reveal that this equation can be accurate in cases with relatively little decomposition. Like many other methods to estimate PMI, the accuracy of this equation decreased as PMI increased. The reason for this is possibly related to climate; the equation was developed in a temperate climate while the current experiment was conducted in a tropical climate. It is probable that bodies follow a different decomposition pattern in these two climates, particularly during the cooler months of the year. Although the measurements of temperature and relative humidity were instrumentally objective using a datalogger, estimates of soft tissue mass loss were more difficult due to their subjective nature. Although this equation was accurate in only 50% of these cases, it is believed that PMI estimates can be improved through the development of a standardized system to estimate soft tissue mass loss as well as an increased number of data points.

H110 Development of PowerQuant™ System: A New Robust Human and Male-Specific DNA Quantification System Which Monitors DNA Integrity

*Anupama Gopalakrisnan, PhD**, 2800 Woods Hollow Road, Madison, WI 53711; *Margaret Ewing, MSFS, Promega Corporation*, 2800 Woods Hollow Road, Madison, WI 53711; *Jonelle M. Thompson, MS*, 2800 Woods Hollow, Madison, WI; *Robert McLaren, PhD, Promega*, 2800 Woods Hollow Road, Madison, WI 53711; *Benjamin Krenke, MS*, 2800 Woods Hollow Road, Madison, WI 53711; and *Douglas R. Storts, PhD, Promega Corporation*, 2800 Woods Hollow Road, Madison, WI 53711

After attending this presentation, attendees will better understand a new robust and sensitive DNA quantification system for determining total human and male DNA content in a casework sample. Also, attendees will learn about assess DNA integrity using the PowerQuant™ System and its utility in optimized casework sample processing for downstream Short Tandem Repeat (STR) applications.

This presentation will impact the forensic science community by serving as an information tool for learning about a robust and sensitive quantitative Polymerase Chain Reaction (qPCR) assay for human DNA detection and the use of quality indices for optimized sample processing in challenging casework samples.

Current qPCR-based human DNA-specific quantification systems allow for quantification of the amount of amplifiable human and male DNA present in a sample and whether autosomal or Y-chromosomal Short Tandem Repeats (Y-STRs) are likely to be more informative based on the auto/Y quantification ratio. While this information is useful, casework samples present additional challenges such as low quantity and quality (degraded DNA and/or presence of inhibitors). Any new qPCR quantification system should therefore be sensitive, robust to inhibitors, and able to provide information on the integrity of the human DNA sample in addition to the standard human and male DNA quantification results. Due to the robust performance in the presence of inhibitors of current commercial STR systems, it is also important that any new quantification system exhibits comparable tolerance to inhibitors. To address this need, the PowerQuant™ System has been developed. This is a five-color, four-target probe based qPCR assay that simultaneously quantifies the total amount of amplifiable human DNA and human male DNA in a single assay. The multicopy targets used allow for detection down to 0.1pg/ul DNA concentrations with minimal variation in auto/Y ratios across single-source male samples. This assay also includes a new larger degradation amplicon derived from a separate region of the sample autosomal quantification target that may be used to monitor the integrity of a DNA sample. As larger amplicons tend to be more sensitive to inhibition, the internal positive control has been designed to have a similar response to inhibitors as the degradation amplicon, thereby minimizing the potential for falsely flagging inhibited samples as being degraded.

Data will be presented demonstrating sensitivity, consistency of auto/Y ratios in male DNA samples, resistance to inhibitors, ability to detect DNA degradation, species specificity, and male specificity at various ratios of male-to-female DNA.

qPCR, Degraded DNA, Inhibitor

H111 In Situ Detection of Latent DNA Using Nucleic Acid Binding Dyes and an Alternative Light Source

*Alicia M. Haines, BSc**, 16 Redlac Road, Morphett Vale, South Australia 5162, AUSTRALIA; *Shanan S. Tobe, PhD*, School of Biological Sciences, Flinders University, GPO 2100, Adelaide, South Australia 5001, AUSTRALIA; *Hilton Kobus, PhD*, Flinders University, Bedford Park, Adelaide 5001, AUSTRALIA; and *Adrian Linacre, PhD*, School of Biological Sciences, Flinders University, GPO 2100 Bedford Park, Adelaide 5001, AUSTRALIA

After attending this presentation, attendees will gain an appreciation of a method to detect latent DNA using nucleic acid binding dyes and its application in forensic science.

This presentation will impact the forensic science community by improving the collection of latent evidence by developing a presumptive test that detects DNA present at crime scenes, thus allowing a more targeted approach to swabbing for Short Tandem Repeat (STR) analysis.

DNA is deposited onto a surface by touch, yet few means have been developed for its *in situ* detection. Collecting touch DNA-type samples can be difficult as the DNA is not directly targeted, leading to many samples containing no DNA that leads to a waste of expensive reagents and kits. A range of dyes are available that bind to DNA at high specificity and the use of these dyes to detect latent DNA on various substrates and as a biological stain for forensic evidence is reported here. Six common nucleic acid-binding dyes were selected due to their increase in fluorescence in the presence of double-stranded DNA and their effectiveness in detecting latent DNA on surfaces was determined.

It has been suggested that epithelial cells are sloughed off the skin surface and can be transferred onto various substrates by touch, known as “touch DNA.”¹ It has been postulated that these cells are keratinized and lack nuclei; the DNA present on the surface is either present as a free molecule (cell-free DNA) or within a cell membrane transferred from DNA-rich sources, for example, touching the eyes, nose, and mouth.²⁻⁵ DNA contributed by any biological source of DNA, such as saliva, blood, and from touch, that cannot be seen by the naked eye refers to latent DNA. Currently, there are presumptive tests for saliva (phadebas which detects alpha-amylase), for semen (acid phosphatase, an enzyme reaction), and for blood (luminol which reacts with iron found in hemoglobin); however, none of these presumptive tests detect the latent DNA present within these biological samples.^{6,7} Currently, there are no presumptive tests for touch DNA, either.

For the detection of latent fingerprints, there are many techniques available such as powder dusting, cyanoacrylate fuming, silver nitrate, ninhydrin, indandione, and many others; however the more sensitive the technique the less applicable it is to the crime scene; items need to be taken to the laboratory for testing and often have a long reaction time.⁷ The methods applicable for crime scene testing, such as powder dusting, are not highly sensitive.⁸ Current methods for fingerprint enhancement generally work by interacting with amino acids; there are currently no methods that enhance fingerprints by detecting the DNA present.

In this experiment, common biological samples were stained with six selected dyes (GelGreen™, GelRed™, RedSafe™, SYBR® Green I, Diamond™ Dye, and EvaGreen™) to look at what was fluorescing in the samples such as hair, saliva, skin, and blood. The dyes were also applied to surfaces where latent DNA was present in fingerprints and as cell-free extracted DNA to determine the sensitivity of the dyes. The dye/DNA complex was detected using an alternative light source, the Polilight® (PL500), with an excitation wavelength of 490nm and emission through a 530nm or a 555nm interference filter.

Diamond™ dye, commonly used for gel staining, was found to be one of the more sensitive dyes and also had a longer lasting fluorescent signal that could still be detected after a month of applying the dye. This is advantageous because, if forensic evidence needs to be re-examined, then no additional dye is required to view the DNA present.

In conclusion, this study provides evidence that latent DNA can be detected with the use of nucleic acid binding dyes on substrate surfaces such as glass as a quick and sensitive method for detection. Furthermore, this research may be used to aid in development of a presumptive test for detecting latent DNA at crime scenes.

H112 Comparison of QIAcube® Differential to Manual Differential Extraction When Purified Using the QIAamp® DNA Blood Mini Kit

Kayla Holsworth, 1801½ Underwood Avenue, Huntington, WV 25701; Brittany M. Baguley, PhD, Washoe Co Sheriff's Office, Crime Lab, 911 Parr Boulevard, Reno, NV 89512; Lisa Smyth-Roam, PhD, Washoe County Sheriff's Office, 911 Parr Boulevard, Reno, NV 89512; and Pamela J. Staton, PhD, Marshall University Forensic Science MSFS & Center, 1401 Forensic Science Drive, Huntington, WV 25701*

The goal of this presentation is to provide a comparison of an automated differential wash protocol utilizing the QIAcube® and the QIAamp® DNA Blood Mini Kit protocol and a manual differential extraction procedure. These preemptive studies were needed to complete an internal validation at the Washoe County Sheriff's Office to ensure reliability of these systems and techniques for casework. Prior to placing a new method into service in a crime laboratory setting, accredited laboratories must perform internal validations according to Standard 8 of the Federal Bureau of Investigation (FBI) Quality Assurance Standards to verify that developmentally validated methods work reliably and robustly.

This presentation will impact the forensic science community by introducing studies performed to internally validate the QIAcube® automated differential wash protocol prior to purification using the QIAamp® DNA Blood Mini Kit protocol on the QIAcube®, as well as educating laboratory staff interested in exploring automated differential extraction techniques. Furthermore, the combination of the QIAcube® differential wash protocol with the QIAamp® DNA Blood Mini Kit protocol on the QIAcube® will highlight difficulties encountered when compared to other purification protocols more commonly coupled with the QIAcube® differential wash protocol.

In a 2008-2012 survey performed by the United States Department of Justice, an average of 237,868 victims reported being sexually assaulted each year, which calculates to an occurrence approximately every two minutes. Although only about half of all sexual assaults are reported, a great deal of time and effort goes into processing evidence from these cases due to the potential of samples containing female-male mixtures on which differential extractions must be performed. In forensic casework, a differential extraction is a method that incorporates the combination of phase separation with differential centrifugation to isolate sperm cells from other cell types in order to generate two distinct profiles of the victim and the assailant. Traditionally, differential extractions have been performed manually, requiring an analyst to undergo repeated pipetting and multiple centrifugation steps. Due to the hands-on nature of the approach, the quality and consistency of the separations tend to be variable from analyst to analyst. A combination of the number of sexual assault cases reported along with the time required to analyze samples from these cases has caused backlogs to become commonplace among many crime laboratories across the country. Bringing automated differential extraction procedure online would benefit analysts by not only reducing the backlog of the laboratory but also by streamlining the workflow of a lengthy process.

This study focused on determining the utility of QIAGEN's® QIAcube® for differential extraction of samples and compared it to the manual method currently being used by the Washoe County Sheriff's Office. The QIAcube®, introduced in 2007, was originally designed to extract nucleic acids and proteins and, therefore, capable of centrifuging, vortexing, pipetting, and extracting a supernatant from a pelleted sample. This study evaluated the QIAcube's® abilities, using a custom protocol, to perform differential separations on up to 12 mock sexual assault samples at a time. Experiments included a buffer study comparing three potential buffers incorporated into the lysis mixtures; a sensitivity and reproducibility study based on a 1:3 semen dilution series, with and without female epithelial cells present; a mixture study utilizing mixed female epithelial cells and semen; a cross contamination study using mixed female blood and semen; as well as a matrix and mock evidence study consisting of a mixture of female epithelial cells and semen pipetted onto different substrates along with various proficiency test samples. All studies were performed by a graduate student using a combination of four QIAcubes®. For comparison, the sensitivity and reproducibility studies were also performed by an experienced analyst. There was no sign of cross-contamination between samples, even though the tubes remain open all at the same time in the instrument. Interestingly, the manual method consistently yielded DNA concentrations approximately twice as high as the QIAcube® for the sperm fraction. Extensive troubleshooting was performed to include the use of different reagents and temperatures as well as a variety of protocol variations. In conclusion, the Washoe County Sheriff's Office will not be utilizing the QIAcube® to perform differential extractions unless future modifications of the standard protocols result in higher male yields.

Differential Extraction, QIAcube®, Troubleshooting

Pathology/Biology Section - 2015

H113 Detection of Genetic Variations in Cardiac Channelopathies Using Ion Torrent™ Next Generation Sequencing in a Cohort of Autopsy-Negative Sudden Unexplained Deaths

Audrey Farrugia, MD, PhD, 11 Rue Humann, Strasbourg, Bas Rhin 67065, FRANCE; Christine Keyser, PhD, 11 rue Humann, Strasbourg, FRANCE; Jean Muller, PhD, Laboratory Of Genetic Diagnostic, University Of Fs, 1 Place De L'hospital 67000, Strasbourg, FRANCE; Jean-Sébastien Raul, 11 Rue Humann, Strasbourg, AE 67085, FRANCE; and Bertrand P. Ludes, MD, PhD, Institut Medico-Legal, 2 place Mazas, 75012 Paris 75012, FRANCE*

After attending this presentation, attendees will better understand the considerable interest in next generation sequencing technology and the manner in which it performs a thorough genetic analysis of arrhythmogenic disorders in postmortem investigations.

This presentation will impact the forensic science community by demonstrating the implementation of a new strategy using the Ion Torrent™ Personal Genome Machine® (PGM™) System that allows the simultaneous study of the major arrhythmogenic genes in a quick and cost-efficient manner.

Background: Genetic testing for cardiac channelopathies in Sudden Unexplained Deaths (SUDs) has developed substantially over the last years. The Next-Generation Sequencing (NGS) technology provides an unprecedented opportunity to screen genetic variation underlying the arrhythmogenic genes in a short period of time at low cost. The goal of this study is to develop a strategy of systematic postmortem mutation detection on the major genes implicated in cardiac channelopathies (long QT syndrome, short QT syndrome, Brugada syndrome, and catecholaminergic polymorphic ventricular tachycardia) in order to identify the possible cause of death and to develop prevention measures for relatives.

Materials and Methods: NGS workflow based on an AmpliSeq™ panel was designed for sequencing 23 targeted genes on the Ion Torrent™ PGM™ Sequencer. The molecular analyses focused on 16 SUD cases of young people (under 35 years of age), autopsied at the Institute of Legal Medicine of Strasbourg over a period of five years. In all cases, the cause of death could not be determined after a rigorously autopsy associated with histopathological and toxicological analyses according to the guidelines of the Association for European Cardiovascular Pathology. DNA was extracted from fresh frozen tissue (heart and liver).

Results: An average of 150 variants were identified per sample; however, after the prioritization using a novel scoring program (VaRank), the number of putative variants, secondarily confirmed by sequencing, was reduced significantly. In a case of SUD that occurred during a psychiatric hospitalization, a heterozygous substitution on the *Ank2* gene, previously described as an ankyrin-B mutation associated with cardiac dysfunction, was successfully identified. Moreover, in a case of SUD that occurred during an attraction in an amusement park, a heterozygous substitution on the *Ryr2* gene, not previously described, was successfully identified, which might be damaging according to the bioinformatics prediction. Some interpretation problems encountered due to the multiplicity of identified variants were illustrated and the necessity to correlate the genetic results to the clinical data in order to identify the possible cause of death was highlighted.

Conclusion: This study illustrates that the NGS approach based on AmpliSeq™ libraries and Ion Torrent™ PGM™ sequencing may be an efficient approach integrated to the postmortem examination.

Next Generation Sequencing, Ion Torrent™, Sudden Cardiac Death

H114 Evaluation of the Ion Torrent™ PGM™ for Use With Low-Copy and Degraded Whole Mitochondrial Genome

Lisa Skandalis*, 3214 River Park Lane,S, Apt 1438, Fort Worth, TX 76116; and Kazufusa C. Okamoto, PhD, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297

After attending this presentation, attendees will understand the applications of next generation sequencing in forensic DNA analysis and, more specifically, its use with whole mitochondrial genome sequencing and human identification.

This presentation will impact the forensic science community by determining the threshold of sensitivity of the technology in the realm of human identification and to showcase the performance of Next Generation Sequencing (NGS) systems on compromised forensic samples.

The field of forensic DNA analysis, since the beginning of DNA fingerprinting assays, has continued to grow alongside newer and more sensitive technologies in the past decades. The use of NGS has found its niche among disease diagnosis/research, genetic research, genomic studies, and is beginning to delve into the world of forensics; however, this technology has yet to find its permanent place inside the forensic science toolbox as the community tends to adhere to more tested and well-used technologies that have undergone rigorous forensic optimization.

A continuing area of research in forensics is the analysis of mitochondrial DNA (mtDNA) for use with degraded or otherwise compromised samples where nuclear DNA is not present or is too damaged for Short Tandem Repeat (STR) analysis. Though the copy number may vary by tissue type, typically mtDNA is approximately 500 times more abundant than nuclear DNA; this overwhelming majority of mtDNA along with its circular form may allow for some copies to remain undamaged or whole, unlike nuclear DNA.

In many cases, the only evidence recoverable from a crime scene may be teeth, bones, or a shaft of hair, none of which may have useable nuclear DNA to generate an STR profile. Typically, the HV1 and HV2 control regions of the mitochondrial genome (mtGenome) are analyzed for human identification purposes, yet the HV1/2 regions have a lower power of discrimination compared to traditional STR methods; however, the entire mtGenome holds much more data than the HV1/2 regions alone and could offer increased intelligence in human identification. The prospect of sequencing the whole genome offers a potentially higher power of discrimination, especially when databases become more robust and more studies are performed to better understand variation within the mtGenome.

Recently, the Research, Development, Test, & Evaluation (RDT&E) laboratory at the University of North Texas-Health Science Center has developed a high-throughput protocol for mtGenome sequencing. This study evaluates the performance of the Ion Torrent™ PGM™ with whole mitochondrial DNA sequencing under three phases. The initial phase tested the mtGenome sequencing protocol at the Defense Forensic Science Center with pristine reference samples. The second phase tested the method under more stressful conditions with low-copy samples. A dilution series of DNA concentrations used in similar studies was used to determine the threshold at which “useable” analytical data can be obtained for forensic human identification purposes with the Ion Torrent™ PGM™.¹ The final phase tested the system with degraded samples that are representative of real-world evidentiary samples. Samples were enzymatically degraded to generate varying lengths of fragmented DNA. Since the mtDNA sequencing protocol begins with a long-PCR reaction requiring longer, intact DNA, the method needed to be altered. A custom RNA-capture reaction was used to preferentially enrich for mtDNA within the degraded sample in place of PCR.²

The combination of data from all three phases of this study will allow for a greater understanding of the application of this instrument and system for human identification. By testing the performance of the Ion Torrent™ PGM™ protocol with low-copy and degraded samples, forensic laboratories can begin to develop methods by which this technology can be incorporated into the field and provide the most useful data possible.

H115 Identification of Non-Synonymous SNPs in Archaeological Hair Protein: Calculation of Measures of Identity and Biogeographic Background

Jonathan Hilmer, PhD, Montana State University, Dept of Chemistry and Biochemistry, Bozeman, MT 59715; Katie Giddons, BSc, Montana State University, Dept of Chemistry and Biochemistry, Bozeman, MT 59715; Tami Leppert, MSc, University of Utah, Dept of Human Genetics, Salt Lake City, UT 84112; Brian Bothner, PhD, Montana State University, Dept of Chemistry and Biochemistry, Bozeman, MT 59715; Mark Leppert, University of Utah, Dept of Human Genetics, Salt Lake City, UT 84112; Andrew Wilson, PhD, University of Bradford, School of Life Sciences, Bradford, UNITED KINGDOM; and Glendon Parker, PhD, MS 179, 800 W University Parkway, Orem, UT 84103*

After attending this presentation, attendees will understand how proteomic datasets can be used to obtain forensic and genetic information such as quantifiable measures of identity and biogeographic background.

This presentation will impact the forensic science community by highlighting novel methods that extend the amount of genetic information which can be obtained forensically and anthropologically in the absence of usable DNA, either due to contamination or degradation.

Methodology has been developed to extract identifying genetic information from proteomic datasets. DNA typing has revolutionized forensic practice and jurisprudence; however, DNA often is degraded due to biological, chemical, or environmental factors. Protein is considerably more stable and more abundant than DNA and persists in the environment for a longer period. Protein also contains genetic information in its primary structure, the result of non-synonymous SNPs (nsSNPs) that manifest as Single Amino-Acid Polymorphisms (SAPs). These SAPs-containing peptides are accessible to shotgun tandem mass spectrometry. This study has identified nsSNP-containing peptides from 35 alleles in 26 genes expressed in the forensically informative hair shaft proteome. Complex proteomic datasets from trypsin digests of the hair shafts of 54 validated European American individuals were obtained for this study. Peptides corresponding to nsSNPs expressed in this protein population were identified and collated for each individual. The combined probability of each individual nsSNP profile was calculated using genotypic frequencies of each allelic combination in the European population (1,000 Genomes Project) and the “product-rule.” The power of genetic discrimination ranged from 1 in 1,002 to 1 in 9,000. The average power of discrimination was 1 in 280. The power of discrimination increased as a function of proteomic dataset quality ($r^2=0.624$, $n=58$, $p<0.0001$). When the power of discrimination is calculated using genotypic frequencies from the African population, increased powers of discrimination are achieved. This is consistent with a decreased likelihood that the samples originate from an African origin. Relative likelihood measurements of European compared to African genetic origin range from 1 to 780 with an average of 50, a median of 18, and a standard deviation of 116. ($n=64$). Direct validation of the imputed status of each nsSNP allele was achieved with Sanger sequencing. A total of 430 genotype determinations were made from the proteomic data and 426 assignments were confirmed (specificity=99.1%, FPR=0.93%). The overall sensitivity was 31%. Framework has been established for the use of proteomic datasets as a source of identifying genetic information, allowing measures of identity and biogeographic background to be made from forensic or anthropological protein sources, including bone, teeth, preserved soft tissue, and trace evidence such as fingerprints.

H116 A Multiplex PCR Assay for Simultaneous Analysis of 13 Rapidly Mutating Y-STRs

Rashed Alghafri, MS, 57 Light Buildings, Lumen Court, Preston, Lancashire PR1 2RA, UNITED KINGDOM; William Goodwin, PhD, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM; and Sibte Hadi, PhD, University of Central Lancashire, Fylde Road, Preston PR1 2RA, UNITED KINGDOM*

After attending this presentation, attendees will better understand the new tool that can be used in forensic DNA analysis for casework samples, specifically for sexual assault cases and population study.

This presentation will impact the forensic science community by adding a useful new tool for forensic DNA analysis.

Y-chromosome Short Tandem Repeat (Y-STR) profiling has been broadly applied in forensic casework in sexual assault cases where male/female or male/male mixtures are expected and also for population studies, genealogical research, and kinship analysis. Recently, rapidly mutating Y-STRs were described. These loci are expected to help with investigating inbred populations and also differentiating closely related males. A multiplex panel has been developed comprised of 13 Rapidly Mutating Y-STRs (RM-Yplex) that can be amplified simultaneously. The multiplex will aid investigating the human genetic structure of United Arab Emirates populations and would also be used to investigate unresolved forensic cases in the Department of Forensic Sciences and Criminology at Dubai Police.

Thirteen simultaneously amplified markers included in multiplex are: DYF387S1, DYF399S1, DYF403S1ab, DYF404S1, DYS449, DYS518, DYS526I/II, DYS547, DYS570, DYS576, DYS612, DYS626, and DYS627. Four primer sets for DYF387S1, DYS570, DYS576, and DYS612 loci have been redesigned to accommodate the loci within the multiplex using 5-dye chemistry. An allelic ladder was developed and sequenced using alleles found in United Arab Emirates populations. A developmental validation was conducted for the RM-Yplex assay to investigate the robustness of the multiplex assay including sensitivity, specificity, male/male mixtures, and male/female mixtures studies. A sensitivity study resulted in a sensitivity of the assay in amplifying as low as 62.5pg of male DNA template. In the specificity study, full male profile was detected using 1ng of male DNA template in the presence of 2,000 ng of female DNA template. A stability study using three different common inhibitors encountered in DNA profiling analysis including hematin, humic acid, and tannic acid has been demonstrated. RM-Yplex has shown great stability by resisting a concentration of 100ng/ μ l from each of hematin and humic acid, whereas it has shown more stability with tannic acid by resisting as much as 200ng/ μ l of such inhibitor. In the male/male mixture study, a complete unique minor profile has been identified successfully at 1:3 and 3:1 ratios. The RM-Yplex multiplex assay was used to amplify non-probative casework samples which gave significantly more probative information than normal autosomal amplification kits being used in DNA profiling analysis and currently used Y-STR Polymerase Chain Reaction (PCR) amplification kit results.

This study illustrates that RM-Yplex multiplex is extremely sensitive, does not exhibit cross-reactivity with female DNA, and successfully types male DNA in the presence of overwhelming amounts of female DNA. The assay was successful in typing various forensic casework samples. Thirteen RM Y-STR markers have been analyzed in 600 male samples from United Arab Emirates populations. Allelic frequencies, haplotype diversity, haplotype frequencies, and discrimination capacity were determined for the 13 RM Y-STRs. Mutations pattern analysis of the RM Y-STR loci in a typical United Arab Emirates family has been carried out and will be presented.

This research project funded by Dubai Police General Headquarters.

H117 On Combining MicroRNA Analysis With DNA STR Profiling in a Single Stream Process

Diudonné J. van der Meer, MSc, University of Huddersfield, Queensgate, Huddersfield, West-Yorkshire HD1 3DH, UNITED KINGDOM; and Graham Andrew Williams, PhD, University of Huddersfield, Queensgate, Huddersfield HD13DH, UNITED KINGDOM*

The goal of this presentation is to explain the benefits of microRNA analysis in forensic samples in order to perform body fluid identification. Newly identified controls will be demonstrated using a novel approach, combining them with DNA profiling in a single reaction. It will emphasize the opportunities arising from co-extraction of microRNAs with genomic DNA. The presentation contains state-of-the-art research that is yet largely unpublished and will update attendees on some current developments in the upcoming field of microRNA research in forensic science.

This presentation will impact the forensic science community by expanding on a novel approach where microRNA analysis is combined with DNA Short Tandem Repeat (STR) profiling to identify a human and the tissue of origin, simultaneously. New markers and controls will be revealed to work using a novel capillary electrophoresis-based approach. The presented analysis method is fully compatible with current DNA profiling workflows and allows analysis of cold-case extracts. It has the potential of becoming a versatile and cost-effective method of learning more from biological samples.

MicroRNAs have a potential to be ideal forensic markers due to their small size (~22nt), high abundance per cell, and sensitive and specific Polymerase Chain Reaction (PCR) -based detection. Thousands of microRNAs are present in biological material and they are rich in information due to their tightly regulated and cell type-specific expression. Their advantageous properties increase the chances of successful analysis from challenged crime scene samples. In addition, it has been demonstrated previously that informative microRNA expression levels can be obtained from common DNA extracts without a change in protocol and will likely be present in cold-case extracts, too.

Following an earlier pilot project on a single stream process with the integration of microRNA analysis into a DNA profiling multiplex, progress on this line of research is now presented. The small nucleolar RNAs SNORD7, SNORD44, SNORD47, and the microRNA hsa-miR-93-5p have been identified as endogenous controls. These endogenous controls have been used real-time PCR experiments — in combination with results from other research groups — to determine a larger panel of microRNAs that allow differentiation between blood, saliva, vaginal material, and mixtures thereof.

With the markers identified, the transition has been made to analysis by capillary electrophoresis. Here the analysis of the endogenous controls using capillary electrophoresis on ABI's® 3130 genetic analyzer is presented and the effects of combining their analysis with genomic DNA human identification STR markers in a single reaction are explored. The endogenous control markers are reverse transcribed using a multiplex stem-loop reverse transcription, followed by multiplex PCR with labeled primers for the cDNA and genomic DNA markers simultaneously. This approach was demonstrated before, when it was shown that blood and saliva can successfully be distinguished by amplifying hsa-miR-451a and hsa-miR-205 cDNA during DNA profiling. This will now be expanded with the newly identified endogenous controls. Future work will include the incorporation of the additional body fluid-specific markers, working toward a single reaction that can provide a DNA profile and body fluid identification on single source and mixed samples.

MicroRNA, Body Fluid Identification, Capillary Electrophoresis

H118 Postmortem Bacterial Translocation: When Does it Happen?

*Vadim Mesli, MD**, Institut Medico Legal, Rue Andre Verhaeghe, CHRU Lille, Lille Cedex, Nord 59037, FRANCE; *Erwan Le Garff, MD*, Institut Médico-légal/Forensic Institute, Rue André Verhaeghe, Lille Cedex, Nord 59037, FRANCE; *Rodrigue Dessein, PhD*, Centre de Biologie Pathologie, Bacteriologie, 2 avenue oscar lambret, CHRU Lille, Lille 59037, FRANCE; *Valéry C. Hedouin, MD, PhD*, Iml-chu Lille, Rue Andre Verraeghe, Lille 59000, FRANCE; *Christel Neut, PhD*, Laboratoire de Bactériologie Clinique, 3 rue du Professeur Laguesse, Lille 59006, FRANCE; and *Didier Gosset, MD, PhD*, Institut de Medecine Legale, Faculte de Medecine, Lille 59045, FRANCE

After attending this presentation, attendees will better understand how and when bacterial translocation occurs in a human corpse, which is one of the first microbial changes during decomposition.

This presentation will impact the forensic science community by serving as a key factor in the understanding of postmortem changes which may improve the Postmortem Interval (PMI) evaluation.

The role of human enzymes and exogenous and endogenous bacteria during the decomposition of an adult corpse is relatively poorly documented in the forensic literature. Bacterial translocation is the migration of viable bacteria from the gastrointestinal tract to extraintestinal sites, such as the blood. This phenomenon is well described for various diseases, but not from a taphonomic perspective. This study describes the epidemiology of microorganisms and bacterial translocation during human corpse decomposition.

Methods: A blood sample was taken from the subclavian area in corpses with short (less than 72 hours) and known PMI. Blood agar and enrichment cultures were performed under aerobic and anaerobic conditions, and bacterial isolation and identification were performed using phenotypic and biochemical methods and completed by the mass spectroscopic identification of anaerobic bacteria.

Results: Analyses were performed in 18 cases with a PMI between eight and 72 hours. More than 27 different bacterial strains were isolated from eight positive samples. All of the bacteria were anaerobic or facultative anaerobic bacteria, and most were known to belong to gut microbiota. No bacteria were detected from ten samples (<0.2 CFU/mL). The shortest PMI with a polymicrobial sample was four hours without including the refrigeration time (overall PMI of 27 hours). These experiments are still in process.

Discussion: As a bacterial system, a human cadaver selects microorganisms by its growth temperature. Bacterial growth is particularly influenced by anaerobic conditions rapidly after death. Proteolytic and gas-producing bacteria from the gut were identified when the PMI was short, despite the taking of samples far from the intestines. This study provides evidence that bacteria from the gut can be present and spread during the early stages of human decomposition. Under certain circumstances and depending on the cause of death, bacterial translocation could happen at different times, even during the agonal phase, following the same mechanisms as in people suffering from illnesses. A postmortem bacterial contamination also occurs later and participates in the cadaver's microbial community. Furthermore, data gained from this research may be used while interpreting results from postmortem genomic sequencing studies.

Taphonomy, Microbiology, Bacterial Translocation

Pathology/Biology Section - 2015

H119 Apoptosis in Brain Tissues: Antemortem and Postmortem Cellular Responses

*Justin C. Astin**, 780 Country Road 58, Prattville, AL 36067; *Shivani Soni, PhD*, Alabama State University, 915S Jackson Street, Montgomery, AL 36104; and *Gulnaz T. Javan, PhD*, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104

After attending this presentation, attendees will understand the intricate process of apoptosis at molecular level after death and will also gain insight into various signaling pathways and the proteins involved.

This presentation will impact the forensic science community by providing detailed information about the process of apoptosis at cellular and molecular levels postmortem and its prospective to be correlated to Postmortem Interval (PMI), which is a constant area of interest for forensic scientists.

Death is an unavoidable tragedy of life that everyone must face at some point. For forensic scientists, death is much more than just the loss of life. It is the opportunity to better understand how and perhaps even when the loss of life occurred. In terms of a criminal investigation, the determination of PMI may be the single most important task given to a forensic scientist. This determination allows the authorities to assess potential suspects. Over the years, technology has evolved to assist law enforcement agencies in the determination of PMI and although great strides have been made, there is still room for vast improvement. Cell signaling could be a key step in the right direction.

Apoptosis is commonly defined as an active, programmed, and normal physiological process of living organisms during embryogenesis and an indispensable part of eliminating damaged or unwanted cells. Although still being scrutinized, it is suggested that after the physical death of the person, cellular death, also known as apoptosis/necrosis, occurs. In simple terms, this means cellular death through apoptosis is correlated with the physical demise, which forms the rationale behind the present study.

This study will specifically target the cellular process of apoptosis related to the brain structure and function. Brain tissue has been the organ of choice for this study, with the hypothesis that being positioned far from a microbe-rich gut, decomposition will be slower in a postmortem brain. Apoptosis has two pathways that are primarily responsible to the trigger response known as the intrinsic and extrinsic pathway. The intrinsic pathway or mitochondrial pathway, as it is sometimes referred to, occurs when there are signs of cellular stress that can manifest themselves in various ways such as DNA damage or loss-of-survival factor. The second pathway, known as the extrinsic pathway, begins outside the cell, on the cellular surface. Pro-apoptotic receptors are triggered by ligands that initiate this process. Determination of the elapsed-time-since-death, more specifically PMI, is one of the biggest challenges in forensic science. After death, decomposition is activated by the process of autolysis causing cell damage, and finally directing toward cell death.

Ten brain tissues from cadaver and human healthy nerve cells from ATCC® were analyzed using human apoptotic Polymerase Chain Reaction (PCR) -array and 84 key genes were screened. The working hypothesis is: cell death is necessary for the decomposition of tissue to occur and therefore may be useful in determining the PMI. Research is underway to compare the expression profile of various pro- and anti-apoptotic proteins postmortem and antemortem from brain tissues using PCR arrays. Furthermore, the postmortem proteins expression pattern obtained will be correlated with PMI.

Apoptosis, Postmortem Interval, PCR Array

H120 Marijuana Edible Consumption as a Contributing Factor in Death: Two Cases and Live Anecdotal Accounts

Dawn B. Holmes, MD, Denver OME, 660 Bannock Street, Denver, CO 80204; Meredith A. Lann, MD, Denver OME, 660 Bannock Street, Denver, CO 80204; Billie-Jo Naysmith, BS, State of Colorado Marijuana Enforcement Division, 455 Sherman Street, Ste 390, Denver, CO 80203; Sarah Urfer, MS, ChemaTox Laboratory, Inc, 5401 Western Avenue, Boulder, CO 80301; and James Louis Caruso, MD, OME, 660 Bannock Street, Denver, CO 80204*

After attending this presentation, attendees will have a better awareness of the manifestations of marijuana edibles as a possible contributing factor in various manners of death.

This presentation will impact the forensic science community by presenting the autopsy findings and circumstances surrounding two deaths associated with marijuana edible consumption in Denver, CO. In addition, anecdotal accounts from the State of Colorado Marijuana Enforcement Division will be discussed in an effort to further understand the characteristics of this phenomenon and potential outcomes.

Introduction: As of November 6, 2012, the State of Colorado approved Amendment 64 which included legislation governing commercial manufacturing of marijuana products and retail sales. As a result, there has been an increase in recreational marijuana consumption, including marijuana edibles. Popular marijuana edibles available for purchase include cookies, candy bars, rice crispy treats, peanut butter cups, gummy bears, and various pastries. Currently, there have been two deaths in Denver, CO, where marijuana edible consumption played a contributing role to a variable degree in the cause of death.

Case 1: A 19-year-old African male and his three friends recently traveled from Wyoming to Denver, CO, for spring break and were residing in a hotel room on the 4th floor. According to his friends, the decedent consumed marijuana cookies and soon thereafter exhibited hostile behavior (pulling items off the walls) and spoke erratically. The decedent's friends attempted to calm him down and were temporarily successful; however, the decedent then reportedly jumped out of bed, went outside the hotel room, jumped over the balcony railing, and landed on the interior atrium floor. The decedent was pronounced at the scene. Autopsy findings included multiple injuries compatible with a fall from height; toxicology was positive for Delta-9 THC in the chest cavity blood.

Case 2: A 44-year-old Caucasian female contacted 911 requesting assistance as her husband was acting strangely and reportedly having hallucinations after consuming marijuana candy. The decedent repeatedly requested assistance and asked for authorities to hurry up as her husband was retrieving a gun from the safe. The 911 dispatcher heard a loud scream followed by the sound of a gunshot. Autopsy findings included a contact-range gunshot wound to the woman's head. The decedent's toxicology results were negative. The decedent's husband was arrested and is currently awaiting trial.

Discussion: Given the recent legalization of recreational marijuana use in Colorado, the resulting clinical manifestations of marijuana edible consumption are more formally becoming further elucidated. In addition to Case 1 above, anecdotal reports of post-consumption clinical symptoms have been reported by living individuals to include paranoia, suicidal ideation, and hallucinations. The possibility of these clinical symptoms playing some role as a contributing factor in a death should be considered in the appropriate forensic setting.

Marijuana, Edible, THC

Pathology/Biology Section - 2015

H121 Poor Man's Methadone: A Case Report of Loperamide Toxicity

Jennifer Dierksen*, 6431 Fannin Street, MSB 2.262, Houston, TX 77030; Morna L. Gonsoulin, MD, 1885 Old Spanish Trail, Houston, TX 77054-2098; and Jeffrey Walterscheid, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054

After attending this presentation, attendees will understand the recreational abuse of the antidiarrheal drug, loperamide (Imodium®), its mechanism of action, and the typical findings in cases of loperamide toxicity.

This presentation will impact the forensic science community by discussing the abuse of loperamide, a commonly used over-the-counter antidiarrheal drug, in order to increase awareness in the forensic and medical communities of the possible role of loperamide in cases suspicious for opioid toxicity but that have no evidence of toxic concentrations of commonly abused opioids.

The case of a 19-year-old male with a history of drug abuse who was found dead at his residence, possibly after recently attending a party, is presented. Bottles for his medications (including cyclobenzaprine, benzonatate, and nabumetone) were found at the scene, along with bottles for medications prescribed to other people. No other illicit drugs or paraphernalia were noted at the scene.

At autopsy, the major significant finding was massive urinary retention, seen frequently in opioid toxicity, with the bladder containing at least 750 milliliters of urine. Initial routine toxicology testing revealed non-toxic concentrations of alprazolam and fluoxetine as well as marijuana metabolites. Based on the strong suspicion of a drug-related death, further analysis utilizing the Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS) was requested.

The LC/TOF/MS analysis identified an unusual set of split isotope peaks, consistent with chlorine, and a molecular formula (C₂₉H₃₃ClN₂O₂) suggestive of the chemical composition of loperamide. A comparative sample of loperamide from a drugstore was analyzed by LC/TOF/MS, resulting in a mass and retention time matching the compound in the decedent's sample. Confirmatory and quantitative testing by an outside reference laboratory using gas chromatography detected 63ng/mL of loperamide, more than six times the therapeutic peak concentration. Based on these results, the cause of death was determined to be "Toxic effects of loperamide with fluoxetine and alprazolam" and the death was classified as accidental.

Loperamide (Imodium®), a synthetic phenyl piperidine opioid, is available as an Over-The-Counter (OTC) antidiarrheal medication. Like other opioids, loperamide acts in the gastrointestinal tract at mu-opioid agonist receptors, the myenteric plexi, by slowing intestinal motility. The opiate effects in the central nervous system with other opiates, such as euphoria, analgesia, and respiratory depression, are avoided with loperamide because of its decreased central nervous system penetration. Because of its decreased central nervous system effects and low abuse potential compared to other opioid drugs, loperamide was removed from Schedule V classification and can currently be dispensed without a prescription.

Loperamide is a substrate of P-glycoprotein, which causes it to be actively pumped out of the central nervous system at the blood-brain barrier; however, when P-glycoprotein is inhibited, loperamide can cross the blood-brain barrier freely and exert central nervous system effects similar to more commonly used opiates. P-glycoprotein is inhibited by many substances, including protease inhibitors, quinines, and even high doses of loperamide. Although normally poorly absorbed at therapeutic doses, loperamide ingested in massive doses can circumvent the inhibitory mechanism, remain in the central nervous system, and cause central opiate effects.

According to various sources, recreational loperamide abusers describe taking massive doses (50-200 pills) of the standard over-the-counter 2 milligram formulation, resulting in a cumulative dose of 100 to 400 milligrams. This concentration is frequently used to obtain a euphoric high, but it can be used to avoid symptoms of opiate withdrawal; for this reason, loperamide is also known as "poor man's methadone."

Loperamide toxicity in children is frequently reported to poison control centers for accidental ingestion. Most cases of adult loperamide toxicity report gastrointestinal symptoms and drowsiness with infrequent fatal outcomes. Due to its unrestricted access and low cost, loperamide abuse may be more common than the medical community realizes. Loperamide could be relatively unnoticed at a scene investigation and the drug may go undetected with routine drug screening.

Loperamide, Toxicology, Opioid Abuse

Pathology/Biology Section - 2015

H122 A Fatal Case of Reye's Syndrome Associated With Pepto-Bismol®

Sasha Osbourne, MD, Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Stephen K. Wilson, MD, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will be familiar with the etiology, pathogenesis, and potential fatal complications associated with Reye's syndrome.

This presentation will impact the forensic science community by informing attendees of how the current generation of both doctors and parents would benefit from reminders about the dangers associated with the use of all salicylate-containing compounds in children and teenagers.

A fatal case of a 7-year-old male who developed profound vomiting and loss of appetite three days after receiving an influenza A vaccination is presented. His mother gave him Pepto-Bismol® and Gatorade® as treatment and sent him to bed. He was found unresponsive less than 12 hours later and pronounced dead four minutes after arrival at the hospital. Autopsy findings included diffuse mixed micro- and macrovesicular steatosis of the liver, microvesicular steatosis in the renal tubule cells, and cerebral edema. A postmortem nasopharyngeal swab screening was positive for influenza A. Toxicology was positive for salicylate. Follow-up with the mother indicated that she was aware of the warnings against aspirin use in children and she maintained that she only gave her son Pepto-Bismol® and Gatorade®.

Reye's syndrome is a rare severe neurologic disorder consisting of a biphasic illness characterized by a viral infection followed by an acute onset of non-inflammatory encephalopathy and hepatic failure, with rapid progression to death if not properly treated. It most commonly affects children younger than 16 years of age who are treated with aspirin during certain viral infections, including varicella and influenza. The exact cause is unknown, but it is thought to result from mitochondrial impairment resulting from the actions of salicylate and its metabolites, hydroxyhippurate and gentisate. This impairment appears to be intensified during viral illnesses. The incidence of Reye's syndrome has drastically decreased since the 1980's public health campaign in the United States and Europe, which advised parents and healthcare workers of the dangers of using aspirin and other aspirin-containing products to treat children with chickenpox or influenza like illnesses. In 1986, the Food and Drug Administration mandated that all medications containing aspirin (salicylate) were required to include labels with warnings against use in children because of the potential to cause Reye's syndrome. As a result of these initiatives, the number of Reye's syndrome cases in the United States has declined from 555 cases in 1980 to approximately two cases per year currently.

This case represents the need for reiteration of the dangers of using less-familiar salicylate-containing compounds in children, especially since most young doctors and parents have had no experience with this syndrome, given its near eradication since the effective public health campaign of the 1980s.

Reye's Syndrome, Aspirin, Forensic Pathology

Pathology/Biology Section - 2015

H123 Comparison of the Concentrations of Morphine, Methadone, and Diazepam When Sampled From Cardiac, Subclavian, Femoral, and Popliteal Sites and From Clamped and Unclamped Subclavian and Femoral Vein Samples

Eric Lemaire, MD*, Medico-legal Institute University of Liège, Rue Dos-Fanchon 37, Liège, Liège B-4020, BELGIUM; and Carl J. Schmidt, MD, Wayne County MEO, 1300 Warren, Detroit, MI 48207

After attending this presentation, attendees will understand that the distance of a blood sample from the trunk has a significant impact on measured postmortem drug concentrations as does sampling technique, but to a lesser extent.

This presentation will impact the forensic science community by illustrating that popliteal blood yields lower drug concentrations than femoral blood and are probably more representative of antemortem drug concentrations. It seems that popliteal blood drug concentrations have not been previously described.

Thirty cases were sampled as follows: Right Subclavian Blood (RSCB) — dissection/clamp technique; Left Subclavian Blood (LSCB) — blindstick technique); intracardiac blood, Right Femoral Blood (RFB) — dissection/clamp technique); Left Femoral Blood (LFB) — blindstick technique); and, left and right popliteal blood. Cardiac blood was sampled in the right auricle after chest dissection. Bilateral popliteal blood was sampled after dissection and clamping of the popliteal vein because of its small caliber and localization in the popliteal fossa.

To assess Postmortem Redistribution (PMR) for each substance the mean concentrations ratios were calculated as follows: (cardiac)/(subclavian); (cardiac)/(femoral); (cardiac)/(popliteal); (subclavian)/(femoral); (subclavian)/(popliteal); and, (femoral)/(popliteal).

To compare sample techniques for each substance, mean subclavian and femoral concentrations were compared as follows: (right subclavian — dissection/clamp) — (left subclavian — blind stick) and (right femoral — dissection/clamp) — (left femoral — blind stick).

The results indicate that the popliteal sample site appears to be less subject to PMR as seen especially in the statistically significant concentrations mean ratios (femoral)/(popliteal): morphine (N=17, mean ratio=1.26, p=0.003); methadone (N=24, mean ratio=1.27, p<0.001); and, diazepam (N=14, mean ratio=1.53, p=0.012).

With regard to the differences between subclavian and femoral site sampling techniques, results show that subclavian morphine concentrations tend to be lower when drawn from a clamped subclavian vein, though this is not true for femoral sampling. Methadone and diazepam concentrations are lower when drawn from either clamped vein. For methadone, the difference is statistically significant in both femoral and subclavian sites. This means that clamping the subclavian and femoral veins and isolating them from heart blood will result in lower concentrations of drugs as shown in the in the following results: (1) subclavian blood: morphine: N=17, RSCB mean concentration=83.18, LSCB mean concentration=94.06, p=0.066; methadone: N = 24, RSCB mean concentration=1105.58, LSCB mean concentration=1370.83, p=0.0009; diazepam: N=14, RSCB mean concentration=435.21, LSCB mean concentration=503.14, p=0.079; and, (2) femoral blood: morphine: N=17, RFB mean concentration=59.47, LFB mean concentration=57.94, p=0.64; methadone: N=24, RFB mean concentration=823.42, LFB mean concentration=1042.83, p=0.037; diazepam: N=14, RFB mean concentration=416.36, LFB mean concentration=616.21, p=0.052.

This study is the first to describe popliteal blood concentrations of morphine, methadone, and diazepam and illustrates that sampling from this site results in drug concentrations lower than those in cardiac, femoral, and subclavian sampling. This means that popliteal blood is less prone to postmortem redistribution due to its distance from the trunk. This study also demonstrated that clamping a blood vessel before sampling tends to result in lower drug concentrations, even in central sites, but the results for morphine showed that there may be significant difference in the behavior of different drugs. For methadone, this concentration difference was statistically significant. It is likely that similar results with other drugs subject to postmortem redistribution will be obtained, but will require further sampling efforts.

Popliteal, Redistribution, Techniques

H124 Electrocution Deaths of United States Service Members From 2003 to 2012

Wendy S. Warren, DO*, Armed Forces Medical Examiner System, 115 Purple Heart Drive, Dover AFB, DE 19902; Lisa Rivera, DO, Armed Forces Medical Examiner System, 115 Purple Heart Drive, Dover, DE 19902; and Edward Mazuchowski II, MD, PhD, 116 Purple Heart Drive, Dover AFB, DE 19902

After attending this presentation, attendees will be aware of the injuries and epidemiological characteristics of electrocution deaths in the United States military over a ten-year period.

This presentation will impact the forensic science community by documenting the incidence of electrocution deaths within the United States military and describing the types of injuries observed with different electrical sources.

Although uncommon, deaths due to electricity occur within the United States military. An understanding of the electrical source and injuries documented at autopsy are crucial in developing tactics, techniques, and procedures to prevent future occurrences.

Methods: A retrospective review was performed by querying the Armed Forces Medical Examiner Tracking System (AFMETS) for all United States Service Member deaths that occurred under the jurisdiction of the Armed Forces Medical Examiner from 2003 to 2012 for which the cause of death was certified as electrocution. For each individual case, the following information was obtained: decedent's demographics, circumstances surrounding the incident including electrical source, physical findings/injuries observed at autopsy, and manner of death certification.

Results: Of the more than 6,500 deaths under the jurisdiction of the Armed Forces Medical Examiner during the prescribed ten-year period, there were 26 deaths of United States Service Members due to electrocution. All of the decedents were males between 19 and 33 years of age. In 13 (50%) of the cases, the individual came in direct contact with a power line. Of these 13 cases, 5 (39%) of the decedents were on the ground, 4 (31%) of the decedents were in a vehicle, 2 (15%) of the decedents were on a rooftop, and 2 (15%) of the decedents were wearing a communication radio with an antenna that came in contact with the power lines. In 6 of the 26 cases (23%), the individual came in direct contact with an electrified source due to faulty wiring. In 4 of the 26 cases (15%), the individual was working on a power source. In the remaining three cases, an individual contacted a high-voltage junction box, the rebar the individual was guiding was electrified when the crane came in contact with power lines, and an individual placed an electrical device in a bathtub. Physical findings/injuries ranged from no injuries in an individual that was in a pool with faulty wiring to decapitation and partial amputation of an extremity in an individual that contacted a power line. The manner of death in 25 of the 26 cases (96%) was certified as accident and in the case of the electrical device in the bathtub, the manner of death was certified as suicide.

Conclusion: Deaths due to electrocution in the United States military are uncommon. For those that do occur, the majority of the cases involve either contact with power lines or contact with an electrified source due to faulty wiring. In order to prevent these injuries, it is crucial to develop tactics, techniques, and procedures to eliminate or reduce the hazard. Such strategies include ensuring the proper safety procedures are followed when in the vicinity of power lines or working with electrical equipment and developing mitigating devices such as the overhead wire mitigation kit that can be placed on vehicles that may encounter low-hanging wires.

Electrocution, United States Service Member, Accidents

Pathology/Biology Section - 2015

H125 All-Terrain Vehicle and Snowmobile-Related Deaths

Melissa M. Blessing, DO, Mayo Clinic, 200 First Street, SW, Rochester, MN 55905; and Peter T. Lin, MD, 200 First Street, SW, Rochester, MN 55905*

After attending this presentation, attendees will: (1) understand the demographics of snowmobile and All-Terrain Vehicle (ATV)-related deaths; (2) appreciate common patterns of injury and toxicology findings in snowmobile and ATV-related deaths; (3) understand the various mechanisms of death encountered in snowmobile- and ATV-related deaths, including blunt force trauma and asphyxia; and, (4) have a better appreciation for the unique aspects of investigating deaths due to snowmobile- and ATV-related activities.

This presentation will impact the forensic science community by increasing awareness of the fact that snowmobile- and ATV-related deaths represent an important category of motor vehicle deaths investigated by Medical Examiner/Coroners (ME/Cs). ME/Cs should be familiar with injury patterns and common circumstances surrounding snowmobile- and ATV-related deaths, which are distinct from each other and from other motor vehicle-related deaths. Toxicology testing and interpretation are also important components of a death investigation of snowmobile- and ATV-related deaths. Detailed examination of the demographic characteristics, injury patterns, toxicology findings, and circumstances preceding injury may be helpful for implementing safety recommendations to reduce risk of injury and death.

In this study, the characteristics of ATV- and snowmobile-related deaths that occurred in southeastern Minnesota between 1999 and 2013 are described. During this time period, there were 10 snowmobile-related deaths and 16 ATV-related deaths. All snowmobile-related deaths occurred between the months of December and April, and all ATV-related deaths occurred between April and November. The average age of all deaths was 35.8 years (37.4 years for snowmobile deaths and 31.8 years to ATV-related deaths) with an overall male-to-female ratio of 7.67 (10.0 for snowmobile deaths and 4.33 for ATV-related deaths). Survival of greater than one day occurred in approximately 40% of snowmobile- and ATV-related deaths. Toxicology testing on the day of initial injury was available in 18 of the 26 deaths and showed that 66.7% of snowmobile-related deaths and 16.7% of ATV-related deaths were associated with a blood ethanol concentration above 80mg/dL. The circumstances surrounding injury could be categorized into four patterns: (1) struck a stationary object; (2) struck a moving object; (3) roll-over/ejection; and, (4) other. The percentages for circumstances of snowmobile accidents were 30% (struck a stationary object), 50% (struck a moving object), 20% (roll-over/ejection), 0% (other), and for ATV accidents 31.3%, 12.5%, 25.0% and 31.3%, respectively. The primary blunt force injury compartment (head, torso, or non-blunt force) was determined for both snowmobile- and ATV-related deaths and found to be 70%, 30%, and 0% for snowmobile-related deaths, and 62.5%, 25.0%, and 12.5% for ATV-related deaths, respectively. The “other” category for ATV-related deaths included one drowning and one compressional asphyxial death.

Snowmobile, All-Terrain Vehicle, Motor Vehicle Deaths

Pathology/Biology Section - 2015

H126 Suicides in Manitoba, Canada — A Ten-Year Study From 2003 to 2012

Thambirajah Balachandra, MBBS*, OCME, Manitoba Justice, 210 1 Wesley Avenue, Winnipeg, MB R3C 4C6, CANADA; and Muzeen Ismath, BSc*, 210-1 Wesley Avenue, Winnipeg R3P 2E3, CANADA

After attending this presentation, attendees will better understand suicides that occurred in Manitoba from 2003 to 2012, including the annual incidence of suicides, distribution by sex, locations of suicides across the province, and the presence of alcohol and drugs in confirmed suicide cases.

This presentation will impact the forensic science community by reinforcing the need to continue taking proactive measures and working with suicide prevention agencies and other health care institutions in an attempt to reduce/prevent suicidal deaths.

This was a retrospective study and involved reviewing the electronic case files of all deaths from January 1, 2003, to December 31, 2012, that were classified as suicides per this study's informational resources. The overall annual incidence of suicide was 14.28 per 100,000 population. This was higher than the national average (11.5 per 100,000).¹ The overall incidence per 100,000 population over the years ranged from 11.04 to 15.52.

There were more deaths among males (17.94 per 100,000) than in females (7.15 per 100,000). As well, the incidence of suicide was higher for rural areas (13.54 per 100,000) than for major cities (12.76 per 100,000). There are many First Nations communities throughout rural Manitoba and this could possibly explain why suicide statistics for the rural areas are higher.

From the identified cases of suicides within the ten-year study, the causes of death were found to be: hanging — 802 (50.2%); gunshot wounds — 245 (15.3%); drug overdose — 285 (17.8%); carbon monoxide poisoning — 66 (4.1%); and, other means — 200 (12.5%). The most common method of suicide was hanging. The low number of deaths due to firearms may be due to the low number of firearms in Canada. There were no deaths due to insecticide, pesticide, or weedicide poisoning during this ten-year period. This was due to the strict controls imposed on the use and distribution of these substances in Canada. In less-developed countries, the incidence of suicide due to insecticide poisoning is very high and is estimated to account for 30% of suicides worldwide.²

In 2012, there were 169 suicides; toxicology was performed in 158 of the cases (93%). Of those tested, drugs and/or alcohol were found in 135 cases. Death was due to drug overdose in 28 of these cases; however, only four cases had blood alcohol levels of greater than 80mg/100ml. In the remaining 107 cases, where death was due to causes other than drug overdose, 42 cases had blood alcohol levels of more than 80mg/100ml. Therefore, the prevalence of alcohol and drugs is common in cases of suicide in Manitoba; however, deaths actually due to alcohol and/or drugs are low.

In conclusion, although not all suicides are preventable, any effort taken to prevent even one death from occurring is worthwhile. Other jurisdictions are encouraged to compare their figures with the results of this study and to work with their local agencies and health care programs in suicide prevention.

H127 Epidemiology of Suicide in Denver

*Kelly Kobylanski, DO**, 2495 S St Paul Street, Denver, CO 80210; *Dawn B. Holmes, MD, Denver OME*, 660 Bannock Street, Denver, CO 80204; *Meredith A. Lann, MD, Denver OME*, 660 Bannock Street, Denver, CO 80204; and *James Louis Caruso, MD, OME*, 660 Bannock Street, Denver, CO 80204

The goal of this presentation is to provide data of epidemiologic significance regarding suicides in Denver, CO.

This presentation will impact the forensic science community by providing valuable information concerning an up-to-date and detailed analysis of suicide deaths in a large United States jurisdiction over a 14-year period.

This presentation consists of a retrospective analysis of all deaths categorized with a manner of suicide which occurred in the city and county of Denver, CO, from January 1, 2000, through April 8, 2014. Suicide is defined as death caused by self-directed injurious behavior with any intent to die as a result of the behavior. Suicide is the second-leading cause of death among children, teenagers, and young adults in Colorado, second only to motor vehicle traffic-related accidents. It is the leading cause of death by injury for Coloradoans ages 35-74 years old (Colorado Violent Death Reporting System, 2007). Colorado has one of the highest suicide rates in the country. Of note, the suicide rate in Denver is approximately equal to the overall state rate.

It is believed this is the first epidemiologic presentation of data for suicide deaths in Denver. With investigator assistance, an in-house database query was performed for all deaths categorized as suicidal in manner, resulting in a total of 1,293 cases collected. The data from cases was compiled into a spreadsheet. Suicide deaths were analyzed given categories available within the database, allowing for comparison of age, race, gender, marital status, method used, possible contribution of ethanol and/or other substances, settings, and time of day of the incident. In this presentation, an in-depth discussion about age distribution is included within each method of suicide, providing a comparison of method of suicide and how the method may have varied over the time period examined. How method varies with race is also discussed. Suicide deaths revealed an upward trend, noting that 2012 had a total of 109 deaths categorized as suicide, the highest number of suicides from 2003-2012. In this presentation, how a person may have one or more risk factors that would put him or her at increased risk for completing a suicide is explored. In 2009, the Denver Office of the Medical Examiner/Coroner became more aggressive in tracking these risk factors. The deaths were recorded in a way that could be better analyzed for identifiable trends to include risk over time. Potential points for further research will be discussed.

This presentation will supply valuable information to the forensic community as it provides an up-to-date and detailed analysis of suicide deaths in a large United States urban population over a significant period of time. This presentation will provide data for further comparison within any notable trends in the upcoming years, and hopefully generate discussion among forensic professionals as to how the city and county of Denver compares to other large urban populations and nationwide statistics.

Suicide, Epidemiology, Urban

H128 Fentanyl-Laced Heroin: A Maryland Public Health Problem

Natasha L. Grandhi, MD*, OCME, 900 W Baltimore Street, Baltimore, MD 21223; Rebecca Jufer Phipps, PhD, State of MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223; Mary G. Ripple, MD, 900 W Baltimore Street, Baltimore, MD 21223; Suzanne Doyon, MD, 202 Arch Street, Baltimore, MD 21201; and David R. Fowler, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223

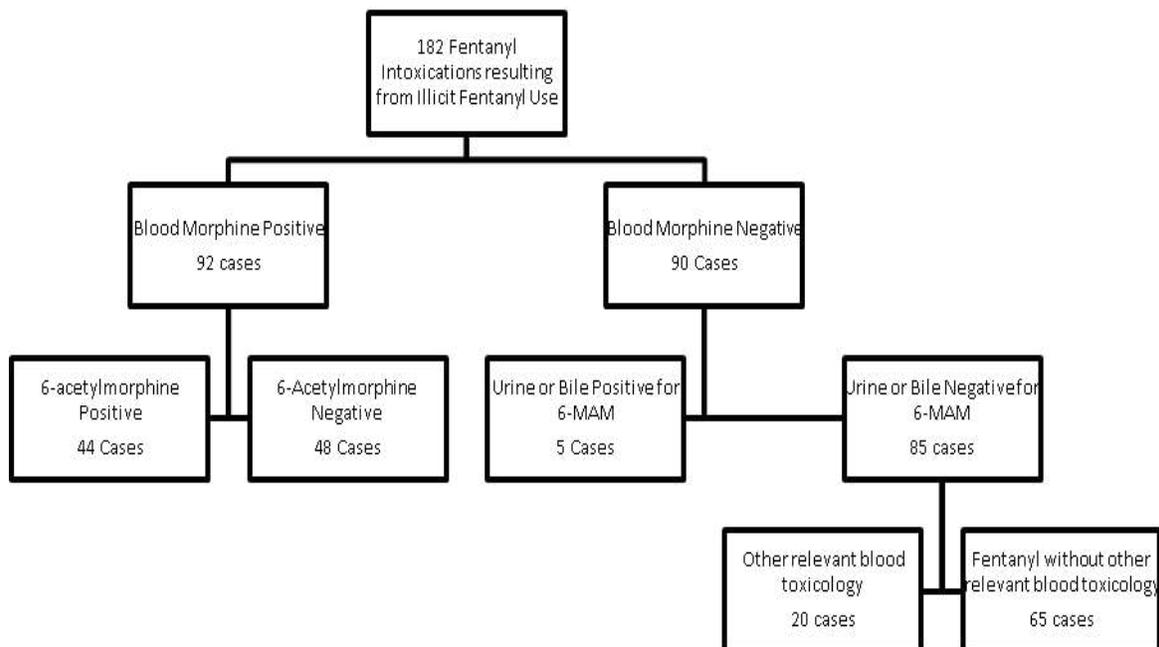

After attending this presentation, attendees will understand the importance and prevalence of synthetic drug combinations and their public health significance.

This presentation will impact the forensic science community by increasing awareness of newly emerging drug combinations and the role of the medical examiner in public health surveillance.

In January of 2014, the Office of the Chief Medical Examiner (OCME) reported that 37 Marylanders had died since September 2013 from fentanyl-laced heroin overdoses. The deaths accounted for 12% of the 318 total overdose deaths in that period. Since then, the cases have markedly increased. Nationally, there has been an increase in the number of deaths from substances variably mixed with fentanyl. In this presentation, deaths related to heroin mixed with fentanyl will be the focus. These deaths raise concerns because fentanyl is 30 to 50 times more potent than heroin and can reach the brain within minutes. Most of the users probably think that they are using just heroin and inject or snort the same amount as usual, but with deadly consequences.

A retrospective analysis of deaths investigated by the OCME from July 2012 through June 2014 (two years) was conducted. A search for cases with “fentanyl” in the Cause of Death field of the death certificate was performed. These cases were then reviewed and any case where fentanyl intoxication was not the cause of death, or those involving the abuse or use of prescription fentanyl, was excluded. This resulted in 182 cases for analysis. The cases were divided into groups based on the presence or absence of morphine and/or other drugs of toxicological significance. Ethanol was not considered for this grouping, as its presence was considered to be contributory rather than a primary intoxicant. This study identified an upward trend. There was an approximate six-fold increase in the number of deaths due to fentanyl.

The distribution of the cases is displayed below. Twenty cases had both fentanyl and quinine present with no other significant substances identified.

Pathology/Biology Section - 2015

Overall, there did not appear to be consistency in the amount of fentanyl in the mixtures with postmortem blood fentanyl concentrations ranging from 3.0ng/mL to 380ng/mL. Most victims were from Baltimore City but other counties throughout the state were also affected. Areas along the Interstate 95 corridor, including Pennsylvania, Massachusetts, Connecticut, and Rhode Island, as well as states as far away as Washington, have also reported similar deaths. The source of the fentanyl is uncertain, however recent Drug Enforcement Agency (DEA) reports indicate that the majority of fentanyl-laced heroin is being illicitly produced in Columbia and shipped to Mexico and then smuggled into the United States. Reasoning behind the use of fentanyl may include: making money for the drug cartels and dealers; persons with addictions using it to ease the pain of withdrawal; or, as a more powerful drug to chase the ultimate high.

This deadly drug trend raises serious public health concerns. Primarily as a result of this trend, the OCME has instituted automatic monthly toxicology data dumps to the Maryland Department of Health and Mental Hygiene and to the DEA. Alerting the public can be a two-edged sword, either encouraging use or saving lives. The Health Department chose to err on the side of saving lives. Alerts have gone out to the press, hospitals, and drug-counseling agencies. If dealers realize that they are killing off their customers, maybe it will not seem as cost-effective for them anymore. The jury is still out on the implications. Emergency departments should also be aware because the urine screen could be negative yet the patients look like they are suffering from heroin overdoses. Hospital staff could then counsel the patients, suggest bystander administered naloxone, analyze the doses of the drugs, or suggest other preventive measures. This presentation will summarize the case findings over the last few years, suggest public health surveillance methods, and include a review of the current literature.

Heroin, Fentanyl, Public Health

H129 Triangulating Time-of-Death With CT Scan, Immunohistochemistry, and Autopsy: An Experimental Study on Murder Case Investigations

*Alessandro di Luca, MD**, Viale Regina Elena, 336, Rome 00161, ITALY; *Alessandro Mariani, Viale Regina Elena 336, Rome 00161, ITALY*; *Valeria Panebianco, MD, Viale Regina Elena 336, Rome 00161, ITALY*; and *Luigi Cipolloni, MD, PhD, Viale Regina Elena, 336, Rome 00161, ITALY*

After attending this presentation, attendees will understand how forensic methodology on estimation of time-of-death can be implemented with new technologies and how a correct procedure may solve a case in less than 24 hours.

This presentation will impact the forensic science community by presenting a multidisciplinary approach (forensic pathology, forensic radiology, and forensic histopathology) to the everlasting problem of the chronological assessment of a murder case.

This study presents an unusual murder case where the classic measurements to determine the chronological estimation of death did not agree with the Computed Tomography (CT) scan made of the victim's body. In this case, the use of a CT scan was crucial for the exact estimation of time of death which was a new use of this technology in the forensic examination. The autopsy led to the identification of the murder weapon, thus narrowing the list of suspects and leading to an arrest and a confession by the murderer. Additionally, the immunohistochemistry confirmed a suggested hypothesis that matched the murderer's confession. In this specific case, a discrepancy was detected between the time of the reported attacker's crime and the body temperature of the discovered corpse. In fact, according to these reports, the crime would have to have been accomplished later than suspected and at a time when the suspect was seen in another place. The examination of CT images acquired before the autopsy was performed made it possible to highlight a hemorrhage in the cerebral ventricles that appeared organized, making it possible to chronologically characterize the hemorrhage and determine the time of death. Immunohistochemical staining on skin lesions was also performed to verify the viability and, where possible, the time of production. The comparison between the state of the cerebral hemorrhage and vital reactions, highlighted by immunohistochemical investigations, made it possible to demonstrate that the lesions were produced in a period preceding the time of death determined by traditional forensic thanatology phenomena. The condition of the cerebral hemorrhage and the evolution of the inflammatory phenomena shown by immunohistochemistry allowed tracing the injuries to before the time indicated by the state of rigor mortis and rectal temperature. This data established that the dating of the injuries (and thus the attack) was made at a time when the suspect did not have an alibi. Thanks to the examination of these images and immunohistochemical preparations, it was possible to assume that the victim had not died immediately after the attack but had remained in agony for many hours. This justified the discrepancy between the body temperature at the time of examination and the actual time of the assault. This case shows the possibility of using the forensic radiology, possibly together with the immunohistochemical reactions, to evaluate the state of the injuries and the determination of the time of death.

In conclusion, this study clarifies how the support of a multidisciplinary approach to murder cases, using all the tools available to the forensic examiner, are crucial for a correct legal and medical methodology and, of course, the arrest of criminal suspects.

Time-of-Death Estimation, Immunohistochemistry, CT Scan

Pathology/Biology Section - 2015

H130 Is It Proper to Cite Mitral Valve Prolapse (MVP) as the Cause of Sudden Cardiac Death (SCD)?

*Francesco Pontoriero, DO**, Rutgers-Robert Wood Johnson Medical School, One Robert Wood Johnson Place, New Brunswick, NJ 08903; and *Abraham T. Philip, MD*, Regional MEO, 325 Norfolk Street, Newark, NJ 07103

After attending this presentation, attendees will be armed with the required information when dealing with skeptical clinicians who do not accept the opinion that SCD due to MVP is a proper cause of death.

This presentation will impact the forensic science community by raising awareness about the appropriateness of the diagnosis of SCD due to MVP. This presentation will also correct the impression among clinical colleagues in whose opinion patients with MVP only succumb to the disease after developing multiple secondary complications of Congestive Heart Failure (CHF). An index case and the response from the decedent's treating cardiologist are described. This response provoked a ten-year review of SCD cases that were determined to be due to MVP.

The deceased was a 43-year-old man with a past medical history of myocarditis, diagnosed approximately a year prior to the terminal event. He was evaluated by a cardiologist who also diagnosed him with mild mitral valve regurgitation and mitral valve thickening. Terminally, he complained of headache, rapidly developed chest pain, and anoxic-type seizures. He was transported to a hospital in asystole and was pronounced dead after failure of resuscitation.

The autopsy revealed a well-nourished and well-developed man with a body mass index of 24.7kg/m². The external examination revealed no significant physical trauma and was otherwise essentially unremarkable. Internally, there was concentric biventricular myocardial hypertrophy; the heart weight was 549 grams (average heart weight for body weight 371 grams, with a range between 281 and 489 grams). There was generalized mild (less than 25%) atherosclerotic stenosis of the proximal aspect of all major epicardial arteries. There were no changes of acute, subacute, or remote myocardial infarct or significant myocarditis. The mitral valve revealed marked redundancy and, when viewed from the left atrium, looked like what has been classically described as a deployed parachute. The circumferential measurement of the mitral valve was 13.5cm. The anterior leaflet of the mitral valve measured 4cm in length with a thickness of 0.3cm. The mitral valve annulus revealed focal calcification. The chordae tendinae of the mitral valve were thickened. The other cardiac valves were unremarkable. There was pulmonary edema (combined lung weight 1,095 grams) and changes of passive venous congestion. The remainder of the autopsy was essentially unremarkable. The toxicology screen was negative. The evaluation of the conduction system was non-contributory.

The cause of death of this decedent was listed as sudden cardiac arrhythmia secondary to mitral valve prolapse. This opinion was challenged by the decedent's treating consultant cardiologist, in whose opinion, "No one dies suddenly of MVP."

A ten-year look back of cases certified as related to mitral valve prolapse was performed. Fifteen cases, aged between 25 and 62 years (mean 46 years) which included 8 males and 7 females, predominantly Caucasians (ten), few (four) of African descent, and a rare (one) Asian descent were identified. The decedents had varied clinical histories with five cases having no history of medication use or illicit drug abuse. Among the rest, there was one case each with histories of alcohol abuse, warfarin and loratadine use, cocaine abuse, fluconazole and valaciclovir use, escitalopram and metformin use, acetaminophen/oxycodone use/abuse, and the last decedent had a history of the use of tadalafil. Adequate information was unavailable in two cases. None of the decedents had a prior history of cardiac dysrhythmia.

Anatomically, the mitral valve consists of the mitral valve annulus, the anterior and posterior leaflets, chordae tendinae, and the papillary muscles. Histologically, the mitral valve consists of the fibrosa, spongiosa, and atrialis layers. The spongiosa is made up of connective tissue, proteoglycans, and some elastic fibers, all being most prominent at the free edge of the valve. The spongiosa is the major load-bearing layer of the valve and is where one sees the myxomatous degeneration due to accumulation of glycosaminoglycan (dermatan sulfate). This accumulation secondarily attenuates the fibrosa and atrialis layers leading to the "parachuting" that is classically seen in MVP.

Chesler, et al, found that MVP induced endocardial friction lesions with thrombotic lesions at the angle formed by posterior leaflet of the valve and left atrial wall could lead to fatal cardiac dysrhythmias.¹

H132 Sudden Death Due to Undiagnosed Rheumatic Heart Disease in a Child

*Pauline Saint-Martin, MD, PhD**, Service de Medecine Legale, Hopital Trousseau, CHRU Tours, Tours 37000, FRANCE; *Camille Rerolle, MD, Service de Medecine Legale, Hopital Trousseau, CHRU Tours, Tours 37000, FRANCE; Maxime Faisant, MD, Service de Médecine Légale, Hôpital Trousseau, Tours, Centre 37044, FRANCE; and Thierry Lefrancq, MD, Le Vauban, BP 549, 16 rue Clerget, Nevers 58009, FRANCE*

After attending this presentation, attendees will better understand an unusual presentation of rheumatic heart disease which may lead to sudden death in young people and, in particular, the histology of heart lesions typically caused by this disease.

This presentation will impact the forensic science community by presenting an uncommon cause of sudden death in childhood and describing how forensic scientists should recognize the signs which can lead to this diagnosis.

Introduction: Sudden death in childhood is rare. The case of a young boy who died from complications of rheumatic heart disease with atypical presentation is presented.

Case report: A five-year-old Caucasian boy was pronounced dead at his home by paramedics. He had a recent medical history that had started one month prior to death with symptoms of gastroenteritis. Twelve days before death he suffered a painless, discrete cutaneous rash on the legs and one hand; scabies was suspected and he was treated accordingly. The following day there was fever and bilateral, diffuse thigh pain. Eight days before death he had trouble walking, handling a pen, and exhibited general psychomotor retardation. He was hospitalized for seven days for evaluation of the neurological symptoms. No explanation was found and all exams were normal, although there was an inflammatory syndrome and the brain Magnetic Resonance Imaging (MRI) showed what seemed to be signal abnormalities in the left centrum semiovale. All symptoms had disappeared during hospitalization and the boy was feeling well, so viral encephalitis was suspected and the boy was authorized to leave the hospital. He was scheduled to have an MRI six months later.

The boy died the day after he was discharged. An autopsy was requested. External examination of the body showed no injury. There were numerous small, crusted skin lesions on the legs. At autopsy, the organs were congested and there was pulmonary edema with enlargement of multiple lymph nodes. Toxicology tests were negative. Histological analysis revealed pancarditis associated with Aschoff bodies, aseptic mitral valve endocarditis, and myocarditis of the septum. The main neuropathological finding was a sub-acute cerebral infarction of the left centrum semiovale. It was concluded that the cause of death was an acute cardiac arrhythmia secondary to heart failure due to rheumatic heart disease. The boy had suffered undiagnosed rheumatic fever. The brain lesion was attributed to ischemic stroke resulting from an embolism secondary to the heart condition.

Discussion: Rheumatic heart disease is the most serious complication of rheumatic fever, a systemic disease that affects children with a previous Group A beta-hemolytic Streptococcus infection. Around 40% of patients with acute rheumatic fever develop some degree of pancarditis with associated heart failure. Acute rheumatic fever and rheumatic heart disease are thought to be due to an autoimmune response, but the exact pathogenesis remains unclear. The prevalence of rheumatic fever has decreased and is less than 0.05 per 1,000 population in industrialized countries, making it an uncommon cause of sudden death in childhood.

In this case, the issue of medical negligence could be raised, because the boy died the day after he had left the hospital with an inappropriately reassuring diagnosis; however, the presentation was atypical, with prominent neurological signs that were not specific to rheumatic fever and that were subsequently attributed to ischemic stroke. Following hospitalization and investigation, viral encephalitis was suspected which was consistent with the medical history. The diagnosis of rheumatic heart disease was made postmortem on the basis of histology. Although rheumatic fever is infrequent, clinicians should consider this diagnosis when confronted with neurological symptoms in a child with a previous history of fever and rash.

Forensic Pathology, Sudden Death, Rheumatic Heart Disease

H133 Cardiovascular Abnormalities Associated With Sudden Unexpected Death in Epilepsy

Marisa DelMundo-Galicia, MD, County Cook OME, 2121 W Harrison Street, Chicago, IL 60612-3705; and Steven M. White, MD, PhD, County Cook OME, 2121 W Harrison Street, Unit D7, Chicago, IL 60612*

After attending this presentation, attendees will better understand the cardiac abnormalities and other pathologic conditions associated with sudden death in young adults with epilepsy without evidence of a seizure episode at the time of death.

This presentation will impact the forensic science community by providing an overview of cardiovascular abnormalities seen in young adults with seizure disorders who died suddenly, which will be useful in identifying potential causes of death in this population.

Many young adults suffer with seizure disorders, such as epilepsy. While people with seizure disorders can die during a seizure, they also have a higher incidence of sudden death (without evidence of a seizure) when compared with the general population. The reasons for Sudden, Unexpected Death in Epilepsy (SUDEP) remain largely unknown. There is evidence that repeated episodes of hypoxia during seizures may make people more prone to cardiac arrhythmias and even that the medications used to treat the seizures may be arrhythmogenic. The goal of this study is to examine the presence of cardiac abnormalities in SUDEP and describe other pathologic findings associated with SUDEP in young adults.

A search of the Cook County Medical Examiner's Office database from 2011-2013 was performed for people between the ages of 18 and 40 years in which "seizure disorder" or "SUDEP" were listed as either the cause of death or as a contributing factor in death. Autopsy reports were reviewed for evidence of cardiovascular, respiratory, and neuropathological abnormalities. For evidence of structural heart disease, heart weight, chamber dilatation, hypertrophy, or presence of coronary atherosclerosis were evaluated.

Between 2011-2013, there were 775 natural deaths in young adults between the ages of 18 and 40 years. Of these 775 natural deaths, there were 40 (5%) in which "seizure disorder" or "SUDEP" was listed as the cause of death or as a significant contributing condition. Of these 40 cases, 15 (37.5%) were female and 25 (62.5%) were male. Only six (15%) were found to have evidence of seizure activity at the time of death (presence of intramuscular hemorrhage in the tongue) versus 34 (85%) with no evidence of seizure activity. All cases showed evidence of pulmonary edema or congestion and 15% had cerebral edema. With regard to seizure medications, 18 (53%) of the 34 with no evidence of seizure activity and three (50%) of the six decedents who had an evidence of seizure at the time of death were on medication for their seizures. The medication status of the remaining cases at the time of death was unknown. Of the 18 decedents without evidence of a seizure who were on medication, ten had therapeutic levels.

Cardiac abnormalities were present in 62% (21 out of 34) of young adults with no evidence of seizure activity at the time of death. The most common abnormality was cardiomegaly, which was found in 85% of cases (18 out of 21 cases). Each of these had a heart weight greater than 400 grams and there were nine cases with heart weights of greater than 500 grams. In the group of 21 cases with abnormal hearts, 52% displayed left ventricular hypertrophy, 33% had dilated ventricles, and 28.5% had coronary atherosclerosis (no significant occlusions). Histologically, cardiac myocyte hypertrophy and interstitial fibrosis were the most common abnormalities seen. Of the 34 decedents with no evidence of a seizure, 27 (79%) were overweight (BMI >25kg/m²), 16 of which were obese (BMI >30kg/m²). Of the 21 young adults with abnormal hearts, 20 (95%) were overweight (BMI >25kg/m²) and 14 were obese (BMI >30kg/m²).

In this study, it was shown that most young adults diagnosed with seizure disorders have no physical signs of seizure activity at the time of death. Most of these young adults dying suddenly with no evidence of a seizure are overweight or obese and have evidence of cardiovascular disease. The most common cardiac abnormalities identified were cardiomegaly, left ventricular hypertrophy, and chamber dilatation. The results of this study provide insight into potential causes of death in young adults with SUDEP and confirm that clinical surveillance of cardiovascular disease in this population is warranted.

H134 Sudden Deaths in Patients With Cardiac Rhythm Devices Via Medical Examiner Surveillance and Systematic Autopsy

Zian Tseng, MD*, *Electrophysiology & Arrhythmia Service, 400 Parnassus Avenue, Fl B1, Rm 094, San Francisco, CA 94143*; Christopher Mulvanny, BS, *University of California, San Francisco, 400 Parnassus Avenue, San Francisco, CA 94143*; Nina Clark, BS, *University of California, San Francisco, Box 1354, Rm MUE 430, 500 Parnassus Avenue, San Francisco, CA 94143*; Philip Ursell, MD, *Medical Sciences, 513 Parnassus Avenue, Box 0102, Rm 546C, San Francisco, CA 94143*; Jeffrey Olgin, MD, *Moffitt Hospital, 505 Parnassus Avenue, Box 0124, Rm 1182, San Francisco, CA 94143*; Amy P. Hart, MD, *San Francisco OCME, 850 Bryant Street, N Terrace, San Francisco, CA 94103*; Nikolas P. Lemos, PhD, *OCME, Forensic Lab Division, Hall of Justice, N Terrace, 850 Bryant Street, San Francisco, CA 94103*; and Ellen Moffatt, MD*, *City & County of San Francisco, OME, 850 Bryant Street, San Francisco, CA 94103*

After attending this presentation, attendees will understand that cardiac devices such as pacemakers and defibrillators may contain useful information as to the heart rhythm at the time of death, as well as giving important clues as to why the patient died through interrogation of the device and inspection of the programming details and device settings, as well as uncovering possible malfunctions of the device.

This presentation will impact the forensic science community by reminding members of their role in public safety in finding malfunctions and defects in products placed into patients and their duty to help the living by giving feedback to cardiologists who program and implant these devices into patients.

Introduction: Data on device malfunctions are based on the Food and Drug Administration's Manufacturer and User Facility Device Experience (MAUDE) database, participation in which is mandatory for manufacturers but voluntary for healthcare providers; however, because the vast majority of Sudden Cardiac Deaths (SCDs) occur out of hospital, interrogations and autopsies of SCDs with devices are rarely performed; thus, actual rates of device failure that lead to sudden death are unknown. This study was initiated to determine the Causes Of Death (COD) in SCDs with devices in a prospective autopsy study of all incidents of SCDs in San Francisco.

Methods: In the first 30 months of the San Francisco Postmortem Systematic Investigation of SCD (POST SCD) Study (02/1/2011-11/30/2013), autopsies were performed on 468 of 480 (97.5%) of all incident SCDs and demographically matched trauma death cases captured through active surveillance of all deaths reported to the Medical Examiner (ME). Evaluation for all cases included full autopsy, toxicology, histology, and detailed examination of the heart and cranial vault. Device interrogation was performed on all SCDs and selected trauma controls with a device. A multidisciplinary committee reviewed pre-hospital medical records and autopsy results to adjudicate a final COD by consensus.

Results: Twenty-one of 468 (4.5%) incident SCDs and three trauma controls had devices (SCDs: eight Implantable Cardioverter Defibrillators (ICDs), 13 Permanent Pacemakers (PPMs); Trauma: one ICD, two PPM).

Six of eight ICDs showed a terminal rhythm of Ventricular Fibrillation (VF) with undersensing and delayed shock in SCD cases. Acute COD (e.g., pulmonary embolism, lethal toxicology, acute myocardial infarct) was excluded in all six. Three of six ICDs had delay of shock due to Antitachycardia Pacing (ATP) programming in VF zone. Four of 13 PPM showed a terminal rhythm of VF in SCD cases. Three of 13 (23%) PPMs had evidence of malfunction, acute COD was excluded in all three. Two PPM-dependent patients had evidence of acute premortem lead fracture; one PPM-dependent patient had rapid battery depletion the day prior to death. Search of MAUDE showed no prior deaths reported for the two leads.

All three trauma control cases showed no evidence of device malfunction at or around the time of accidental death.

Conclusions: By prospective ME surveillance, arrhythmic sudden death despite ICD was common, often due to undersensing and/or delay of VF therapy. VF was the most common mechanism of death in PPM SCDs, followed by lead fracture. Without systematic interrogation and autopsy, these events would have been missed, thus current calculated rates of malfunctions are likely substantial underestimates.

Sudden Cardiac Death, Pacemaker, Defibrillator

Pathology/Biology Section - 2015

H135 A Case of Maternal and Fetal Death by Spontaneous Rupture of Splenic Artery Aneurysm (SAA) in a Nulliparous Pregnancy at the Third Trimester

Monica Salerno, MD, PhD*, Ospedale Colonnello D'Avanzo, Viale degli Aviatori, 1, Foggia 71100, ITALY; Dania De Carlo, MD, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; Benedetta Di Battista, MD, Viale degli Aviatori, 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; Gabriela Perilli, MD, Viale degli Aviatori 1, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; Stefania C. Bello, MD, Ospedale Colonnello D'Avanzo, viale degli Aviatori, Foggia 71100, ITALY

The goal of this presentation is to examine the clinical and histopathological aspects of a case of SAA in a nulliparous pregnant woman at the third trimester.

This presentation will impact the forensic science community by illustrating the necessity of considering the occurrence of atypical and unrelated symptoms in pregnant women, especially in the third trimester, that could require prompt attention in diagnosing SAA rupture before a catastrophic evolution in hemorrhagic shock, characterized by an increased risk of maternal and fetal death.

SAA is the third most common intra-abdominal aneurysm (after aortic and iliac artery aneurysms), and the most common splanchnic artery aneurysm (60% of all visceral aneurysms). Its incidence is between 0.02% and 10.4% in the general population, with a prominent occurrence in women (4:1 female-to-male ratio), commonly multiparous pregnant women. More than two-thirds of aneurysms of the splenic artery are true aneurysms; infrequently they are pseudoaneurysms. They are usually saccular and occur at a bifurcation in the splenic hilum. The true cause of SAA formation is unclear; however, an increase in splenic blood flow may play a role in the development of SAA in patients with portal hypertension. The increased prevalence in multiparous women may be related to increased splenic blood flow and the effects of estrogen on the elastic tissue of the tunica media. Approximately 80% to 95% of SAAs are asymptomatic until rupture and are incidentally found during evaluation of unrelated symptoms, such as left upper quadrant pain, nausea, and vomiting. The most ominous presentation is hypovolemic shock secondary to aneurysmal rupture; however, the overall risk for rupture is low, about 5%, and it is associated with aneurysm size of at least 2cm, commonly during the last trimester in multiparity pregnancy. Rupture of the SAA is associated with a disproportionately high maternal and fetal mortality rate, 64%-75% and 72.5%-95%, respectively. Fortunately, it is observed to be a rare event. The major contributing factors to mortality are the minimal prodromal symptoms and the misdiagnosis with other common obstetric emergencies, like placental abruption, uterine rupture, or amniotic fluid embolism, as well as pulmonary thromboembolism, cholecystitis, appendicitis, or perforated peptic ulcer disease. In the non-pregnant population, mortality has been reported to be approximately 10%-25%. Fortunately, SAA is more frequently diagnosed today than in the past decades with the advancement and liberal use of imaging modalities.

A 28-year-old nulliparous, 39-week pregnant woman was taken to the emergency room showing 90/60mmHg blood pressure, 58b/min pulse rate, 90% SpO₂, and 15 score Glasgow Coma Scale (GCS). Her past medical history was unremarkable. After 25 minutes, the patient suddenly developed a shock status. She was immediately intubated and, despite the resuscitation efforts and epinephrine, a cardiac arrest occurred and the woman died. The gynecologist decided to deliver the fetus by cesarean section and before incision he described the wall of the uterus as pale but intact. A live fetus was delivered, with zero Apgar Score at birth, and three Apgar Score at five minutes. The exploration of the peritoneal cavity revealed a massive hemoperitoneum and 3,000cc of blood were removed. The prosecutor's officer requested an autopsy to verify if a rescue delay occurred.

The autopsy showed a transverse laparotomy with Pfannenstiel incision. The lesser sac was found to be filled with 30cc of blood and 60 grams of clots; a careful examination showed a 2cm splenic artery saccular aneurysm arising from the distal third of the artery's length, 2cm near the splenic hilum, in which was found a 5mm in length rupture.

The uterus presented a sharp lower uterine segment incision due to transverse cesarean delivery.

A complete histological examination was also performed using Hematoxylin-Eosin (H&E) staining, confirming the typical aspect of a hypovolemic shock, lack of blood in all organs with hypoxic-ischemic changes in particular of cerebellum and heart. The study of placenta after formalin fixation was unremarkable.

In conclusion, the cause of death was attributed to a hypovolemic shock due to the rupture of a splenic artery saccular aneurysm in a 3rd trimester pregnant woman and any responsibility of the rescue team was excluded. The infant died after four months due to hypoxic-ischemic brain injury.

H136 Sudden Death in an 11-Year-Old Child With Epilepsy

Peter T. Lin, MD, 200 First Street, SW, Rochester, MN 55905; and Jadee L. Neff, MD, PhD, Mayo Clinic, 200 First Street, SW, Rochester, MN 55905*

After attending this presentation, attendees will appreciate the potential value of examining the cardiac conduction system in Sudden Unexplained Death in Epilepsy (SUDEP) and will have a better understanding of proposed mechanisms of death in SUDEP.

This presentation will impact the forensic science community by calling attention to a seizure-related death where a cardiac conduction system examination was critical for revealing a pathologic abnormality that explained the likely mechanism of death and by suggesting that routine cardiac conduction system examination may be warranted in unexplained deaths associated with seizures.

SUDEP is the most common cause of death related to epilepsy, yet the precise mechanism of death remains poorly understood. Cardiac arrhythmia induced by seizure, possibly in combination with a genetic predisposition for arrhythmia, is the most commonly proposed mechanism of death in SUDEP. Other proposed mechanisms include asphyxia due to external obstruction of airway and unwitnessed status epilepticus. Notably, each of these mechanisms of death is likely to have minimal abnormal findings at autopsy. As a cause of death, SUDEP essentially remains a diagnosis of exclusion based on a history of epilepsy, findings or witness accounts indicative of a peri-mortem seizure, and lack of another cause of death revealed through complete autopsy, scene investigation, and ancillary studies.

A case of an 11-year-old girl with a history of seizures and attention-deficit-hyperactivity disorder, who first developed seizures approximately 1½ years prior to death is reported. A detailed neurologic evaluation did not reveal the etiology of the seizures, although magnetic resonance imaging of the brain suggested the presence of mesial temporal sclerosis. She was diagnosed with epilepsy and started on levetiracetam, which was effective in controlling her seizures; however, approximately six months later, she suffered a prolonged witnessed seizure followed by cardiac arrest. She was successfully resuscitated without any neurological deficits and was admitted for comprehensive neurologic and cardiology evaluations. No notable abnormalities were found and she was discharged home. Approximately two weeks later, she suffered another witnessed seizure followed again by cardiac arrest. This time resuscitation was not successful and she was pronounced dead.

Postmortem examination, including cardiac conduction system examination, revealed a focal recent, but healing, myocardial infarct of the summit of the ventricular septum abutting the AV bundle. There was granulation tissue reaction within the infarct, compatible with the infarct occurring around the time of the initial cardiac arrest two weeks prior. The remaining histologic sections of the heart were normal. There were no other infarcts of other organs in the body with a similar histologic age. Neuropathologic examination was notable for a remote 0.3cm cerebellar infarct, subpial gliosis consistent with prior seizure activity, and changes consistent with acute hypoxia. Mesial temporal sclerosis was not identified.

The focal myocardial infarct explains the mechanism of the second cardiac arrest as probably a cardiac arrhythmia. The histologic age of the myocardial infarct suggests the infarct occurred around the time of the initial cardiac arrest two weeks prior to death, perhaps due to inadequate circulatory flow and subsequent ischemic injury; however, there were no other organizing infarcts in other regions of the heart or in other organs and the region of the AV node is not known to be particularly prone to ischemic injury; therefore, this explanation is not entirely adequate. Furthermore, the presence of the infarct does not explain the seizures that preceded both episodes of cardiac arrest since witnesses provided compelling testimony that the seizure preceded cardiac arrest rather than vice versa.

A remarkable aspect of this case report is that the only pathologic abnormality in the heart was found in the cardiac conduction system. The cardiac conduction system is not routinely examined at autopsy. Even in cases of otherwise unexplained deaths, medical examiner/coroners will sporadically put through the conduction system for histologic examination as an exercise in completeness with little expectation of finding a significant abnormality; however, this case suggests that routine examination of the cardiac conduction system may be warranted in cases of sudden death associated with seizures.

Myocardial Infarction, Conduction System, SUDEP

H137 Next Generation Sequencing Technology for the Identification of Genetic Markers Associated With Sudden Unexplained Death and Sudden Infant Death Syndrome

*Roger Kahn, PhD**, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; *Nicole Methner*, 2450 Holcombe Boulevard, Ste 7, Houston, TX 77021; *Michael A. Donley, MS*, 1885 Old Spanish Trail, Houston, TX 77054; and *Katherine Welch, MSFS*, Harris County IFS, 1885 Old Spanish Trail, Houston, TX 77054

After attending this presentation, attendees will understand how the use of next generation sequencing technology to identify genetic markers associated with Sudden Unexplained Deaths (SUDs) and Sudden Infant Death Syndrome (SIDS) can provide a lower-cost alternative to traditional genetic testing methods.

This presentation will impact the forensic science community by demonstrating the potential advantages of using next generation sequencing to identify genetic markers associated with SUDs and SIDS and the advantages of this approach over existing methods.

In the United States each year, there are thousands of deaths of young adults and infants for which there is no determinable cause of death at autopsy. After postmortem investigation, these cases are often listed as SUDs or SIDS. It is estimated that up to 30% of SUD and 10% of SIDS cases could be attributed to potentially lethal and heritable mutations in genes associated with cardiac function. Tests are currently available to identify these genetic variants; however, due to the labor-intensive nature of the traditional sequencing methods used, the identification of putative SIDS/SUD mutations can cost \$5,000 or more per case to sequence only 11 of these genes. This type of testing is prohibitively expensive for medical examiner's and coroner's offices. The purpose of this project was to develop and validate a cost-effective molecular autopsy tool to aid in the determination of cause of death for autopsy negative SUD and SIDS cases. In collaboration with the Baylor College of Medicine Human Genome Sequencing Center, the exomic regions of 65 genes implicated in cardiac arrhythmia and/or sudden death were sequenced using next generation sequencing on the Illumina® HiSeq platform. This allowed a sequencing of a much greater number of genes with a ten-fold *decrease* in cost. More than 300 decedent samples from a Harris County Institute of Forensic Sciences SIDS and SUD cohort were sequenced for lethal mutations. Within this cohort, over 1,000 potential pathogenic variants were identified. After a comprehensive biochemical and functional analysis, the cases where pathogenic mutations were identified were further analyzed for confirmation by the Baylor College of Medicine Medical Genetics Laboratory, a Clinical Laboratory Improvement Amendments (CLIA) -accredited laboratory. Approximately 3%-5% of the cohort was identified as having a lethal genetic mutation, which is significantly less than previously reported estimations. Studies in collaboration with Baylor College of Medicine Center for Medical Ethics and Health Policy are ongoing to develop criteria for reporting final results to family. This presentation will summarize the methods and the sequencing results as well as the process for confirming the findings and proposed reporting guidelines.

Next Generation Sequencing, SIDS, SUDS

H138 Sudden Cardiac Death Due to Anabolic Androgenic Steroids (AAS): Autoptic, Histopathological, and Toxicological Findings in Four Cases

Francesco P. Busardo, MD*, via del vespro, 129, Palermo, ITALY; Enrico De Dominicis, MD, Via Montpellier, 1, Rome, ITALY; Francesco Ventura, MD, via de Toni, 12, Genova 16132, ITALY; Simona Napoletano, MD, Viale Regina Elena 336, Rome, ITALY; Simona Zaami, PhD, viale Regina Elena, 336, Rome 00161, ITALY; and Carmela Fiore, MD, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY

The goal of this presentation is to examine the cardiovascular effects of AAS chronic abuse. In all cases of sudden death in apparently healthy bodybuilders, an accurate circumstantial investigation is fundamental in order to confirm the AAS abuse; the autopsy, histological, and toxicological investigation can ascertain the cardiac pathological features correlated to the abuse of this group of substances.

This presentation will impact the forensic science community by providing the pathological relationship between androgenic-anabolic steroid abuse and sudden cardiac death.

Introduction: Bodybuilders use AASs to increase strength, lean body mass, and, in some cases, to improve physical appearance. This class of substances is able to increase the risk of sudden cardiac death. Here four fatal cases are reported.

Case 1: A 32-year-old bodybuilder suddenly lost consciousness and died during a weightlifting workout at the gym. For several months, he had taken testosterone propionate (700mg/week) and nandrolone (200mg/week) parenterally; he had also taken stanozolol (70mg/wk) orally. His medical history was unremarkable.

Case 2: A 29-year-old bodybuilder was found unconscious during the morning lying on the bed in his apartment. Family members and friends reported he had been using anabolic steroids parenterally (250mg/week of nandrolone and 350mg/week of stanozolol) for several months.

Case 3: A 30-year-old competitive bodybuilder, who worked out regularly at the gym, suddenly collapsed at home and died. In an ashtray near the body, a 2ml vial of nandrolone decanoate was found along with a used 2.5ml syringe. All witnesses confirmed that the subject had started using AAS approximately six months before his death.

Case 4: A 28-year-old amateur bodybuilder was found dead by his father lying on the bed in his bedroom. Family members reported that he had a long history of AAS abuse.

For these four cases, a complete postmortem examination as well as histological and toxicological analyses were performed.

Results: *Case 1:* The body was that of a well-built man (height 189cm, weight 90kg) with a prominent muscular build. The 450g heart was normal in shape, with no cavity dilatation. Its dimensions (14x14x4cm) and wall thicknesses all fell within the normal ranges. The coronary arteries were unremarkable. A grayish area in the internal half of the anterior-lateral wall of the left ventricle was found. Histologically, the grayish area corresponded to typical infarct necrosis with a histologic age of approximately 15 days. *Case 2:* The body was of a well-built man (weight 72kg, height 166cm). All organs were normal. In particular, the dimensions of the heart were 11x10x5cm, the weight was 390g. Histology did not reveal any pathological changes, only focal myocardial cells with contraction bands and segmentation of the myocardial cells similar to those seen in case 1, were found. *Case 3:* The body was that of a well-built man (weight 90kg, length 178cm). The autopsy revealed abnormal muscle development, testicular atrophy, and hepatomegaly. The heart weight was 400g. The wall thicknesses were normal. The coronary arteries showed scattered fatty streaks. Histopathological examination of the heart revealed focal myocardial fibrosis. The liver showed cholestasis and vascular gaps compatible with the diagnosis of peliosis hepatis. *Case 4:* The body was that of a well-built man (weight 87kg, length 176cm). The heart had a normal shape and was normal in size (13cmx11.5cmx3.5cm) but weighed 470g. The left and right coronary showed 75%-80% lumen reduction. Histologically, the myocardial samples showed wide fields of myocardial necrosis characterized by hypercontraction of the myocells. In all cases, a complete toxicological analysis confirmed the presence of AAS in the biological specimens, whereas other recreational drugs or ethanol were not detected.

Conclusions: The morphologic findings and the toxicological results are able to explain the deaths of the four bodybuilders, as related to the cardiac effects of AAS abuse. Therefore, the warning against the use of these drugs by athletes is reinforced and heightened surveillance for AAS-related death that may be under-recognized and under-reported in the medical literature is encouraged.

Anabolic Steroids, Sudden Death, Toxicological Findings

H139 The Challenges Faced in Evaluating a Death Related to Left Ventricular Assist Device (LVAD)

Abraham T. Philip, MD*, Regional MEO, 325 Norfolk Street, Newark, NJ 07103; Megan Keane-Tarchichi, MD, PA; and Yvonne Yetman, RN, Regional MEO, 325 Norfolk Street, Newark, NJ 07103

After attending this presentation, coroners and forensic pathologists will understand the appropriate process involved in the evaluation of a decedent with an implanted LVAD and thus avoid some of the pitfalls experienced by others.

This presentation will impact the forensic science community by raising the awareness about an option that has been recently made available for the treatment of Congestive Heart Failure (CHF): the implantable LVAD, of which there are now a variety of devices in developmental stages in clinical trials and in routine use.¹ The limitations of the process involved in the evaluation performed at the Regional Medical Examiner's Office in Newark, NJ, for a decedent with a LVAD are described. The criteria for the use of LVADs, a brief review of the types and functioning of these devices, and their therapeutic complications will also be outlined.

A 57-year-old man was transported from his residence to the nearest health care center after being found unresponsive by his spouse. His downtime was estimated at 20 minutes. His past medical history was significant for end-stage CHF, status post-LVAD implantation, atrial fibrillation, status post-pacemaker implantation, gout, hypothyroidism, and obesity (Body Mass Index (BMI)=30.7kg/m²). He was later transported to the local area major medical center, where his LVAD had been previously implanted. He was diagnosed with anoxic encephalopathy and pronounced dead after failure of resuscitation.

At autopsy, he had a 942 gram heart with concentric biventricular myocardial hypertrophy. Gross examination of the heart revealed prominent subendocardial fibrosis in the left ventricular outflow tract and partial fusion of the aortic valve cusps, a finding that has been reported in the literature.¹ Evaluation of the heart and the device at autopsy revealed no loss of integrity of the anastomosis and no bleeding or evidence of infection. Additional autopsy findings included pleural and peritoneal effusions, passive venous congestion of the liver, and marked pulmonary congestion with numerous heart failure cells. The toxicology screen was negative. Besides the complete autopsy, the LVAD and pacemaker were evaluated by the respective manufacturers.

CHF affects approximately five million patients in the United States and about a half-million new patients are diagnosed with the condition every year. While there are pharmaceutical options for the treatment of CHF, the survival rates and quality of life with these therapies remains suboptimal. An alternative remedy is cardiac transplantation; however, as is well known to the forensic pathology community, the major limitation for this option is the availability of donors for the procedure. The research into the development of an artificial heart was initiated at the National Institute of Health in 1964. In 1994, the Food and Drug Administration approved the use of LVADs, initially as a bridge to transplantation. The device is currently used as a destination device for those too ill for cardiac transplantation.

Immediate complications of LVAD use include postoperative bleeding, with the necessity of massive transfusions with all its associated risks, and infection involving the operative site resulting in sepsis. A slightly more ominous complication is acute gastrointestinal bleeding due to the formation of arteriovenous malformations in the stomach and intestines. Other reported complications include pulmonary insufficiency with right heart failure and transient cerebrovascular ischemic episodes or strokes. The manufacturers are attempting several innovations to reduce these complications.

Several challenges were experienced while evaluating the cause and manner of death in the decedent described above. While there are several articles on the topic of LVAD in the clinical literature, a review of the forensic literature revealed only one article on this topic.¹

LVAD, Congestive Heart Failure, Sudden Death

Pathology/Biology Section - 2015

H140 Cardiovascular Pathology in Cases of Death Following Autonomic Failure

*Enrico A. Riso, MD**, Via Alfredo Catalani 10/26, Genova 16154, ITALY; *Paolo Garofano, MD, PhD*, Accademia Italiana di Scienze Forensi, via Manlio di Veroli, 3, Rome 00199, ITALY; *Dragan Primorac, MD, PhD*, 471 Wolcott Lane, Orange, CT 06477; and *Maurizio Cravello, MD*, via Ronco 8, San Maurizio Canavese 10077, ITALY

After attending this presentation, attendees will be able to identify common, less common, and very rare histopathologic findings of the heart and its conduction system following a sudden death due to a derangement of the autonomic nervous system. Attendees will be taught the appropriate approach for the examination of the heart. Different dissection and sampling techniques, together with different histology, staining procedures, immunohistochemistry, and DNA analyses will also be presented.

This presentation will impact the forensic science community by approaching the concept of “neurocardiology” in a multidisciplinary way. The goal of this study is to provide new tools and guidelines for the medical examiners attending a case in which a failure of the autonomic nervous system is regarded to be the triggering factor in the chain of events leading to death.

Central autonomic failures may result in several cardiovascular complications ranging from reversible Electrocardiogram (EKG) changes to a well-established myocardial infarction. It is well recognized that physical and emotional stress (such as physical pain, anxiety, and anger) may result in sudden death following a major, apparently “inexplicable,” cardiac event. These mechanisms are known to be responsible for more than 300,000 sudden cardiac deaths every year in the United States.

During the presentation, the chain of cellular events resulting either in reversible cell injury or death of the myocytes will be explained briefly. After the explanation of the process involving cardiac physiology and physiopathology, attendees will be shown a series of cases in which the autonomic nervous system was found to be the only trigger factor for the development of a myocardial ischaemia or an infarction. At the time of the autopsy, all of the decedents were found to have patent coronary arteries, no abnormalities to the cardiac conduction system, and negative DNA analyses for the most common channelopathies. Both the macroscopic and the microscopic examination of the organs (with the exception of the heart) were unremarkable. The toxicological analyses were negative and there was no history of previous diseases or alcohol or drug abuse.

The goal of this study is to link the histopathological findings to the concept of neurocardiology. The most common EKG changes (when recorded shortly prior to death) will be shown and compared with the related “neurocardiac lesions” such as myofilament disintegration, coagulation necrosis, colliquative myocytolysis, coagulative myocytolysis (contraction band necrosis) and macroscopically, subendocardial hemorrhages, and/or a well defined myocardial infarction. The attendees will also be taught how to assess the different dating of the above-mentioned injuries using different tools such as the degree of inflammatory response, different histological stains, immunohistochemistry, and DNA analysis. Further “ancillary” analyses, techniques of fixation, and dissection will also be discussed.

After the presentation of several cases, a comprehensive explanation of the biochemical derangements and their underlying intracellular mechanisms, attendees will be able to recognize the different types of “neurogenic heart disease” such as those caused by increased plasma levels of catecholamines, increased or decreased plasma levels of steroids (e.g., fluorocortisol), or a sudden intracellular calcium influx.

Sudden Death, Autonomic Failure, Cardiovascular Pathology

H141 Myocardial Rupture and Cardiopulmonary Resuscitation: Diagnosis and Forensic Issues

*Isabelle Plu, MD, PhD**, Institut Médico-Légal, 2 Place Mazas, Paris 75012, FRANCE; *Jean-Marc Laborie, MD*, Institut Médico-Légal, 2 Place Mazas, Paris 75012, FRANCE; *Thierry Lefrancq, MD*, Le Vauban, BP 549, 16 rue Clerget, Nevers 58009, FRANCE; *Isabelle Sec, MD*, IML de Paris - Place Mazas, Paris 75012, FRANCE; and *Bertrand P. Ludes, MD, PhD*, Institut Médico-Légal, 2 place Mazas, 75012 Paris 75012, FRANCE

After attending this presentation, attendees will better understand traumatic, particularly myocardial, injuries due to Cardiopulmonary Resuscitation (CPR).

This presentation will impact the forensic science community by helping differentiate traumatic myocardial rupture due to CPR from other causes of rupture such as myocardial infarction and by recognizing risk factors of heart injuries due to CPR.

Chest compression is the main component of CPR and provides minimal blood flow despite cardiac arrest. Since the 1960s, skeletal injuries related to chest compression have been described, in particular, sternum and anterior rib fractures. They are frequent (in 25%-30% of patients) but are usually not fatal. To the contrary, visceral injuries such as lung contusions, heart or hepatic hematomas or ruptures, and splenic ruptures due to CPR are uncommon but may lead to the death of the victim.

Heart rupture, which is a particular autopsy finding, raises several questions: (1) is the heart rupture traumatic due to blunt force trauma or non-traumatic due to a pre-existing cardiovascular condition (e.g. cardiac infarction or myocarditis); (2) if the rupture is traumatic, what kind of mechanism may be involved? In cases of chest trauma, are the lesions due to CPR or to the initial injuries; and, (3) is death due to the primary cause of cardiac arrest or due to the CPR-related heart injury? In order to illustrate and delve more deeply into this matter, this study will present five cases of heart ruptures after CPR. The cases that will be presented include three women aged 35, 34, and 48 years old (Cases 2, 3, and 5), and two men aged 29 and 23 years old (Cases 1 and 5). The three women were underweight (Cases 2, 3, and 5); in two cases, the body weight was within normal range. Cases 1 and 4 had unexplained syncope in the presence of witnesses, whereas Case 5 lost consciousness after facial trauma in front of his assailant. In Cases 2 and 3, the women were found hanged by their partners. CPR was undertaken by medical emergency teams and initially by laypersons in Cases 3 and 5.

Autopsies found right atrium rupture in Case 3, right ventricle rupture in Cases 1 and 2, and left ventricle rupture in Cases 4 and 5. These ruptures were associated with hematoma of the left atrium in Cases 2 and 3, with hematomas of the aortic arch in Cases 4 and 5, of the pulmonary hilum in Cases 2, 4, and 5, of left interlobar fissure in Case 5, and of the descending thoracic aorta in Case 4.

Hemopericardium of variable volume from 50-300ml was found in all cases. Hemothorax less than 100ml was found in Cases 4 and 5. There was no case of lacerations of the pericardium. Two cases (2 and 4) had pericardium hematoma. Four cases presented with anterior or anterolateral rib and sternum fractures. A 70% coronary stenosis was found in Case 4, but without thrombosis or myocardial infarction. Facial bruises with nasal fracture were found in Case 5, but there were no brain injuries.

Microscopic analyses (Cases 1, 2, and 5) did not find cardiovascular pre-existing pathology and concluded that lacerations of the right ventricle (Cases 1 and 2) were postmortem. In Cases 1 to 4, cardiac and mediastinal injuries were found to be related to chest compression during CPR. In Case 5, hemorrhagic infiltrates and myocardial fibers in contraction were found microscopically in the samples of the left ventricle. These observations suggested antemortem injuries due to chest compressions on a still-beating heart.

In conclusion, the probability of CPR-related myocardial rupture is high when associated with sternum and/or rib fractures, when chest compression could be only explained by CPR, and when there is no pre-existing cardiovascular disease. Risk factors are low body weight of the victim, CPR initiated by laypersons, and maneuvers of long duration.

Cardiopulmonary Resuscitation, Heart Rupture, Hemopericardium

Pathology/Biology Section - 2015

H142 Genetic Investigation of Sudden Cardiac Death: The State of the Art in Italy

Antonio Oliva, MD, PhD, Largo Francesco Vito 1, Rome, ITALY*

After attending this presentation, attendees will understand of the protocols used in forensic practice (genetics and pathology fields).

This presentation will impact the forensic science community by providing a full panoramic view of the state-of-the-art in the forensic investigation of Sudden Cardiac Death (SCD) in order to reach the best practice when being presented with these cases in routine workflow, especially regarding genetic analysis. This presentation will also impact the forensic science community by defining the key role played by the forensic pathologist, especially regarding the available options (i.e., genetics, proteomics) in the research and diagnostic procedures of sudden death cases

Background: Forensic medicine defines unexplained sudden death as a death with a non-conclusive diagnosis after autopsy. Molecular diagnosis is progressively being incorporated in forensics, mainly due to improvements in genetics. New genetic technologies may help to identify the genetic cause of death, even though the clinical interpretation of genetic data remains the current challenge. The identification of an inheritable defect responsible for arrhythmogenic syndromes could help to adopt preventive measures in family members, many of them asymptomatic but at risk of sudden death. This multidisciplinary translational research requires a specialized team. In this presentation, the state-of-the-art of the forensic approach to sudden death will be addressed. Two families with a recurrence of sudden death events investigated by molecular analysis will be presented to discuss current possibilities and limitations.

Material and Methods: Direct sequencing of the major contributing candidate genes in two families, originally diagnosed with Brugada syndrome after the probands experienced cardiac arrest and clinical and genetic analysis in their members, was performed. Pathogenicity of the variants was analyzed using family segregation, allele frequency from public databases, and conservation analysis. Phenotype-genotype correlations were analyzed statistically. Direct sequencing identified two different mutations in the SCN5A gene respectively designated E1784K — missense mutation causing the substitution of Glu by Lys — and an insertion of nucleotides TG in domain II (TGins851).

Conclusions: These results support the use of genetic testing as part of the diagnosis of SCD syndromes and to help in identifying relatives at risk of SCD; however, the identification of genetic variations in the clinical and forensic investigation of single patients using bioinformatic tools can produce erroneous conclusions regarding pathogenicity. In fact, distinguishing pathogenic mutations from rare variants is of critical importance in the interpretation of genetic testing. Therefore, segregation studies are the key to determining causality. Mutation type, mutation location, and ethnic-specificity should be viewed as variants of uncertain significance and prompt further investigation to clarify the likelihood of disease causation; however, mutations in regions such as the transmembrane, linker, and pore areas may be defined confidently as high-probability disease-causing mutations. These findings may have crucial implications for other genetic disorders involving mutational analysis, especially in postmortem setting.

Sudden Cardiac Death, Autopsy, Genetics

Pathology/Biology Section - 2015

H143 Homicide by Stroke: Cholesterol Embolus Induced During a Struggle

*Ericka A. Becker, BS**, University of Maryland, Baltimore, 22 S Greene Street, Baltimore, MD 21201; *Brandy Shattuck, MD*, 1000 Oakland Drive, Kalamazoo, MI 49008; and *Rudy J. Castellani, MD*, Department of Pathology, 22 S Greene Street, Baltimore, MD 21201

After attending this presentation, attendees will recognize stroke from atheroembolus (cholesterol embolus) as a potential result of blunt trauma during the course of an altercation, as well as the spectrum of natural disease processes that may be precipitated in a homicidal manner.

This presentation will impact the forensic science community by raising awareness of the possibility of stroke by atheroembolus resulting from blunt trauma received during the course of a homicide. As this is the first such report of homicide by stroke due to atheroembolus, it is most likely an under-recognized entity.

Death from natural diseases precipitated by homicidal acts is uncommon, but well documented in the forensic literature. "Homicide by heart attack" was reviewed in recent years by Turner et al.¹ The situation is made difficult by circumstances in which no physical contact occurs between perpetrator and victim but nevertheless involve fatal arrhythmia induced by emotional or physical stressors. Criteria are available for such circumstances. Similar situations may involve physical contact that by itself is non-lethal but still results in sudden cardiac death. Revised criteria are available for these situations as well. In each case, severe underlying heart disease is present in addition to sublethal injuries. This is the first case of homicide by atheroembolus reported in the literature. The decedent was a 62-year-old Caucasian woman who was found incoherent at home. She was transported to the hospital and expired shortly thereafter. The investigation revealed that an altercation took place between the decedent and a man, possibly involving a head-lock maneuver. The autopsy revealed an obese woman with moderate calcific atherosclerosis involving the coronary arteries, aorta, and major branches. Brain examination revealed calcific atherosclerosis involving the Circle of Willis with a clot in the right middle cerebral artery, and an acute ischemic infarct involving all of the right middle cerebral artery territory, with transtentorial herniation and secondary brainstem (Duret) hemorrhages. Sections of the right middle cerebral artery revealed a large cholesterol embolus.

In conclusion, this is the first case report of a cholesterol embolus becoming dislodged during the course of an altercation, which resulted in a large right hemispheric stroke with mass effect and death. Extrapolating from criteria associated with sudden cardiac death and non-lethal injuries, the manner of death in this case is compatible with homicide. Given the frequency of atherosclerosis and the possibility of cholesterol emboli with trauma, careful examination of the Circle of Willis should be performed, especially in cases in which the victim suffers acute neurologic decompensation following an altercation.

Pathology/Biology Section - 2015

H144 An Uncommon Cause of Pulmonary Embolism

*Adrienne Segovia, MD**, Cook County Medical Examiner's Office, 2121 W Harrison Street, Chicago, IL 60612; *Tasha Z. Greenberg, MD*, Tarrant County MEO, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919; and *Kimberly Golden, MD*, 345 E Ohio Street, Apt 4606, Chicago, IL 60611

The goal of this presentation is to increase awareness of uncommon sources/locations of thromboemboli in patients with autosomal dominant polycystic kidney disease.

This presentation will impact the forensic science community by highlighting the importance of examining the inferior vena cava and pelvic vessels in patients with polycystic kidney disease.

Case: A 20-year-old African American female was found unconscious and pulseless in her bedroom. She was last known alive ½ hour prior to discovery. When an ambulance arrived, paramedics intubated her without difficulty and initiated advanced cardiac life support. On arrival at the emergency department, an intraosseous line was placed and the correct position of the endotracheal tube verified. Despite these efforts she remained pulseless, without respirations and blood pressure, and was pronounced dead after 15 minutes.

Prior to the autopsy, the only available medical history indicated that three days before her death she complained of cold-like symptoms and began taking an antibiotic.

The external examination revealed an African American female measuring 5 feet 3 inches in height and weighing 233 pounds. The lower extremities were symmetrical and did not have edema.

The internal examination found large polycystic kidneys occupying the abdominal cavity and extending into the pelvis. The right kidney weighed 1,421 grams and measured 22cm in length and 12cm in width. The left kidney weighed 1,456 grams and measured 19cm in length and 13cm in width (normal range for women — weight: 115-155 grams, length: 11-12cm, width: 5-7cm). The right lung weighed 313 grams and the left lung weighed 299 grams. The pleural surface of the left upper and lower lobes revealed darker red/tan areas respectively measuring 3cm and 3.5cm. The cut surfaces through these areas were consistent with the appearance of pulmonary infarcts.

Opening the pulmonary trunk and the right and left pulmonary arteries revealed thromboemboli which ranged from 1cm to 6cm in length and up to 1cm in width. The proximal right and left pulmonary arteries had adherent thromboemboli. The right and left iliac veins and the inferior vena cava had adherent thrombi. Examination of the veins of the lower extremities was negative for thrombi.

There was mild cardiomegaly (heart weight: 396 grams; LV: 1.6cm) with normal valves and bilateral polycystic ovaries. There were no cysts involving the liver, pancreas, or spleen. There were no aneurysms of the aorta or Circle of Willis. Toxicology was negative for ethanol, cocaine, and heroin. Vitreous electrolytes had a normal postmortem pattern. A nasopharyngeal viral culture was negative.

The patient's mother confirmed that her daughter had polycystic kidney disease and was followed by a physician for her disease but had been putting off going to see her doctor for over a year because she had no complaints, such as fullness in her abdomen, leg pain, and/or swelling.

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is one of the most common inherited disorders and is the most frequent genetic mutation leading to renal failure in adults, accounting for % to 8% of patients on dialysis in the United States. The disease is progressive, can affect multiple organs systems, and is characterized by the formation and enlargement of cysts in the kidneys. Extra-renal cysts are most commonly found in the liver. The clinical features usually begin in the third to fourth decade of life, although cysts can be detected in childhood and *in utero*. Although the presentation of the disease is highly variable, the most common initial complaint is pain and/or discomfort in the abdomen, flank, or back, typically as the result of liver and kidney cysts exerting pressure in these areas.

ADPKD is caused by mutations in one of two genes — PKD1 which codes for polycystin 1 and PKD2 which codes for polycystin 2. Approximately 85%-90% of patients with ADPKD have the PKD1 mutation (ADPKD 1) located on the short arm of chromosome 16 (16p13.3). ADPKD 2 accounts for 10%-15% of cases. The mutation is found on the long arm of chromosome 4 (4q21-22). Individuals with ADPKD 1 have an earlier mean age of onset of end-stage renal disease (53 years), compared to those with ADPKD 2 (74 years).

Pathology/Biology Section - 2015

Two studies have described the causes of death in 217 patients with ADPKD. Prior to 1975 and the use of renal replacement therapy, the average age of death was 51 years, increasing to 59 years by 1995 and 60.5 years by 2009. Cardiac disease is responsible for most deaths, followed by infection and central nervous system causes. A total of eight individuals died as the result of pulmonary embolism. Although detailed information was not available for these patients, there was no thrombosis of the vena cava or renal vein noted in seven of the eight patients.

Only a handful of cases of pulmonary embolism due to thrombosis of the inferior vena cava and/or ileofemoral vessels caused by compression of the infra-hepatic inferior vena cava by renal cysts have been reported. None of these were fatal and the development of thrombosis of the inferior vena cava was independent of renal function.

The risk factors for the development of a pulmonary embolism are well known. There was no history of coagulation abnormalities, immobility, or cancer in this patient. Although this patient had a BMI of 41.3, placing her in the obese category, it is proposed that thrombosis of the inferior vena cava and iliac veins was a result of extrinsic compression by the kidneys and death was due to pulmonary embolism caused by compression of the inferior vena cava and pelvic vessels due to polycystic kidney disease.

Polycystic Kidney Disease, Pulmonary Embolism, Inferior Vena Cava

Pathology/Biology Section - 2015

H145 A Novel Approach to a Quality Program in a Medical Examiner's Office

*Sam W. Andrews, MD**, Office of Medical Investigator, 1101 Camino de Salud, NE, Albuquerque, NM 87102; and *J. Keith Pinckard, MD, PhD*, Office of the Medical Investigator, MSC07 4040, 1 University of New Mexico, Albuquerque, NM 87131-0001

After attending this presentation, attendees will understand a robust quality program implemented in a statewide medical examiner's office.

This presentation will impact the forensic science community by setting a high standard of quality in a medical examiner's office using concepts of reasonableness that are independently reviewable.

Forensic pathology is a sub-specialty of pathology responsible for the determination of cause of death in individuals dying suddenly, unexpectedly, or violently. Just like other branches of pathology and laboratory medicine, a robust quality control and quality assurance program is essential to ensure the product generated is of the highest quality to best serve the families of the deceased and the medicolegal communities. Although there are no minimum standards to which medical examiner/coroner offices must adhere, the National Association of Medical Examiners (NAME) offers a voluntary accreditation that attempts to ensure that offices meet a minimum set of criteria for death investigation. Having a functional quality assurance program is a component of this accreditation; however, NAME only dictates that a quality program is in place and documented; it neither specifies how the program should be structured nor does it specify any details such as a percentage of cases to be reviewed or whether reviews are to be prospective or retrospective. The New Mexico Office of the Medical Investigator have developed one of the most comprehensive and robust Quality Programs (QP) in the field of forensic pathology.

The QP has two arms: a Quality Assurance (QA) arm and a Quality Control (QC) arm. QA is defined as a prospective activity to ensure that the death investigation report is of the highest quality with reasonable conclusions as to the cause and manner of death. This program defines QC as a retrospective activity to ensure completed death investigation reports have met a high standard of quality with reasonable conclusions as to the cause and manner of death.

Reviews focus on the concept of what is "reasonable" because it is recognized that forensic pathologists can have a legitimate difference of opinion regarding cause and manner of death and it is also possible that both opinions are reasonable. Even though a peer reviewer may disagree with the opinions of the original pathologist, the conclusions are deemed reasonable if the reviewer can follow the logic used and understand how decisions and diagnoses were made. Another key component of the program is to ensure that all reports are "independently reviewable," which means that another forensic pathologist would have a sufficiently objective dataset (e.g., photographs, microscopic slides) to come to his/her own conclusions about the case and be able to agree or disagree with the conclusions reached by the autopsy pathologist. This is absolutely necessary to enable a quality review and also ensures that the report would be able to be reviewed by an external reviewer or another expert witness in the future.

The QA component reviews all homicides, all cases with an undetermined manner of death, and all deaths of children younger than five years (60 months) of age. This review is performed prior to completion of the case. The QA review of the pediatric cohort is slightly different: a committee chaired by the Director of Pediatric Forensic Pathology and consisting of the QP pathologist for the month and the forensic pathology fellows reviews the cases and forms a consensus opinion.

The QC arm is an administration-directed retrospective review of completed death investigations including Office of Medical Investigator (OMI) jurisdictional and consultation autopsies, pathologist external examinations, and investigator external examinations in cases with natural, accidental, and suicidal manners of death. In practice, with seven full-time forensic pathologists at the OMI, the QC arm will review 252 cases in this cohort annually.

The QP has not yet been implemented for a full year, but in 2012 (the most recent year with available data), there were 160 homicides, 1,578 natural deaths, 419 suicidal deaths, 1,458 accidental deaths, and 98 deaths of undetermined manner certified by forensic pathologists at the OMI. Included in these cases were 181 deaths of children under five years of age regardless of manner of death. In 2012, therefore, the two arms of the QP collectively would have reviewed 658 death investigations, or approximately 17% of the death investigations performed by the OMI.

A robust QP that demonstrates and ensures a commitment to producing quality death certifications and death investigation reports has been implemented at the OMI.

H146 **Worked to Death: A Detailed Discussion of At-Work Deaths in Harris County, Texas**

Kathryn H. Haden-Pinneri, MD, Harris Co Inst Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand the importance of investigations of deaths at work and the proper procedures for this type of investigation.

This presentation will impact the forensic science community by providing instruction on the proper steps to take in the investigation of at-work deaths and by increasing awareness of the importance of a thorough investigation, including collaboration with regulatory agencies, such as local Occupational Safety and Health Administration (OSHA) representatives.

Deaths occurring at work are very disconcerting for all parties involved. Finding a co-worker dead or witnessing an accident or event that results in death can be emotionally traumatic. The employer is responsible for maintaining the safety of their employees, so when a fatal accident occurs, they are potentially liable for the death. Regulatory agencies are charged with monitoring and enforcing safety and health regulations in the workplace and the type of workplace determines which agency will be involved. A multi-agency death investigation has many challenges, including proper communication and information sharing. Lack of either may result in further harm to other employees of the business or harm to those doing the investigation and subsequent autopsy.

Harris County, TX, which includes the city of Houston, has 31 different law enforcement agencies and a population of almost 4.1 million people (as of the 2010 United States census). The Harris County Institute of Forensic Sciences (HCIFS) investigates approximately 4,000 deaths each year, of which approximately 3.5% are considered to be deaths at work. Of the at-work deaths, approximately half are due to accidental injury and the other half due to underlying natural disease processes. Accidental injuries can include falls from heights, malfunctioning or improperly utilized machinery, electrocutions, motor vehicle accidents while driving, or exposure to toxic chemicals. Many of these incidents result in the individual being transported to the hospital; therefore, it is critical to have someone respond to the scene of the incident for proper investigation and documentation. Determining the level of training/experience the worker has with the particular equipment being utilized is important and could reveal improper techniques being utilized or uncover the need for better training in order to prevent further injuries. This presentation will review some typical as well as some atypical at-work deaths that were investigated at the HCIFS. Injuries documented during the autopsy should be compared with scene photographs and investigative statements to ensure correct interpretation of the trauma.

Toxicology testing is performed on all at-work deaths reported to the HCIFS. This testing includes, but is not limited to, an alcohol screen and full Enzyme-Linked Immuno-Sorbent Assay (ELISA) screen (cocaine metabolite, amphetamines, Phencyclidine (PCP), opiates, benzodiazepines, methadone, and barbiturates). Due to the prevalence in this region, screening is also performed for carisoprodol/meprobamate and marijuana metabolites. Other substances are tested for as indicated by the scene investigation. Harris County is home to many chemical manufacturing plants; therefore, specific chemical analyses are performed to identify potential exposures. The HCIFS has a collaborative working agreement with local emergency responders to ensure the safety of their employees when responding to scenes involving potentially hazardous materials.

Proper handling of at-work deaths is critical for many reasons, not the least of which is monetary. The potential financial concerns of the employer, the employer's insurance carrier, the family, and the possibility of workman's compensation reimbursement may affect the ability to conduct the investigation. It is important to maintain a fact-based presence with all parties involved in order to obtain the necessary information. Inappropriately maintained equipment found to be implicated in the death of an individual may result in significant fines and reprimands for the employer. On the other hand, the family of an individual who has an accident while impaired by drugs or alcohol may not be entitled to any financial reimbursement. Litigation in these instances can be costly, time consuming, and may hinge on details or information that may not initially seem important. Good communication with all parties involved in a timely fashion could help prevent additional accidents and injuries as well as potentially reducing the number of unnecessary lawsuits.

At-Work Deaths, Accidental Injuries, Scene Investigation

Pathology/Biology Section - 2015

H147 Quality Assurance Projects at the Los Angeles Medical Examiner/Coroner's Office

*Lakshmanan Sathyavagiswaran, MD**, 713 Duarte Road, #G549, Arcadia, CA 91007; and *Christopher B. Rogers, MD*, Los Angeles County MEO, 1104 N Mission Road, Los Angeles, CA 90033

After attending this presentation, attendees will understand the importance of having a Quality Assurance (QA) process in place so the office can: (1) provide a complete, accurate, timely, usable medicolegal death investigation and report to the citizens; and, (2) ensure all reportable contagious diseases are reported to public health agencies and the needs of the public are met, preserving the confidentiality of results as required by law.

This presentation will impact the forensic science community by helping Medical Examiner/Coroner (ME/C) offices provide quality autopsy reports to the public and improve communication between ME/Cs and public health officials, which will be valuable in the response to a potential bioterrorism event.

The CME-Coroner (CME-C) (1992-2013) coordinated the then Department of Coroner (DOC) staff to obtain accreditations from the National Association of Medical Examiners, American Society of Crime Laboratory Directors-Laboratory Accreditation Board-ISO, Accreditation Council for Graduate Medical Education, and the California Medical Association-Institute for Medical Quality and Peace Officer Standards and Training certification.

A standard operating procedure for quality assurance was developed as the goal was to provide a complete, accurate, timely, usable death investigation report to the citizens served. Through DOC/Medical Division QA committees, reporting and investigation mechanisms for sentinel events and procedures to ensure that all department work products meet minimum specifications was established. When a significant quality problem was identified, measurable corrective action was taken and identified errors were brought to the attention of the persons responsible.

As required by county ordinance, all physicians will receive Performance Evaluations (PE) annually. PEs are prepared by CME-C and physician managers. In order to make the physician PE's less subjective and more objective, raters were directed by the CME-C to use the "QA Case Review" forms as a minimum objective guideline when evaluating cases. These forms assure a basic uniform quality in the autopsy reports (i.e., presence or absence of needle track scars in drug overdose cases, bullet trajectory, skull beveling in deaths from firearms, as well as origin of coronary arteries, etc.). The QA forms were developed with templates from the ME offices in Chicago and San Diego. The draft templates with additional quality indicators were discussed at the Medical QA and in the Physician Business meetings and were approved. The forms were placed in the shared drive for use by physicians on a daily basis during the conduction of autopsies for reference to ensure all minimum quality indicators are addressed. Also the Deputy Medical Examiner (DME) manual was revised to provide guidelines on what needs to be done for a specific type of case.

The measures to be discussed in this presentation include assurance of a basic uniform quality in evaluating cardiovascular status in natural deaths, gunshot wound-related deaths, and drugs of abuse-intoxication/overdose-related deaths. The other measure will outline details on how the ME-C carried out a quality assurance project to improve reporting of contagious diseases to public health agencies. The data before and after intervention (process used) and project completion and outcome will be discussed.

Quality, Autopsy, Communication

Pathology/Biology Section - 2015

H148 Forensic Pathologist Concurrence in the Interpretation of Images of Patterned Injuries

Xianming Fang, PhD, East Carolina University, Dept of Biostatistics, 2435F Health Sciences, Greenville, NC 27834; William R. Oliver, MD, East Carolina University, Brody School of Medicine, Brody Medical Sciences Bldg, Greenville, NC 27834; Karen L. Kelly, MD, Brody School of Med at ECU, Forensic Pathology Division, Dept of Lab Med/Pathology, Greenville, NC 27834; and Colleen Tetterton, Division of Forensic Pathology, Dept of Pathology & Laboratory Medicine, 7S-10 Brody Medical Sciences Bldg, Greenville, NC 27858*

After attending this presentation, attendees will have a better, and quantitative, idea of the degree in which forensic pathologists agree on the interpretation of images of patterned injuries of the skin.

This presentation will impact the forensic science community by providing an estimate of precision and verification of forensic pathology diagnoses from images.

A common problem in forensic pathology practice is the evaluation of patterned injuries of the skin. These injuries can provide important information about the nature of an object that was used to inflict trauma on a victim. In some cases, such as gunshot wounds, there is a rich literature on the proper characterization of the injuries and the inferences that can be made; however, in most cases, the interpretation of these patterns is primarily a matter of personal experience and training.

Traditionally, the ability of a forensic pathologist to interpret patterned injury of the skin has been relatively unquestioned at trial; however, over the past few years, there has been an increasing emphasis on more stringent application of *Daubert* criteria. This presentation represents the results of the first of a series of studies to address the basic issue of the ability of pathologists to interpret patterned injuries. This is a preliminary study in which participants were asked to identify “classic” injury patterns. Images were selected from known cases and teaching sets and were vetted by an expert panel. Since the provenance of each image was not investigated independently, this should be considered a verification study rather than a validation study.

A survey was constructed using 68 “classic” patterned injuries. The participants were presented with the images and asked for a diagnosis. The questions were asked in three tiers, with the first question asking for a diagnosis of the general class of injury (sharp versus blunt versus thermal, etc.), the second asking for a class diagnosis within the general class (e.g., laceration versus abrasion versus contusion for blunt trauma), and the third asking for a specific diagnosis (e.g., hammer blow versus baton mark versus tire mark, etc.). In addition, each participant was asked to rate his or her level of certainty.

Participants were recruited through the National Association of Medical Examiners. Emails were sent to all members of the organization. Approximately one-third of those emailed started the survey (363 people) and 210 people completed the entire survey.

This survey was constructed as a starting point for cases in which there would be a uniformly high consensus. Following surveys were expected to present modified images to see how that affected the degree of agreement; however, there was a surprising lack of uniformity of consensus, ranging from 100% as a high to 27% as a low. In addition, for at least one question, the most common tier 3 answer was that the respondent did not know what object caused the injury, but could match it to an exemplar.

A number of statistically significant findings are noted in the preliminary statistical evaluation. For example, physicians, those who had anatomic pathology training, those who performed autopsies as their primary work product (as opposed to administration, investigation, etc.), and board-certified forensic pathologists were more likely to choose consensus answers. When comparing the percent of consensus answers with mean confidence level for each question, there was a high correlation (r between 0.8 and 0.9) for each tier. There was a moderate correlation between providing a consensus answer and confidence at the individual respondent level.

The degree of consensus was significantly higher for tier 1 (most general) than tiers 2 or 3; however, there was a higher level of consensus for tier 3 “most specific” than for tier 3 “class within a particular injury type.” Comments by participants suggest that a possible reason for the higher consensus at the more specific diagnosis was due to the presence of multiple injuries. For instance, in one case, the same blunt object caused both lacerations and abrasions. The tier 2 question asked what injury was more prominent; about half noted lacerations and half noted abrasions, resulting in a low level of consensus. In contrast, the consensus on the specific object was high.

This research was supported by a grant from the National Institute of Justice.

H149 Gone and Forgotten: A Medical Examiner's Nightmare

Mark M. LeVaughn, MD*, OCME, 1700 Woodrow Wilson Avenue, Jackson, MS 39216; Amber M. Plemons, BS, Mississippi State University, 206 Cobb Institute of Archaeology, Mississippi State, MS 39762; and Nicholas P. Herrmann, PhD, Mississippi State University, Cobb Inst Archaeology, Box AR, Dept of Anthro & Mid East Cultures, Mississippi State, MS 39762

After attending this presentation, attendees will better understand the importance of integrating forensic anthropology into a state medical examiner's office. The focus of this presentation will be on the vast progress made with the accumulation of unmanaged skeletal remains at the Mississippi State Medical Examiner's office due to collaboration with the Mississippi State University's Department of Anthropology and Middle Eastern Cultures (AMEC).

This presentation will impact the forensic science community by influencing protocol for skeletal remains in state medical examiners' offices so individuals do not remain unidentified and unanalyzed for numerous years.

In 2010, the state of Mississippi abandoned its policy of nearly 30 years of contract medical examiner services, consisting primarily of non-board certified pathologists and minimal anthropological consultation. Human remains were recovered by coroners and law enforcement agencies with limited to no training. There was no consistent relationship established with a forensic anthropology program, resulting in an accumulation of unidentified and unmanaged skeletal remains.

Many of the remains had limited to no documentation, were lost or never returned by the private consultant, and lacked chain of custody and documentation of follow-up communication between the attending pathologist and the anthropologist to establish a cause and manner of death. In 2011, Mississippi established a State Medical Examiner's office consisting of five board-certified forensic pathologists performing approximately 1,400 autopsies per year. A relationship was established with AMEC to provide professional consultation and a graduate anthropology internship within the State Medical Examiner's Office.

The primary goals of the internship were to address 28 skeletal cases that had accumulated at the Mississippi State Medical Examiner's office, obtain data for the Forensic Osteology (FOROST) trauma metabase, update entries in National Missing and Unidentified Persons System (NamUs), and assist with autopsy examinations. After the initial inventory, the lack of documentation was clear and investigative agencies were contacted to obtain available case histories. Within two months, all remains were inventoried, examined, photographed, and radiographically imaged when necessary. Eight skeletal cases have been identified and released or will be held at the medical examiner's office until directed otherwise, two autopsy reports were generated with cause and manner of death, three cases were entered and one was closed in NamUs, two cases were sent for DNA analysis, and six cases have been documented for entry into FOROST. Additionally, a partially mummified individual, recovered in 2002, was processed for analysis. Examples of these cases, displaying the importance of protocol and anthropological assistance when dealing with human skeletal remains in a medical examiner's office, will be presented.

The Mississippi State Medical Examiner's office seeks to obtain funding for a State Forensic Anthropologist within the State Medical Examiner's office, maintain the Forensic Anthropology internship program, develop a human remains recovery team, train coroners and law enforcement agencies for field recovery, and establish standards within the state to properly search, document, and recover human remains. In conclusion, it is necessary for a medical examiner's office to establish and maintain a structured relationship with a reliable and experienced forensic anthropology program.

Medical Examiner, Skeletal Remains, Anthropological Consultation

Pathology/Biology Section - 2015

H150 Quality Assurance of Autopsy Cultures

*Christopher B. Rogers, MD**, Los Angeles County MEO, 1104 N Mission Road, Los Angeles, CA 90033; and *Nicole Ellis, DO*, Orange County Coroner, 1071 W Santa Ana Boulevard, Santa Ana, CA 92703

After attending this presentation, attendees will be able to implement a quality-assurance system for autopsy culture results and list factors that influence interpretability of cultures.

This presentation will impact the forensic science community by providing information on a quality-assurance program for microbiology specimens taken at autopsy.

Results of bacterial cultures from autopsies are frequently difficult to interpret because of polymicrobial contamination. The forensic literature emphasizes the importance of proper collection technique, as well as interpreting culture results in the clinical context of the case. The most productive areas for culture are blood, lung, and cerebrospinal fluid.

Cultures from autopsies at the Los Angeles County Coroner's Office were retrospectively reviewed for a five-month period to look for factors that are associated with polymicrobial culture results. During the study period, there were 65 bacterial cultures from 47 cases. Fifteen pathologists obtained cultures, with a range of 1-12 cultures per doctor.

The bodies were refrigerated after arriving at the coroner's office, but the time before refrigeration and the time between death and autopsy varied. The preferred technique for obtaining cultures was to heat a scalpel blade and apply it to the surface to be cultured in order to sterilize it. For cultures of skin lesions, the area was sterilized by swabbing with isopropyl alcohol. Blood cultures were taken from the inferior vena cava and other cultures were taken from areas suspicious for infectious lesions. Cultures were taken using either swabs put into transport media or by using a sterile needle and syringe to inoculate blood culture bottles. Cultures were transported within a few hours to a microbiology laboratory.

Highly specific cultures, including cultures for enteric pathogens, acid-fast bacilli, fungi, and results obtained by molecular probes were excluded because of insufficient numbers of specimens and the rarity of false positive results. Also excluded from the study were organisms that are usually contaminants, including coagulase-negative Staphylococci, Diphtheroids, *Streptococcus viridans*, and *Enterococcus*. Cultures were considered interpretable if they either showed no growth or showed a single pathogenic organism.

The most important factor in predicting whether a culture result would be interpretable was the pathologist taking the culture. Results sorted by pathologist showed a range from 0/8 to 8/8 interpretable cultures. The most common postmortem cultures were of blood (6/8 interpretable), bronchus or lung (11/25 interpretable), and meninges or brain (5/7 interpretable). Conditions that were most associated with interpretable cultures included intravenous drug use (5/6 interpretable), meningitis (3/3 interpretable), and abscess (3/5 interpretable). The data did not show an effect of time between death and autopsy, perhaps because of the small number of cases.

The conclusion is that careful culture technique is very important in obtaining interpretable results. Highly selective culture media or molecular probes are helpful in avoiding confusing culture results.

H151 A Comparison of Deaths From Diabetic and Alcoholic Ketoacidosis

Anita Lal, MD*, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Jacqueline L. Parai, MD, Ottawa Hospital, Division of Anatomical Pathology, 501 Smyth Road, Box 117, 4th Fl, Ottawa, ON K1H 8L6, CANADA; and Chris Milroy, MD, LLB, Ottawa Hospital, 501 Smyth Road, Box 117, 4th Fl CCW, Ottawa, ON K1H 8L6, CANADA

After attending this presentation, attendees will understand the patterns of death associated with diabetic and alcoholic ketoacidosis.

This presentation will impact the forensic science community by increasing the understanding of the similarities and differences between deaths due to diabetic and alcoholic ketoacidosis.

Ketoacidosis is an important cause of death encountered at autopsy. Ketoacidosis is most commonly recognized in diabetes mellitus, that is, Diabetic Ketoacidosis (DKA), which is a medical emergency. It may also be seen as a consequence of alcoholism — Alcoholic Ketoacidosis (AKA). Other causes of ketoacidosis include starvation and certain diets. The diagnosis of ketoacidosis is made at autopsy by the presence of ketone bodies (acetone, b-hydroxybutyrate, and acetoacetate). Diabetes mellitus can be identified by history, pathological features (diabetic nephropathy), and by measurement of vitreous glucose or hemoglobin A1C. Alcoholism is typically diagnosed by history and scene findings, which can be supplemented with pathological findings.

This study analyses a series of 151 deaths where ketoacidosis was given as the cause of death in a period from November 2009 to January 2014 in Toronto and Ottawa, Canada. There were a total of 9,332 autopsies, so ketoacidosis represented 1.6% of all deaths. Of these 151 deaths, 82 were reported as deaths due to DKA (0.9% of all deaths), 48 due to AKA (0.5% of all deaths), and 21 as ketoacidosis not otherwise defined or were both diabetics and alcoholics.

Of the 130 DKA and AKA deaths, four DKA deaths and nine AKA deaths were excluded because of insufficient data for analysis or because the principal cause of death was not DKA or AKA, but ketoacidosis was a contributing cause.

Of the 117 deaths, 71 were male and 46 female. The age range was 19-79 years with a mean age of 50.6 years and a median age of 51 years. In relation to the time of year, the deaths were recorded in three-month blocks: March-May=18.8%, June-August=23.9%, September-November=22.2%, and December-February=35%.

The Body Mass Index (BMI) was analyzed with a range of 11.3-52, mean 22.7, and median 21.2.

The main ketone body measured throughout the period of the study was blood acetone. The range varied from not detected to 138mg/100mL with a mean concentration of 28.04mg/100mL and a median of 22mg/100mL.

Of the 78 DKA deaths, 51 were male, 27 female. In 20 deaths, there was no prior history of diabetes mellitus (25.6%). Of the 39 AKA deaths, 20 were male, 19 were female. Comparing DKA and AKA and analyzing the data statistically using the Two-Sample T-Test, the mean age of DKA victims was 49 years, AKA 53.7 years ($p=0.04$), mean BMI in DKA victims was 23.0 and in AKA 22.2 ($p=0.55$). With respect to acetone concentrations, the mean concentration in DKA victims was 33.3mg/100mL and in AKA victims 17.8mg/100mL ($p=0.001$).

In conclusion, DKA is the most common cause of ketoacidosis at autopsy, representing nearly 1% of all deaths and was twice as common as AKA. In 25% of deaths from DKA, there was no prior history of diabetes mellitus. Deaths associated with ketoacidosis were most common between December and February. Victims of DKA and AKA had similar BMIs of 23.0 and 22.2. Mean acetone levels were significantly different between the two groups, being 33.3mg/100mL in DKA and 17.8mg/100mL in AKA victims.

Diabetic, Alcoholic, Ketoacidosis

H152 The Speckled Polarized Lung: Microcrystalline Cellulose Pulmonary Granulomatosis as a Complication of Intravenous Drug Abuse

Wendi G. O'Connor, MD*, University of Florida, Dept of Pathology, PO Box 100275, Gainesville, FL 32610; Yanfei Huang, MD, PHD, University of Florida, Dept of Pathology, PO Box 100275, Gainesville, FL 32610; William F. Hamilton, MD, District ME, 606 SW Third Avenue, Gainesville, FL 32601; and Martha J. Burt, MD, University of Florida, Dept of Pathology, PO Box 100275, Gainesville, FL 32610

The goal of this presentation is to examine the histopathologic findings of microcrystalline cellulose pulmonary granulomatosis from intravenous drug abuse.

This presentation will impact the forensic science community by discussing the case of a lung transplant patient with histopathologic findings of intravenous drug abuse. This case also emphasizes the necessity of suspecting intravenous drug abuse in patients without a reported history in the setting of lung transplantation. Additionally, the pulmonary complications and histopathologic findings of intravenous drug abuse in the setting of lung transplantation will be discussed.

The medical complications of drug abuse are diverse, involving almost any organ and varies with the type of substance and route of administration. Pulmonary foreign body granulomatosis is caused by intravenous injection of pulverized pharmaceutical tablets or more uncommonly by nasal inhalation of drugs. Oral medications commonly contain insoluble binding filler agents that may include microcrystalline cellulose, talc (magnesium silicate), or potato or corn starch. Respiratory complications may involve lung parenchyma, upper airways, pleural space, and pulmonary vasculature.

This study presents a case of a 42-year-old female with a history of chronic obstructive lung disease status post-single lung transplant. Post-operative complications were related to anastomosis, granulation tissue, and narrowing of the right bronchus intermedius requiring frequent dilatation. She was admitted for worsening dyspnea on exertion six months following transplantation. Her hospitalization was complicated by appendicitis, Cytomegalovirus (CMV) viremia, and *Klebsiella* bacteremia. Additionally, she experienced symptoms of non-specific chest pain and tightness. An echocardiogram showed normal Left Ventricular Ejection Fraction (LVEF) with no wall motion abnormalities. Chest radiographs demonstrated non-specific changes. The decedent fell in her room striking her head and was found pulseless. Despite extensive cardiopulmonary resuscitation, the patient expired and an autopsy was requested by her family.

Histopathologic examination revealed diffuse polarizable crystalline deposits with numerous foreign body granulomatous changes involving both the native and transplanted lung due to diffuse microvascular pulmonary microemboli. The rodlike particle shape and size and birefringence with polarized light were consistent with microcrystalline cellulose. No evidence of acute inflammation or rejection was identified in the transplant lung. A review of numerous sequential transbronchial biopsies demonstrated foreign body type granulomatosis beginning three months following transplantation. The presence of microcrystalline cellulose in the lungs was highly suspicious of intravenous drug abuse despite a negative clinical history of abuse.

Intravenous drug abuse can cause numerous pulmonary complications including pulmonary granulomatosis and microemboli with severe respiratory compromise. Histopathologic examination is of paramount importance in determining cause of death in patients who reportedly have no history of drug abuse. This presentation discusses a case of serendipitous intravenous drug abuse in a lung transplant patient.

Lung Transplantation, Pulmonary Granulomatosis, Intravenous Drug Abuse

Pathology/Biology Section - 2015

H153 Death Scene Findings Associated With Accidental Toxicity Deaths in New Mexico, United States, From 2010 to 2011

*Timothy J. Dubois**, NM Office of the Medical Investigator, 1101 Camino de Salud NE, Albuquerque, NM 87102; *Sam W. Andrews, MD*, Office of Medical Investigator, 1101 Camino de Salud, NE, Albuquerque, NM 87102; and *Sarah Lathrop, DVM, PhD*, Office of the Medical Investigator, 1 University of New Mexico, MSC 07 4040, Albuquerque, NM 87131

After attending this presentation, attendees will be able to identify specific scene findings that are directly associated with accidental toxicity deaths in New Mexico. In addition, attendees will have a better understanding of changes and current trends in toxicity deaths using an evidence-based approach of more than 576 actual cases.

This presentation will impact the forensic science community by presenting an evidence-based methodology in determining likely overdose cases based on scene findings.

Understanding the specific markers of toxicity will allow medicolegal death investigators and other death scene responders to more easily triage potential overdose cases in sudden, non-violent deaths in adulthood.

In accidental overdose deaths, toxicology will always be considered the final arbiter; however, before toxicology testing can ultimately confirm or expose the toxic nature of a death, these cases need to be appropriately flagged and triaged into the medicolegal system. Medical examiners/coroners depend on initial information and scene findings to determine the level of medicolegal scrutiny that cases will receive. The quality of this information and appropriate understanding of the findings themselves are integral to the process that ultimately leads to these cases being autopsied and toxicology testing being performed. The overwhelming majority of this information will come from observations and interviews conducted on scene.

The objective of this study was to identify common death scene indicators and catalog potential markers for toxicity found on accidental overdose scenes. Death scene reports and scene investigations in 578 unintentional toxicity deaths over a two-year period (2010-2011) in New Mexico were systematically reviewed to identify scene indicators and document patterns suggestive of toxicity. More than half (54%) of the deaths were due to prescription drugs and 10% were attributed to a mixture of prescription and illicit drugs. Women represented more than half (53%) of the prescription overdose deaths, but only 17% of illicit overdose deaths. Decedents dying of a prescription drug overdose were significantly more likely to be White, non-Hispanics ($p < 0.0001$) and were also significantly older than people dying from illicit substance overdoses ($p = 0.01$). Almost one-third (31%) of prescription overdoses were in people more than 49 years of age. More than half (56%) of these decedents had three or more prescriptions for pain medication, and 55% had medications with counts not within expected limits, making access to medication slightly more prevalent than tangible evidence of misuse. Decedents were found in a position of sleep in fewer than half (46%) of prescription overdose deaths more than 49 years of age, and evidence of tampering with the scene was found in 9% of overdoses more than 49 years of age, which was greater than in cases 49 and younger (6.9%).

It was also determined that there was a significant incidence of history of potentially lethal natural disease in prescription toxicity deaths in older persons (67% for ages 50 and over). Thus, the presence of natural disease should not be solely used as a disqualifier for autopsy or toxicology testing. Even in cases with natural disease and little evidence of substance abuse, particularly in decedents more than 49 years of age, investigators must maintain a high index of suspicion for prescription overdose deaths if access to potentially abused medications is present.

The landscape of toxicity is rapidly evolving and understanding how toxicity deaths present themselves on scene provides an opportunity to refine the triage process using an evidence-based approach for future cases, both for death-scene investigators and pathologists. This presentation will assist death-scene investigators and pathologists alike in recognizing and understanding the association between specific scene findings and accidental toxicity.

Overdose, Accidental, Scene

Pathology/Biology Section - 2015

H154 **An Analysis of the Causal Relationship Between Maternal/Prenatal Cocaine Use and Stillbirth: Results of a National Hospital Database Study**

Frank A. Franklin, PhD, Forensic Research & Analysis, 425 NW 10th Avenue, Ste 306, Portland, OR 97209-3128; and Michael Freeman, MD, PhD, 425 NW 10th Avenue, Ste 306, Portland, OR 97209*

The goal of this presentation is to describe the contribution of maternal/prenatal cocaine exposure to stillbirth risk using national hospital data. After attending this presentation, attendees will better understand an issue increasingly encountered by medical examiner offices: whether maternal/prenatal cocaine exposure is a cause of stillbirth and, when such exposure is found in the instance of a stillbirth, whether the exposure can be ruled the sole cause of the stillbirth.

This presentation will impact the forensic science community, as well as those who represent disadvantaged populations, by elucidating the causal association between maternal/prenatal cocaine exposure and stillbirths.

Prenatal illicit substance use, including the use of crack cocaine, has become the focus of recent legislative attention in a number of states in recent years. In some states, the occurrence of a stillbirth coinciding with maternal and thus fetal exposure to cocaine, is considered evidence of homicide. Because stillbirth occurs both with and without maternal/prenatal cocaine exposure, it is fallacious to consider such exposure the entirety of the cause of a subsequent stillbirth without first considering the magnitude of competing causal factors. Without accurate information on cause, there is no way to determine the manner of death in a case of stillbirth following maternal/prenatal cocaine exposure (absent toxicology findings indicating a fatal dose).

Stillbirth, defined as a fetal death occurring at 20 or more weeks of gestation, is a relatively common adverse pregnancy outcome in the United States.¹ In 2005, a stillbirth rate 6.22 fetal deaths per 1,000 live births was reported in the United States, totaling 25,894 deaths.² Stillbirth occurs disproportionately among the disadvantaged and women of color.¹ Although the etiology of stillbirth in individual cases is often unclear, a number of associated factors, including poverty, single motherhood, inadequate prenatal care, maternal age, infection, obesity, diabetes, thrombophilia, fetal genetic or structural abnormalities, and umbilical cord abnormalities have been identified. Maternal syphilis infection is strongly associated with stillbirth, but it is a rare case; in 2008, there were 431 cases of congenital syphilis reported in the United States, of which only 25 (6%) were stillborn.³

The relationship between maternal cocaine exposure and stillbirth risk is incompletely explored at the present time. Using a case-control design Miller and colleagues examined stillbirths occurring at an urban hospital in Louisiana in 1994.⁴ That study reported the odds of stillbirth among the cocaine-exposed group as a non-significant 1.18 (95% CI 0.45, 5.07). In a later study linking birth and death certificates, Wolfe et al. reported a non-significant odds ratio of 1.2 (95% CI 0.99, 1.42) for fetal death and fetal cocaine exposure in the univariate analysis.⁵ A multivariate analysis that accounted for confounding variables demonstrated a counterintuitive protective effect (OR 0.2, 95% CI 0.19, 0.30). Flenady and colleagues reported a significant association between illicit drug use and stillbirth, but did not provide an analysis of cocaine use individually.⁶

Despite the fact that cocaine use during pregnancy is associated with adverse outcomes such as low birth weight, preterm birth, and small-for-gestational-age status, there are several issues that obscure the relationship between cocaine use and stillbirth.⁷ Polydrug use and socioeconomic factors make it challenging to distinguish the effects between cocaine and other socioeconomic, ethnic, and health factors commonly associated with cocaine use. Additionally, the presence and degree of maternal cocaine use is difficult to measure.

To further explore this relationship, an analysis of hospital inpatient birth data was performed. Data from the Nationwide Inpatient Sample Database (NIS) of the Healthcare Utilization Project of the Agency for Healthcare Research and Quality of the United States Department of Health was accessed. The NIS is a publicly held database containing data from approximately eight million United States hospital stays each year in 45 states, or approximately a 20% sample of all hospital discharges. The NIS data allow for a national estimate of the incidence, risk factors, outcomes, and other variables pertaining to all conditions seen in US hospitals. A univariate analysis of the contribution of maternal cocaine presence to stillbirth risk, along with other known risk factors, was conducted. These findings were used to construct an adjusted model of cocaine exposure as a cause of stillbirth, using binomial logistic regression.

The preliminary results of this analysis resulted in an odds ratio of 1.58 (95% CI 1.02, 2.45), equivalent to an attributable risk or probability of causation of 37%. Thus, the result of this preliminary analysis indicates that the presence of maternal/prenatal cocaine use in a case of stillbirth does not even account for more than 50% of the cause of the stillbirth. Further analysis is needed to examine the interaction of a wider variety of predictive factors.

Pathology/Biology Section - 2015

H155 Heroin Trends in Cuyahoga County, 2013

Claire Kaspar-Naso, BS, Cuyahoga County MEO, 11001 Cedar Avenue, Cleveland, OH 44106; Erin M. Worrell, BSc, 2551 Traymore Road, University Heights, OH 44118; Hugh Shannon, BS, Cuyahoga County MEO, 11001 Cedar Avenue, Cleveland, OH 44106; Camille Herby, MPH, Case Western Reserve University School of Public H, 11001 Cedar Avenue, Cleveland, OH 44106; and Thomas P. Gilson, MD, Cuyahoga County MEO, 11001 Cedar Avenue, Cleveland, OH 44106*

After attending this session, attendees will understand the emerging problem of heroin abuse and its relationship to prescription narcotic abuse. Attendees will gain an appreciation of significant risk factors for heroin overdose.

This presentation will impact the forensic science community by highlighting an emerging national epidemic of heroin abuse. By defining risk factors, public health interventions may be formulated. A model for data collection, analysis, and intervention planning is presented which may serve as a template for other communities experiencing this problem.

Heroin has been a cause of overdose fatalities for several years with intermittent cycles of increased popularity. Recently, abuse of Opioid Pain Relievers (OPR) has been linked to an alarming rise in mortality on a national level and several efforts have been made to address this problem. In Cuyahoga County, OH (metropolitan Cleveland), heroin mortality has re-emerged and overshadowed all illicit and legal drug-related fatalities, including OPR. In 2013, there were 194 overdose fatalities involving heroin, either alone or in combination with other drugs, representing approximately 60% of all overdose deaths.

Analysis of demographic data revealed that the majority of the deaths involved the White race (85%) and males (73%). The most common age group was 45-60 years of age (38%) and most victims were single or divorced (86%). Recent trends in the county have shown an increase in the percentage of women and younger addicts, each of which now represent approximately 25% of all deaths. There was a slight majority of suburban deaths (outside of Cleveland city proper), both in injury incident location as well as decedent residence. Approximately 12% of deaths were veterans of the armed services.

In early 2013, The Cuyahoga County Medical Examiner's Office convened a Poison Death Review Committee to prospectively review heroin fatalities in greater depth. This multidisciplinary committee includes members from medical and law enforcement/judicial communities sharing primary source information on a number of variables to provide data to inform policy decisions. These variables included whether the decedent was using drugs with others (12%), whether others were present but not using drugs when the decedent overdosed or proceeded through the terminal stages of intoxication (58%), whether first responders administered the opiate overdose antidote naloxone (28%), whether drug paraphernalia was present at the scene of death (53%), and whether the decedent had a previous history of illicit drug use (95%), especially intravenous drug abuse (62%). Review of recent decedent interactions with various systems revealed that within two years prior to death, 64% had received some type of medical treatment, 45% had some mental health history, 48% had received detoxification/rehabilitation services, and 40% had been incarcerated.

To explore the relationship between heroin mortality and prescription medications (including OPR), data from the Ohio Automated Rx Reporting System (OARRS), the Ohio prescription drug monitoring program was reviewed. OARRS data is limited to two years prior to the date of the search. The majority of Cuyahoga County heroin victims had a legal prescription for a controlled substance within two years of their fatal overdose (73%), with 65% having a prescribed opioid and 32% with a prescribed benzodiazepine. Of note, 36% of decedents met criteria for "doctor shopping," defined as five or more prescribers of controlled substances within a one-year period.

These data have been employed to support public health interventions in the county and indicate there are significant opportunities for educational efforts on several fronts to address this epidemic.

H156 **Obstruction of Aqueduct of Sylvius Following Spontaneous Intra-Ventricular Hemorrhage and Meningitis in a Premature Infant Leading to Hydrocephalus and Cystic Cerebellar Degeneration With Polymicrogyria: A Case Study With a Review of Literature**

*Avneesh Gupta, MD**, 1300 E Warren Avenue, Detroit, MI 48207; *Amanda O. Fisher-Hubbard, MD*, 1640 Weatherstone Drive, Ann Arbor, MI 48108; *Jeffrey Hudson, MD*, University of Michigan/Wayne County MEO, 1300 E Warren, Detroit, MI 48207; *Kilak Kesha, MD*, Wayne County MEO, 1300 E Warren Avenue, Detroit, MI 488207; and *Carl J. Schmidt, MD*, Wayne County MEO, 1300 Warren, Detroit, MI 48207

After attending this presentation, attendees will better understand the etiology, pathological findings, genetic associations, clinical features, and forensic presentations of blockage of the aqueduct of Sylvius.

This presentation will impact the forensic science community by raising awareness regarding distant complications and the long-term outcomes of spontaneous intra-ventricular hemorrhage and blockage of the aqueduct of Sylvius.

The aqueduct of Sylvius is the narrowest part of the ventricular system and its obstruction leads to hydrocephalus (dilatation of the lateral ventricles of brain). Obstruction of the aqueduct is usually associated with sporadic stenosis, atresia associated with Arnold-Chiari malformation, gliosis following infection or hemorrhage, vascular malformation, or X-linked hydrocephalus spectrum. A review of the literature led to rare case reports of gliosis related to various infectious etiologies including mumps, toxoplasmosis, tuberculosis, parasitic granuloma, and aspergillus.

A case is reported of a premature eight-month-old girl who developed hydrocephalus and cystic cerebellar degeneration due to obstruction of the aqueduct of Sylvius following the development of spontaneous intra-ventricular hemorrhage and meningitis. The infant was born at 24-weeks gestation by spontaneous vaginal delivery and was 860 grams at the time of delivery. The pregnancy was complicated by chorioamnionitis. The early clinical course of the infant was significant for *Streptococcus agalactiae* and *Escherichia coli* sepsis, meningitis, and Grade III intra-ventricular hemorrhage with placement of an intra-ventricular shunt. Her family at home cared for her and she required tube feeds for nutrition. Early one morning, her mother checked on her and found her apneic. She was pronounced dead on arrival at the hospital. An autopsy revealed no external or internal evidence of injury. There was bilateral acute pneumonia. The brain weight was 387 grams (normal adjusted brain weight=516 grams). The cerebral cortex appeared atrophic and the cerebral hemispheres showed polymicrogyria. On cut surface, there was yellow discoloration of the periventricular white matter. There was obstruction of the aqueduct of Sylvius with dilation of the lateral and third ventricles and cystic degeneration of the cerebellum. Microscopic examination revealed gliosis and hemosiderin-laden macrophages within the periventricular white matter and adjacent to the aqueduct of Sylvius. The cause of death was certified as pneumonia and hydrocephalus as complications of prematurity.

Aqueduct of Sylvius, Blockage, Hydrocephalus

II Medicolegal and Criminological Suicide Diagnosis in Historical Cases: A New Methodology

*Luca Massaro, MD**, via degli Artigiani n° 4 ESTE (PD), Este (PD) 35042, ITALY; and *Matteo Borrini, PhD*, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM

After attending this presentation, attendees will be informed about a new method for the medicolegal and criminological diagnosis of suicide based on five empirical and statistical criteria.

This presentation will impact the forensic science community by proposing how the application of five different criteria for suicide diagnosis can also be useful and reliable for the investigation of both historic and cold cases, taking into account the incompleteness of the evidence.

The forensic practice clearly demonstrates that a predominant number of suicides have typical or frequent distinctive characteristics (i.e., common wound topography in the case of firearm injuries by short- or long-barrelled weapons); however, some suicides show atypical or unusual features (i.e., multiple gunshot wounds or incomplete hanging). According to the International Association for Suicide Prevention (IASP), in 2013, the number of suicides worldwide was estimated to be one million; this number raises the urgency to provide crime scene operators (prosecutors, police officers, investigators, pathologists, and forensic anthropologists) with an investigative technique that allows them to recognize and distinguish suicide from other manners of death with a high degree of scientific probability.

This presentation proposes the application of a new combination of criteria to emblematic historical cases.¹ This new method, based on analyses of Italian case reports, can be summarized by the answers to five different questions, as evaluated by a specific scoring system: (1) did the victim use a suicide method frequently observed during that specific era and in the nation/culture of origin?; (2) are the method and injuries compatible with suicide?; (3) was a singular or multiple method used?; (4) is evidence from the environment and crime scene consistent with suicide?; and, (5) are there any indications of psychiatric disorder in the victim's medical history?

Since ancient times and across almost all cultures, suicide has been a widespread practice, even though some communities do not seem to acknowledge self-inflicted death, at least from a statistical standpoint. Nevertheless, even a minimal investigation of suspicious/equivocal/undetermined death is virtually unknown throughout antiquity. For this reason and to test the applicability and limitations of the five criteria, three cases were selected: Judas Iscariot, Antonius and Cleopatra, and Vincent Van Gogh. The selection has been oriented toward well-known characters from different socio-cultural contexts and epochs to tackle the issue of suicide without prejudice.

As result, the test confirms the potential in applying the five diagnostic criteria in historical cases as well to better understand distant epochs and episodes. Consequently, this study demonstrates how this approach also became relevant and useful in the investigation of cold cases with active forensic interest; however, in this scenario, it is essential to have as much data as possible to permit a scientifically valid examination of all aspects describing the case. To confirm this last assumption, the example of Van Gogh is meaningful. In Van Gogh's case, the availability of circumstantial information related to suicide and anamnestic information derived from the painter's letters to his brother make the manner of death effectively clear and understandable.

This study will present a new approach for the investigation of doubtful manners of death with the emphasis on addressing the relevance of each singular aspect of the methodology in different scenarios.

I2 Malingering Detection With the Autobiographical Implicit Association Test

Laura Muscatello*, Via I.spallanzani 9 albinea, Reggio Emilia, ITALY; and Annabella A. Pozzoli, MEd*, via Milano, 3, Lentate sul Seveso, ITALY

After attending this presentation, attendees will be familiar with one of the most popular tests in Italy used to establish whether an autobiographical memory trace is encoded in the respondent's mind.

This presentation will impact the forensic science community by increasing awareness of a new test that can be used in a forensic setting to establish if the respondent is lying and if the fact that the respondent says he/she does not remember is in his/her implicit memory.

A new method that can be used to identify a true autobiographical memory (intentions and reasons that motivate an act) is the autobiographical Implicit Association Test (aIAT).¹ It is a variant of the Implicit Association Test that is used to establish whether an autobiographical memory trace is encoded in the respondent's mind/brain.²

With the aIAT, it is possible to evaluate which of two autobiographical events is true. The method consists of a computerized categorization task that is structured in five blocks; three simple blocks (1, 2, 4) and two combined categorization blocks (3 and 5). In simple blocks, each response button is used to classify sentences related to only one category. In double blocks, each response button is used to classify sentences related to two different categories.

In Block 1, participants have to classify true and false sentences (e.g., I am in front of a computer vs. I am in front of a television) using two response keys, one on the left and one on the right of the keyboard. In Block 2, participants have to classify autobiographical sentences (e.g., I went to Paris for Christmas vs. I went to New York for Christmas) with the same two response keys. In Block 3 (double categorization block), true sentences and sentences related to the first autobiographical event (e.g., Christmas in Paris) are paired on the same response key and false sentences and sentences related to the second autobiographical event (e.g., Christmas in New York) are classified with the other response key. In Block 4, only autobiographical events are reversely classified with the two response keys. Finally, in Block 5, participants have to classify both true sentences and sentences related to the second autobiographical event (Christmas in New York) with the same response key, and false sentences and the first autobiographical event (Christmas in Paris) with the other key.³

The true autobiographical event is identified because, in a combined block, it gives rise to faster Reaction Times (RT's) when it shares the same motor response with true sentences. Validation experiments have documented very high classification accuracy over a wide range of tests, with average accuracy rates exceeding 90%. The aIAT has been validated both in forensic and in clinical settings. In this study, the aIAT main applications (it distinguishes between witnessed and non-witnessed detail, detection of intentions, detection of Reasons Underlying Lies, malingered whiplash syndrome, malingered depression, etc.) are reviewed and one of the most popular cases in which it has been used in Italy is presented: The Case of Como.³

I3 Criminal Behavior and Single Nucleotide Polymorphisms in Genes Related to Dopamine and Serotonin Modulation

Gabriella Cansino, BS, 2209 Bobby K Marks Drive, Apt 55, Huntsville, TX 77340; Peyton Gandy, MSFS, 2052 Myrtle, Unit 3, Dover, DE 19901; Jessica A. Motl, MS, 4312 Homestead Circle, San Angelo, TX 76905; Todd Armstrong, PhD, Sam Houston State University, College of Criminal Justice, 816 17th Street, Huntsville, TX 77320; Matt R. Nobles, PhD, Sam Houston State University, College of Criminal Justice, PO Box 2296, Huntsville, TX 77341-2296; Brian Boutwell, PhD, Sam Houston State University, College of Criminal Justice, 816 17th Street, Huntsville, TX 77320; and David A. Gangitano, PhD, 13906 Paradise Valley Drive, Houston, TX 77069*

After attending this presentation, attendees will understand how principles of behavioral genetics can be applied to investigate antisocial or criminal behavior.

This presentation will impact the forensic science community by providing a better understanding of the manner in which certain genes related to modulation of neurotransmitters influence criminal behavior.

Little is known about the biological mechanism that regulates antisocial behavior; however, a number of dopamine-related genes have been implicated in the etiology of violent behavior and conduct problems. These genes include Monoamine Oxidase A (MAOA), Monoamine Oxidase B (MAOB), Catechol-*O*-Methyl-Transferase (COMT), Dopamine Beta-Hydroxylase (D β H), and Tryptophan Hydroxylase 1 (TPH1). A landmark study in molecular genetics reported that individuals with low-functioning alleles within the MAOA gene were more likely to develop antisocial behavior following maltreatment. Although the literature concerning behavioral genetics is accumulating, there is limited information concerning the neurobiological mechanisms influencing criminal behavior in humans

The focus of this research is to investigate polymorphisms in genes associated with dopamine and serotonin modulation in an incarcerated population and a control group. This study investigated 13 single nucleotide polymorphisms (SNPs) in five genes involved with dopamine and serotonin regulation. The following SNPs were selected: rs909525, rs3788862, rs979605 (MAOA), rs1799836, rs2283729 (MAOB), rs740603, rs737865, rs165599, rs4680 (COMT), rs739398, rs1611115, rs129882 (D β H), and rs1800532 (TPH1).

DNA was extracted from buccal swabs collected from male inmates incarcerated in a southern Texas jail (N=100) and from control male students (N=93). All the protocols used in this study were approved by the Institutional Review Board at Sam Houston State University. DNA was quantified by real-time Polymerase Chain Reaction (PCR) and samples were amplified and subjected to single base extension. Extended products were detected by capillary electrophoresis with fluorescent detection.

After correction for multiple comparisons, departures from Hardy-Weinberg equilibrium were not observed in any group. Linkage disequilibrium was strong in MAOA and COMT genes ($D' > 0.8$), moderate in MAOB ($D' = 0.65$) and weak in D β H ($D' = 0.30$). Although no single genetic variant in any of the five genes differentiated individuals in the investigated groups, significant haplotype differentiation ($p < 0.05$) was observed for MAOA, MAOB, and COMT markers.

Moreover, gene-gene interaction was identified between MAOA rs3788862-rs979605, COMT rs165599-rs740603, and COMT rs4680-D β H rs739398.

This evidence suggests that defined haplotypes and Single Nucleotide Polymorphism-Single Nucleotide Polymorphism (SNP-SNP) interactions in MAOA, MAOB, and COMT SNPs are associated with criminal behavior. Overall, the study attempts to understand the biological basis of complex behaviors, such as antisocial and criminal behaviors, by identifying relevant genes and promoting future research on the genetic influence on criminal behavior.

Behavioral Genetics, Criminal Behavior, Single Nucleotide Polymorphism

I4 Forensic Analysis of a Chiropractor Accused of Sexual Assaults on His Patients: A Case Report

Jutta M. Birkhoff, MD, PhD, Via O. Rossi, Varese 21100, ITALY; Giuseppe O. Armocida, MD, University of Insubria, Via O. Rossi 9, Varese 21100, ITALY; Laura Re, MD, Via Guicciardini 9 Bis, Varese 21100, ITALY; Davide Torri, MD, Via O. Rossi 9, Padiglione Antonini, Varese 21100, ITALY; and Antonio M. Osculati, MD, Via Meraviglia 22, Lainate, Milan 20020, ITALY*

After attending this presentation, attendees will be able to discuss how to approach a psychiatric evaluation of a subject with paraphilic sexual behavior and unspecified personality disorder.

This presentation will impact the forensic science community by providing a discussion of the reasons why the subject was not considered mentally insane at the time he committed the crime.

This presentation concerns a psychiatric-forensic assessment of a health care expert, a chiropractor, accused of having drugged and raped a large number of male patients. These criminal actions went unnoticed for many years until he made an error in medicating a patient, who awoke while being manipulated by the chiropractor. Newspapers and television programs described the subject as a very aggressive, violent serial sex offender. The local population characterized him as a “monster” and some people also took violent action against him and his properties by, for example, setting his house on fire. When the man’s criminal behavior was discovered, he was accused of repeated sexual assaults and the judge requested an evaluation of the subject’s state of mind at the time the crime was committed.

The goal of this presentation is to describe how examiners approached such a case and the results of the forensic psychiatric assessment. It was discovered that criminal sexual intercourse as described above was the only type of sexual relationships the subject had during his life. The evaluation also revealed that the subject did not develop a mature sexual identity and wasn’t able to properly indicate his sexual preferences. Despite his being accused of rape, he described his intercourse with his victims in terms of genital manipulation, without penetration. He also took numerous pictures of his patients while they were naked and drugged. The subject’s criminal behavior was very organized and appeared not to be simply instinctual. In fact, his crimes were discovered because he finally committed an error and one of his patients woke up while being raped.

Trying to analyze the subject’s psychic functioning model, the examiners discovered a disorder of sexual preference, with enduring unusual sexual needs and activities; however, none of the criteria for a specific paraphilia were identified, so the subject was considered to have an unspecified sexual preference disorder with problems in sexual development and orientation. The forensic psychiatric assessment also revealed the coexistence of an unspecified personality disorder. Answering the judge’s requests, the examiners considered that the accused’s criminal actions, which quite clearly represented symptoms of the subject’s disorder, could not be regarded as a sign of an unconsciously manageable pathological impulsiveness.

Sexual Offender, Paraphilia, Personality Disorder

I5 Aggression and Interpersonal Violence in Hospital Emergency Departments

Adam H. Crighton, BS, 4650 Waterford Circle, Stow, OH 44224; Scott Bresler, PhD, UC Medical Center, Division of Forensic Psychiatry, 260 Stetson Street, Box 670559, Cincinnati, OH 45219; Dustin B. Wygant, PhD, 521 Lancaster Avenue, 127 Cammack, Richmond, KY 40475; and Gordon L. Gillespie, PhD, University of Cincinnati, PO Box 210038, Cincinnati, OH 45221-0038*

After attending this presentation, attendees will be aware that hospital-based Emergency Departments (EDs) rank among the most dangerous working environments in the country. Attendees will gain an understanding of the association between chief clinical complaints (reasons for hospital visit) and specific types of aggression (i.e., verbal or physical assault).

This presentation will impact the forensic science community by offering insight into underlying causes of aggression via differentiating between physical violence and verbal assaults/threats, thereby increasing the competence of those working in hospital settings.

Given the high prevalence of violence in ED settings, it may be useful to examine the association between the types of chief clinical complaints that bring a patient into the hospital and the nature of ensuing aggression with the purpose of identifying potential risk factors for violence. The current study examines the association between specific types of aggressive incidents (i.e., verbal or physical) and chief complaints voiced in an emergency department setting.

Physical violence and verbal incidents from six EDs were recorded and compiled into a large dataset ($N=813$). Each incident was classified for the presence of verbal threat/assault and various types of physical aggression (e.g., hitting, spitting, kicking, pushing). A count variable was calculated based on the number of aggressive incidents per patient. Medical staff (e.g., physicians and nurses) provided a qualitative appraisal of the cause/underlying nature of the aggressive incident. These data were then classified into various broad categories that included, among others, intellectual disability, mental illness, neurological issues (e.g., head injury), medication issues, drug/alcohol intoxication, mental status changes (e.g., dementia, psychosis), suicidal ideation, homicidal ideation, frustration with wait time at the ED, refusal to leave the ED, and pain symptoms.

Point-biserial correlations were calculated to examine the association between the number of aggressive incidents per patient and each of the broad categories describing the medical staff's explanation of the incident. Small, but significant, positive correlations were found between the presence of intellectual disability and incidents of aggression ($r=.103, p<.005$), as well as presence of homicidal ideation ($r=.104, p<.005$). Pain symptoms were negatively correlated with overall level of aggression ($r=-.090, p<.05$).

Chi-square analyses were calculated to examine the association between verbal vs. physical aggression and each of the broad categories used to explain the incident. Patients rated as having intellectual disability ($\chi^2=4.77, p<.05$), neurological issues ($\chi^2=4.40, p<.05$), changes in mental status ($\chi^2=4.14, p<.05$), and homicidal ideation ($\chi^2=6.02, p<.05$) were significantly more likely to exhibit physical vs. verbal aggression. Patients with pain symptoms ($\chi^2=5.16, p<.05$) and those who experienced frustration due to wait time ($\chi^2=10.32, p=.001$) were significantly more likely to exhibit verbal vs. physical aggression.

In summary, the presence of intellectual disability and homicidal ideation were associated with a greater number of aggressive incidents per patient, whereas pain symptoms were associated with fewer aggressive incidents. Several factors were also able to significantly discriminate between verbal and physical features of aggression. For instance, intellectual disability, neurological issues, changes in mental status, and homicidal ideation were associated with physical aggression, whereas pain symptoms and frustration due to wait times were associated with verbal aggression. Although pain symptoms were related to lower levels of overall aggression, they were nevertheless related to higher levels of verbal vs. physical aggression. These results have implications for risk assessment in medical settings.

Violence, Threats, Risk Assessment

Psychiatry & Behavioral Science Section - 2015

I6 Could Cases of Abusive Head Trauma (Shaken Baby Syndrome) Historically Have Been Misdiagnosed as Pervasive Developmental Disorders?

Michael J. McCarthy, BA*, Eastern Virginia Medical School, School of Health, 651 Colley Avenue, Norfolk, VA 23507; Catherine B. Pearman, MPAS, Eastern Virginia Medical School, School of Health P, 651 Colley Avenue, Norfolk, VA 23507; and Wendy M. Gunther, MD, OCME, Tidewater District, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510-1046

The goals of this presentation are to: (1) review original cases used to establish the diagnosis of Childhood Disintegrative Disorder (CDD) (Heller syndrome); (2) compare overlap of symptoms of CDD with those of abusive head trauma (shaken baby syndrome); (3) consider whether CDD and other Pervasive Developmental Disorders (PDDs) may have historically included missed cases of abusive head trauma; (4) evaluate whether or not it is possible to distinguish symptoms of abusive head trauma in children with the use of the new criteria of Autistic Spectrum Disorder in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5); and, (5) examine whether child evaluators using DSM-5 receive enough training to distinguish abusive head trauma symptoms from Autistic Spectrum Disorders (subsuming CDD and other pervasive development disorders).

This presentation will impact the forensic science community by informing attendees of the possible overlap between pervasive developmental disorders and abusive head trauma since the origin of the diagnosis in historical literature was used to formulate the criteria before the recognition of child abuse.

PDD, a diagnosis established in the first part of the 20th century, may subsume unrecognized cases of abusive head trauma (shaken baby syndrome) if providers utilizing the DSM-5 are not trained in the recognition of child abuse.¹

PDDs are characterized by serious and persistent impairment in several areas of development, which are described as occurring after initially normal development. The same can be said for some cases of abusive head trauma (also known as shaken baby syndrome, shaken-slam syndrome, or inflicted traumatic brain injury). Despite overlap in their symptomology and presentation, disorders that have most recently been classified in the DSM-5 as Autistic Spectrum Disorders were first described and labeled decades before abusive head trauma was a regularly considered differential for medical diagnosis.

Review of the historical cases used to establish and describe PDD, in particular CDD, was undertaken to determine whether methods used were sufficient to rule out loss of developmental milestones from inflicted head trauma and, in particular, whether providers without medical training in child abuse will be able to differentiate the two when utilizing the DSM-5 to make diagnoses.^{2,3}

Writers and researchers who developed the DSM-5 now believe a single umbrella of Autistic Spectrum Disorders will improve the diagnosis of PDDs without limiting the sensitivity of the criteria or substantially changing the number of children diagnosed. If the criteria are based on historical cases that may have included missed cases of child abuse, psychologists and other evaluators undergoing training in the diagnosis of Autistic Spectrum Disorder may not be equipped to separate symptoms of abusive head trauma in infants and young children from late-developing autistic spectrum disorders. Recognition of this issue may aid in preventing misdiagnosis of future cases of inflicted head trauma as Autistic Spectrum Disorders.

I7 Assessment of Children Who Are in Conflict With the Law: Çukurova University Department of Child and Adolescent Psychiatry Between 2006 and 2011

Kemal C. Yildirim, MD, Çukurova University School of Medicine, Dept of Forensic Medicine, Balcali, Adana 01330, TURKEY; Aysegül Y. Tahiroglu, MD, Çukurova University, Dept of Child and Adolescent Psychiatry, Adana, TURKEY; Kenan Kaya, Çukurova University, Faculty of Medicine, Dept of Forensic Medicine, Adana, Saricam 01330, TURKEY; Necmi Cekin, MD, Çukurova University School of Medicine, Dept of Forensic Medicine, Balcali, Adana 01330, TURKEY; and Mete K. Gulmen, PhD, MD, Çukurova University, School of Medicine, Dept of Forensic Medicine, Adana, 01330, TURKEY*

After attending this presentation, attendees will better understand the data relating to the sociodemographic characteristics of children driven to crime, their mental health, and the crimes allegedly committed.

This presentation will impact the forensic science community by providing information about the attention given to upcoming policies developed to protect children.

According to international law, 18 years of age is considered to be the age of maturity and consent. Children grow up both physically and mentally and need care, education, and protection from outside influences during this phase.

Juvenile delinquency can be described as illegal behavior by children. The child who is having a hard time adapting to rapidly changing phases during puberty can commit illegal acts because of social inexperience. A child may not realize the act is a crime or that the crime will affect his/her future life. Legally the term “delinquent child” was favored over “criminal child/child who has committed a crime.”

Doctors are asked to determine if the delinquent child has a criminal responsibility. The primary questions to analyze are whether the child was mentally competent to understand the meaning of the action, had reached a mentally developed stage to understand the results of his/her actions, and understood what shaped his/her behaviors.

In this study, 141 case reports were retrospectively evaluated. This study included 134 boys (95%) and seven girls (5%) with an average age of 13.6+1 for girls and 13.1+1.1 for boys. In terms of education, 76 of the 141 cases were continuing their education, 65 cases were not continuing their education, five cases had no education, and eight cases continued their studies in a private educational institution. Fifty-six cases (39.7%) indicated their mothers had no education, 56 cases (39.7%) indicated their mothers graduated from primary school, 20 cases (14.2%) indicated their fathers had no education, and 71 cases (50.4%) indicated their fathers graduated from primary school. The average number of siblings was 4.2+2.6, and there were 13 siblings at most in one case. Both parents were alive in 131 of 141 cases (92.9%); there wasn't sufficient information for this determination in four cases (2.8%). Forty cases (28.4%) had a history of neglect in some area and 27 of these cases (19.1%) had a history of neglect in more than one area. When analyzed according to areas of neglect, 25 (17.7%) education cases, 27 (19.1%) discipline and social needs cases, 19 (13.5%) sanitation-care/nutrition cases, and 20 (14.2%) health cases were reported. There were 49 cases reporting violence in the family (34.8%) with nine of them (6.4%) reporting violence between parents. When the alleged crimes were analyzed, there were 50 cases (35.5%) of robbery, followed by 25 cases (17.7%) of sexual abuse. Crimes against life were more common with girls, while crimes against property, terror crimes, and sex crimes were more common with boys.

In childhood, the features of criminal acts are strongly affected by gender differences. Boys have an increased likelihood of acting more severely and engaging in personal forms of criminal behavior.¹ From 12 to 15 years of age, the lack of self-control is more important than perception; in most situations, it is known that children are unable to shape their behaviors as the law necessitates.²

It should be taken under consideration that if a child continues his/her education in an educational institution, that child will be less likely to engage in criminal behavior as he/she will not be in a criminal environment.^{3,4} Looking for happiness in another place is natural for a child who has a bad family environment; inevitably, the child is also looking for attention in a criminal environment.⁵ If a child took part in a crime, punishment is not a recommended method of prevention. Criminal law must be the last process to use with these children.

The people who will either enhance or diminish the future are the children of today. For a better future, it is our social and public duty to ensure physical, mental, social, and cultural development for our children.

I8 Violence in the Inpatient Psychiatric Unit: A Case Study and Review of the Literature

*Varma Penumetcha**, 20620 Kensington Court, Apt 202, Southfield, MI 48076; and *William Cardasis, MD*, 2723 S State Street, Ste 150, Ann Arbor, MI 48104

After attending this presentation, attendees will understand the multitude of factors predisposing inpatients for violent and aggressive behavior, including the role played by the surroundings and staff in mitigating or inciting such behavior. Emphasis will be given to the incident that is being investigated for this case study while signifying the role of the inpatient psychiatrist and support staff, once such an incident happens.

This presentation will impact the forensic science community and inpatient psychiatrists by clarifying the roles of individuals as part of a multidisciplinary team when faced with a violent incident involving grievous injury in an inpatient setting. The review of literature on this subject could prove instrumental in being able to anticipate such incidents and take necessary precautions to foster a safe environment for patients and staff.

Violent incidents are common in inpatient psychiatric units compared to lower levels of care. They constitute a major hazard for both the staff and the patients and tend to be unpredictable. The factors influencing these incidents are often deduced by their post-hoc analysis.¹ Although male and female patients carry a close relative risk of perpetrating such events, the majority of incidents with severe bodily injuries or fatalities involve a male patient being the assaulter.² This presentation will discuss a female patient who assaulted a male patient, resulting in significant bodily injury, and the sequence of events that ensued. The predetermined role of hospital personnel in handling such incidents will be discussed. A summary of the review of literature on this subject will also be presented.³

The specific goals of this case report and review of the literature are to: (1) deduce the patient-, surrounding-, and staff-related factors identified from previous studies of aggression and violence in inpatient psychiatric units, which are specifically pertinent to the case under discussion; (2) propose an approach for documenting such incidents as part of a registry to be available for analysis and determination of specific factors responsible in a hospital or an institution. This could prove instrumental in devising specific interventions necessary to create a predictable environment for psychiatrists and a safe environment for patients; and, (3) propose that this data be used in the post hoc analysis of such events in order to understand nuances of environmental and staff factors specific to the community hospital at which these incidents took place. The factors that will be focused on are the timing of the shift changes, experience of the staff, diagnosis of the patient's involved, voluntary/involuntary admission, day of the week, time of the day, and a history of similar incidents in the past based on the available records. Identifying these factors before data collection will prevent any biases and will ensure a uniform sample for analysis.²

19 Violent Behavior and Protective Factors: A Retrospective Study of a Psychiatric Patient's Cohort in Southern Italy

*Felice F. Carabellese, MD**, University of Bari, Section of Forensic Psychiatry, p.za G. Cesare, 11, Bari 70124, ITALY; *Gabriele Rocca, Via De Toni 12, Genoa, ITALY*; *Chiara Candelli, MD, PhD, Section of Criminology and Forensic Psychiatry, p.za G. Cesare, Bari 70124, ITALY*; *Donatella La Tegola, PhD, p.za G. Cesare, 11, Bari 70124, ITALY*; *Domenico Montalbò, MD, p.za G. Cesare, 11, Bari 70124, ITALY*; and *Roberto Catanesi, MD, p.za G. Cesare, Bari 70124, ITALY*

After attending this presentation, attendees will focus on possible psychosocial factors that may be specifically associated with the various modalities of violent behaviors enacted by the sample cohort examined (directed against others, directed against objects, and self-directed) in order to identify targeted strategies of prevention and treatment.

This presentation will impact the forensic science community by assessing the role of psychosocial factors in the etiology of violent behavior.

In recent years, numerous investigations have confirmed that patients suffering from severe mental illness are at greater risk of engaging in violent behavior. Several risk factors that increase the probability of psychiatric patients committing violent acts have been identified. Some of the factors associated with violent behavior are also psychosocial, including: the occurrence of stressful events, belonging to a “pathogenic” or “disinterested” family, a family history of substance abuse and violent behavior, and poverty and deprivation of the family of origin. There is evidence in the literature to suggest that some psychosocial factors exert a protective effect.

Method: The four different public psychiatric outpatient facilities taken into consideration met all the same criteria of homogeneity. In addition, the local social service agencies in each municipality were involved in the investigation. The sample consisted of 1,582 subjects. The resulting data were stored in a dedicated database. Psychosocial factors and various modalities of violent behavior were the main focus in the sample.

Results: Most patients had long clinical histories (70% of the cases had more than 10 years of history) and had often been hospitalized (sometimes forcibly) over the years. The most common diagnosis was mood disorder (41.2%). After the first contact with the facility, virtually all patients were placed on psychopharmacological treatment (84%).

Violent behavior emerged in the clinical histories of more than one-third (36.3%) of the patients in this sample. Males were clearly predominant among patients exhibiting violent behavior (65.74%). In the majority of cases, this behavior was directed exclusively toward others (76.7%). There was a significant correlation between violent behavior and a family history of either substance abuse or violent behavior. In approximately half of these cases, the victim of the violence was one of the parents.

One episode of violent behavior toward other persons was recorded in 27.9% of the total sample. For the most part, this behavior was enacted by men (69%). Indeed, male sex proved to be a risk factor for violent behavior toward others. Having a supportive family reduced the likelihood of enacting violence against others. By contrast, this probability was increased by the presence of a disinterested family or a “pathogenic” family. Good intra-familial relationships were seen to reduce the probability of committing acts of violence against others, while poor intra-familial relationships increased this probability. Likewise, the probability of engaging in violence against others was reduced when extra-familial relationships were good or satisfactory. By contrast, poor extra-familial relationships increased the likelihood of violence against others. Having a good psychosocial level was seen to reduce the probability of engaging in violence against others as was a satisfactory psychosocial level.

Discussion: Generally speaking, a significant prevalence of violent behavior emerged in this sample, especially among more seriously ill psychiatric patients (psychotic disorders). Moreover, as this study unequivocally demonstrates, the phenomenon investigated is, in terms of magnitude and gravity, considerable. This first finding, which has a direct and immediate impact, requires consideration in order to draft adequate treatment programs.

The importance of psychosocial protective factors is therefore confirmed. In agreement with the literature data, this study confirmed the general finding that protective factors play a significant role in preventing the enactment of violent behavior.

Psychiatry & Behavioral Science Section - 2015

Apart from the results yielded by the present research, many of which are in agreement with the literature, some of the limits typical of a retrospective study must be taken into account, in particular the partial nature of the medical documentation available. Moreover, episodes of violent behavior on the part of patients in public health service care are not always reported in clinical records. It therefore seems likely that the phenomenon was underestimated in the population sample studied.

Mental Illness, Violent Behavior, Protective Factors

I10 The Acute Stress Response to Threats and Physical and/or Verbal Aggressions: The Influence of Epigenetics on Defensive Strategies of Human Behavior

Luca Massaro, MD*, via degli Artigiani n° 4 ESTE (PD), Este (PD) 35042, ITALY; Patrizia Trapella, JD*, via Cavour 24, Rovigo, ITALY; and Vincenzo Lusa, JD*, Via Ferdinando, Palasciano #72, Rome 00151, ITALY

After attending this presentation, attendees will be informed about current perceptions of epigenetics on the issue of human capacity/ability to react to a threat.

This presentation will impact the forensic science community by reviewing the results of many important works concerning the acute stress response to threats in the hope that studies on the pairing of fear and epigenetics may shed more light on this subject.

It is a known fact that the behavioral responses — primordial and animal responses — to a dangerous stimulus are diversified among individuals as well as among subjects of varied age and gender.

In particular, the defensive (animal) forms of behavior are shown to be integrated within a complex and flexible mechanism which is distance-dependent (Eilam) — it is known that human behavior is organized in modules that are relatively independent from one another (Tooby and Cosmides).^{1,2}

Over the years, Cannon's intuition (fight or flight) about the mechanism of human behavioral response to threat, Marks' behavioral sequence (flight, freeze, fight, and appeasement), Gray's sequence (freeze, flight, fight) as studied in animals and non-human primates, the theory of Gray and McNaughton (clear distinction between fear and anxiety), and the variant thereof put forward by Bracha (freeze, flight, fight, fright) have been reviewed and studied.

However, why does a subject take to flight in the face of an aggression while another individual will fight? Why is it that one woman runs away while another reacts by putting up a fight? Why does one child freeze when confronted with a dangerous situation while another flees? Why does a particular individual, when placed in front of the same threats, fight at one moment (or stage) of his life while at a different moment he escapes or, given the same scenario, he first escapes and then fights? The differences depend on a multiplicity of factors. (i.e., age, bio-social-genetic characteristics of the victims, etc.).

But how, for the sake of the survival strategy, does the environmental variability (Levins and theory of evolution in a fluctuating environment) interact with the genes?

The study of epigenetics may show how gene changes occur in accordance with the type of environment in which the individual finds himself interacting; for instance, "ill-treating environment" or "beneficial environment." A genetic variability is produced, one on which the evolutionary factors are capable of acting by molding the individuals' adaptation capacity; thereby, empowering the suited phenotypes to self-reproduce and be transmitted across generations. Simultaneously, the same mechanism prevents the unsuited phenotypes from gaining ascendancy, with a resultant decrease in the genotypes lying at the base. Notwithstanding that, studies carried out in the last decades have proven that the genomic variations are not merely "casual" but also "causal" (i.e., they are induced by the environmental impact, or better still, guided by whatever surrounds the organism (natural and social habitat)).

The suggested study hypothesis is as follows: in order to attain deep knowledge of all the aspects relating to acute response to a noxious (dangerous/lethal) stimulus as well as if and how such reaction is going to change in the future, one must be profoundly acquainted with the mechanism of fear, the way it is memorized, and the mechanism of decision making through epigenetics. Thus, one could understand the real assessment a human subject makes in response to external stimuli; value may be assigned to such a response with a view to exempting the subject from legal accountability in the event of a criminal trial against him/her.

Epigenetics, Fear, Threats

Psychiatry & Behavioral Science Section - 2015

II1 Mental Health Services Within California's Prison Realignment Act (Assembly Bill 109): Challenges and Recommendations

Cynthia Chavira, MD, PO Box 86125, Los Angeles, CA 90086-0125; Timothy Botello, MD, University of South California, Institute of Psychiatry & Law, PO Box 86125, Los Angeles, CA 90086-0125; and Isabel Lagomasino, MD, University of Southern California, Dept of Psychiatry & Behavioral Sciences, 2250 Alcazar Street, Ste 2200, Los Angeles, CA 90033*

After attending this presentation, attendees will be familiar with: (1) the legal background that led to the development of California's Assembly Bill (AB) 109, implemented October 2011; (2) the mental health services provided under AB109 in Los Angeles County; and, (3) the potential challenges faced by AB109 probationers in terms of accessing mental health treatment in Los Angeles County.

This presentation will impact the forensic science community by raising awareness of the barriers to accessing mental health services under AB109 and by identifying potential solutions to improving access and thereby decreasing recidivism.

AB109, commonly referred to as "realignment," came as a result of two major class action lawsuits in California: *Coleman v. Brown* in 1990 and *Plata v. Brown* in 2001, in which the United States Supreme Court ruled that inadequate medical and mental healthcare in California state prisons was a violation of inmates' eighth amendment rights protecting them from cruel and unusual punishment. These deficiencies were attributed to state prison overcrowding and the United States Supreme Court ordered California to reduce the number of its prison inmates by 33,000 within two years. The state of California responded by enacting new legislation, AB109, which overall resulted in the transfer of responsibility of low-level offenders from the state to local counties. AB109 resulted in three major changes in the California criminal justice system: (1) individuals convicted of non-serious, non-violent, non-sexual crimes now serve time in county jail rather than state prison, even if the sentence length is longer than one year, as long as they do not have any prior serious or violent convictions; (2) parole violators are sent to county jail rather than to state prison; and, (3) if the most recent offense was non-serious, non-violent, and non-sexual, then the offender released from state prison is placed on county probation (post-release community supervision) rather than state parole, regardless of prior convictions, which may be serious, violent, and/or sexual.

AB109 legislation has major implications for mentally ill probationers. It is estimated that nearly 30% of California prison inmates suffer from mental illness, and the recidivism rate is higher among offenders with mental illness, as compared to those without mental illness. Since the passage of AB109, more than 18,000 former state prisoners are now under Los Angeles County probation supervision, and approximately 8,000 are in Los Angeles County's Department of Mental Health database because of a history of mental illness. It should be noted that AB109 does not mandate that counties provide re-entry programs that offer rehabilitation; also, the allocation of funding to rehabilitation is left to the discretion of each individual county. Given the high prevalence of mental illness in California prisons, the question becomes whether local counties will be able to adequately fund rehabilitation programs to meet the needs of this at-risk, mentally ill offender population. AB109 could potentially be part of the solution to decreasing the "revolving door" of recidivism; however, this will depend on post-release mental health services and accessibility.

This presentation will include case examples that illustrate some of the challenges faced by AB109 probationers in terms of accessing mental health treatment. The presentation will include information obtained from individual semi-structured interviews with mentally ill patients on AB109 probation, regarding their mental health history, legal history, post-release mental health treatment course, and outcomes. Information from interviews with staff at a Los Angeles mental health treatment program for AB109 probationers will also be presented to demonstrate the perspective of treatment providers on the challenges and facilitators to providing mental health services to this population. In order to conduct the study, approval was obtained by the University of Southern California Institutional Review Board. Finally, recommendations will be made for ways to potentially improve the delivery of mental health services to this unique population.

I12 Stalking of Health and Social Services Workers: Preliminary Results of a Study Conducted by the Region of Apulia, Italy

Ignazio Grattagliano, MD, University of Bari, Piazza Cagnola, 3/B, Casamassima, Bari 70010, ITALY; Grazia Pierri, PsyD, University of Bari, Piazza Giulio Cesare, Bari 70124, ITALY; Adriana Pastore, MD, University of Bari, Piazza Giulio Cesare, Bari 70124, ITALY; and Francesco Margari, MD, p.za G. Cesare, Bari 70124, ITALY*

After attending this presentation, attendees will be more aware of the impact that stalking of healthcare professionals has on workers in the helping professions.

This presentation will impact the forensic science community by demonstrating that further, well-designed studies are needed in order to confront this underestimated but very serious problem facing healthcare professionals.

The helping professions, which include those disciplines whose workers' goals are to help others (e.g., general physicians, psychiatrists, psychologists, educators, and social workers) all have one criminologically relevant feature in common: a high risk for being the target of stalking.

A study conducted by Galeazzi, Elkins, and Curci has shown that out of 108 psychiatrists, psychologists, and graduate students, 20% were the target of some sort of stalking for a period of one month or longer, with more than ten single episodes of intrusion.¹ According to this study, the incidence of stalking in the helping professions may be attributed to a series of reasons. For example, the professional may become a "good" or "bad" person in the eyes of the client, and based on such fantasies, this can give rise to "troubling and disturbing" behaviors on the part of the patient who seeks to attract the attention of the professional with the hope of never being separated from him or her. Professionals in the field of social work, psychology, and psychiatry come to know the most intimate needs of their clients; consequently, they can easily become the object of the patient's projections, affections, and fantasies of all types to such an extent that gratitude may be progressively transformed into a desire for an affective or friendly bond that they cannot do without.

Patients who harass their therapists are inclined to mistake a purely professional relationship for a personal one. Feeling the frustration that arises from this expectation, they may begin to act out intrusive behaviors in order to establish contact. In such situations, the relationship boundaries imposed by the professional are breached. A patient may begin to telephone repeatedly, send letters, and show up at the professional's office without an appointment claiming that they are not understood and that they are being treated badly. Other contributing factors to such situations may include errors, deficiencies, and limitations on the part of the helping professional in establishing and creating a proper setting for their patients. When there is a lack of clear-cut professional rules (e.g., excessive intimacy, closeness with the patient and his family, an absence of well-defined boundaries within the professional relationship, and requests by the worker to become more personally involved), the creation of communicative distortions and very real misunderstandings, which can be the trigger for stalking behavior, may emerge.

This study was carried out in both the public and private sectors of health and social services facilities in the region of Apulia, Italy, both in the public and private sectors. All workers at the Psychiatry and Child Neuropsychiatry Units at the Policlinic of Bari, as well as all other workers in private social services facilities that are affiliated with the national healthcare system, were interviewed. Adult consumers of these facilities include those with psychosocial problems, physical disabilities, victims of all types of violence, and those who suffer from psychological dependence. All of the subjects in this study were given a 20-question, multiple-choice questionnaire to be completed individually and anonymously. Sociodemographic data on both victims and presumed perpetrators of harassment, along with the circumstances surrounding the events, and the victims' emotional reactions were collected via this questionnaire on a sample of 101 subjects, all of whom were professionals in the field of social and healthcare services (i.e., medical doctors, psychologists, nurses, and social healthcare workers), in both the public and private sectors.

The subjects in this study who reported harassment attributable to the crime of stalking are represented as n=30 subjects out of n=101 of the total sample (29.7%). Females are more highly represented with F=22/30 (73.3%) with respect to males (M=8/30 (27.6%). With regard to women workers, 30.14% of them (22/73) reported having endured some type of harassment and 28.7% of male workers (8/28) reported the same.

The data derived from this study reveal that little attention is paid to this phenomenon and that the victims of harassment in this study tend to have little faith in the institutions where they work addressing these concerns. Other factors that play a role in these events include a health and social services system that, when it comes to stalking, its prevention, and how to best deal with it, is rather outdated. Only a small part of these crimes (16.1%) is reported to the authorities or anti-violence centers.

Psychiatry & Behavioral Science Section - 2015

This study highlights that there is a significant lack of information available regarding the phenomenon of stalking and its psychological repercussions on workers who encounter it. After having conducted this study, the necessity for training that informs health and social services workers, both in the private and public sectors, about the most suitable ways of avoiding and/or confronting stalking, has become even more evident.

Cesare, Bari 70124, ITALY

After attending this presentation, attendees will better understand the extremely rare phenomenon of parricide and many of its implications.

This presentation will impact the forensic science community by demonstrating that further, well-designed studies are needed in order to confront this underestimated but very serious problem facing families.

Parricide is a very rare phenomenon and represents only a small percentage of all homicides committed. In Europe and the United States, it is estimated that the occurrence of this crime makes up between 2% and 4% of all murders in those regions, with patricides outnumbering matricides.¹⁻⁷ In Italy, the 2008 European Employment Services-Agenzia Nazionale Stampa Associata (EURES-ANSA) Report observed that the rate of parricide in Italy makes up 3% of all homicides committed, with the rate of matricide being significantly higher (59%) than patricide.

Homicide occurs more frequently in homes where the victim and perpetrator cohabit.^{8,9} When a minor commits parricide, he or she does so in a cold and calculated manner and does so in such a way as to avoid confrontation with the victim; for example, when the parent is sleeping, watching television, or engaged in some other activity.¹⁰ Parricide is rarely committed during a violent altercation between parent and child.

Males are much more likely to commit parricide.¹¹⁻¹⁶ For example, when Marleau et al. investigated parricide cases committed in Canada between 1961 and 1989, they observed that males committed 90% of these killings.¹⁷ A vast majority of the literature regarding young perpetrators of parricide shows that minors kill in order to bring years of abuse to an end. Other factors that may influence this phenomenon have also been identified, in particular, the presence of psychiatric disorders and the antisocial tendencies of minors.^{18,19} These seem to be important aspects in the implementation of this crime. Based upon this, it is possible to identify three categories of juvenile perpetrators of parricide: (1) adolescents who suffer from serious mental pathologies; (2) antisocial adolescents; and, (3) adolescents who have endured severe abuse and who kill as a reaction to their circumstances.²⁰ Minors who are systematically punished, criticized, treated with hostile rejection, or ignored by their primary caregivers tend to believe that they are at fault, unwanted, bad, or unlovable.²¹ Such global and negative beliefs about oneself elicit shame because, when shame is experienced, the sense of self is threatened and attention is focused internally.²² In this way, minors who have been or who are currently being treated in a punitive manner seem to develop a different disposition regarding the emotion of shame and their reactions to other life events when compared to those minors who have not been maltreated. For example, Alessandri and Lewis pointed out that maltreated minors (i.e., neglected; physically, sexually, and emotionally abused), from 4-5 years of age, exhibit much more shame when they make a mistake and show less pride when they do well with respect to their non-maltreated peers.²³

Lack of affection, brutality, various forms of violence, and coercion coming from one or both parents may be elements that facilitate the formation of highly discordant and unrestrained personality structures. Furthermore, the presence of a generation gap may be unbridgeable in more serious situations. This is characterized by reciprocal incomprehension and an absence of clear and direct forms of communication regarding central aspects of relational life. In addition, one fact that this study would particularly like to underscore relates to the presence of emotional imbalances and alterations that may act to compromise the formation of a mature self that is endowed with healthy sensitivity and the capacity to foresee the consequences of one's own actions as well as those of others. For this reason, it is necessary to view parricide as a process that is comprised of precipitating risk factors that need to be identified early on, both at the clinical level and at the criminological and forensic psychiatric level as well, in an attempt to avoid tragic and irreversible "acting out."

I14 Elder Abuse: Risk Factors and the Role of the Nurse

Graziamaria Corbi, PhD, via Giovanni Paolo II-Loc Tappino, Campobasso 86100, ITALY; Ignazio Grattagliano, MD, University of Bari, Piazza Cagnola, 3/B, Casamassima, Bari 70010, ITALY; Nicola Ferrara, MD, via Giovanni Paolo II-Loc Tappino, Campobasso 86100, ITALY; and Carlo P. Campobasso, MD, PhD, University of Molise, Dept Medicine & Health Science, via De Sanctis, snc, Campobasso 86100, ITALY*

After attending this presentation, attendees will better understand the very serious and under-reported crime of elder abuse.

This presentation will impact the forensic science community by demonstrating that further, well-designed studies are needed in order to confront and more fully comprehend this problem facing our aging population.

Currently, elderly people are more active, independent, and likely to be in good health in addition to having a longer life expectancy than in the past. In spite of this, abuse, exploitation, and abandonment of the elderly still remains a hidden and underestimated problem throughout the world. Often the people responsible for these abuses are the victims' relatives or, in cases where the victim resides in some sort of institution or facility, the abusers are often the healthcare workers themselves. Abuse affects the physical and psychological well-being of the aged and may lead to a serious public health problem. From the available data regarding the elderly in Europe, the World Health Organization (WHO) has disclosed that in 2004, about four million people over 60 years of age experienced physical abuse; one million experienced some form of sexual abuse; six million were the victims of financial abuse, and a solid 29 million endured psychological abuse; however, such statistics do not accurately reflect the problem. Often, attention is paid to this phenomenon only when news of medical malpractice is reported by the mass media that tend to report only a part of the overall problem, thus leading to incorrect and inadequate conclusions regarding healthcare workers and the general nature of the phenomenon.

Goal of the Study: Beginning with these assumptions, the goal of this study is to examine the available literature in order to define the role of the nurse regarding elder abuse, focusing on the possible types of abuse perpetrated, the possible reasons for such, and possible preventive interventions.

Materials and Methods: Articles regarding elder abuse taken from international literature from the last five years were selected. This study was carried out using well-known scientific databases such as PubMed®, The Cochrane Library, MEDLINE®, EMBASE®, Medscape, and www.clinicaltrials.gov. The WHO and The National Center for Elder Abuse (NCEA) websites were also used. The following key words were entered into each database: "elder abuse," "elder mistreatment," "abuse and neglect of the elderly," and "elder abuse in nursing homes."

Results: Most scientific studies that deal with the abuse and exploitation of the elderly have been published in the PubMed® databases, whereas in other scientifically recognized sources such studies are relatively scarce. Nevertheless, on the WHO and NCEA websites, this topic is recognized as a serious problem and demonstrates the need for more well-designed and analytical studies in order to improve the approach to this phenomenon. Research into this issue is still lacking even though there has been an increase in published studies on the topic in recent years. Summarizing the data that has emerged from PubMed® regarding elder abuse and utilizing specific key words, it has been deduced that in the last five years approximately 750 articles have been published. These findings have been divided into subcategories and shown in Table 1.

Table1: Distribution of scientific articles on elder abuse in various databases

	PubMed®	Cochrane Library	Medscape
Elder abuse	460	3	4
Elder abuse in nursing homes	60	0	0
Elder mistreatment	80	0	1
Abuse and neglect in elderly	150	0	2

Psychiatry & Behavioral Science Section - 2015

Conclusions: Analysis of the selected scientific literature shows that the problem of elder abuse is progressively increasing as the population ages. Scientific articles on the subject are relatively scarce and the vast majority of these studies are quite recent, having been published in the past ten years. Though there may be a general misperception of this phenomenon, one that points the finger of elder abuse at healthcare workers, the truth is that most instances of elder abuse happen within the family environment, and even to this day speaking about it is considered to be a real taboo. The studies examined provide some indications that may be utilized in confronting the problem of elder abuse by acting on risk factors and swaying public opinion toward the recognition of the existence of this problem, which in turn could help in developing more effective programs through well-designed research studies.

Elder Abuse, Role of Nurses, Aging Population

I15 Qualitative Analysis on the Ability to Provide Consent of Treatment to Patients With Chronic Neurodegenerative Diseases — Alzheimer's Disease

*Felice F. Carabellese, MD**, University of Bari, Section of Forensic Psychiatry, p.za G. Cesare, 11, Bari 70124, ITALY; *Antonio Leo, MD*, p.za G. Cesare, 11, Bari 70124, ITALY; *Donatella La Tegola, PhD*, p.za G. Cesare, 11, Bari 70124, ITALY; *Chiara Candelli, MD, PhD*, Section of Criminology and Forensic Psychiatry, p.za G. Cesare, Bari 70124, ITALY; *Salvatore Distaso, MD*, Section of Forensic Psychiatry, p.za G. Cesare, 11, Bari 70124, ITALY; *Alessandro Dell'Erba, PhD*, Risk Management Unit, Policlinico Teaching Hospital of Bari, Piazza Giulio Cesare 11, Bari 70124, ITALY; *Giancarlo Logroscino, MD, PhD*, p.za G. Cesare, 11, Bari 70124, ITALY; and *Roberto Catanesi, MD*, p.za G. Cesare, Bari 70124, ITALY

After attending this presentation, attendees will recognize characteristics in the use of “off-label” medical treatments in neurocognitive disorders.

This presentation will impact the forensic science community by increasing awareness of the competence of patients with neurocognitive disorders to consent to off-label use of atypical antipsychotic drugs.

In neurocognitive disorders, psychotic symptoms and behavioral dysfunctions are common and atypical antipsychotic drugs are considered, at the moment, preferred treatments; however, in Italy their use in patients (including older adults) with behavioral abnormalities is considered off-label. In Italy, off-label medical treatments are regulated by Law No. 94/98 which authorizes their prescription only after the obtainment of the patient's written informed consent. As is commonly known, informed consent is an essential prerequisite for any treatment. A valid consent may be given, in accordance with the ethical and legal standards of good clinical practice, only after a patient has received adequate information and included their health condition, the risks and benefits of the therapies proposed, possible alternatives have been evaluated, and their intact decision-making capacity (“competence”) has been verified. Informed consent is usually in oral or written form, as provided in the recent Italian Code of Medical Ethics (Article 35), in the case of off-label treatments.¹

The ISTAT (National Institute of Statistics) 2009 data show there is a progressive increase in the number of patients affected by dementia. The most common dementias are among neurocognitive disorders; in this context in recent years, new criteria has been developed for the clinical diagnosis that took into account the findings of research and a better understanding of the neuro-pathological disease.² The typical pathological lesions of Alzheimer's disease can be found in cognitively normal subjects, in those who present with Mild Cognitive Impairment (MCI), or in people with full-blown dementia. In these patients, where the risks associated with the recommended treatment are especially high, it is necessary to document the actual will of the person to accept the proposal of the doctor, as in the case of off-label treatments in behavioral disorders. Evidence in the literature suggests that even patients affected by severe chronic degenerative diseases still possess valid levels of competence to make some or all of the decisions about their treatment and thus no state of incompetence should be simply presumed.^{3,4} Patients regarded as legally competent to make their own decisions may not be able to completely understand the medical proposals and choices in order to make a truly valid decision and give aware consent. Even the recent Code of Medical Ethics (Article 33) expressly provides information concerning “understandable and comprehensive” therapy. Accordingly, the view is that the failure to give consent must be considered a priori not related to a mental illness, a particular diagnosis, or nosological category; it must be assessed on a case-by-case basis and go beyond the stage of the progression of the deficit and regard the possible impact of the disease on neurocognitive skills that are the basis of decision making. This is to ensure compliance with the rules of law and ethics, but also to provide ethical access to care by all patients in accordance with “freedom of care.”

For this reason, formats for adult persons and Parents/Guardian Ad Litem/Custodian/Administrative Support for interdicted or incapacitated beneficiary were designed. In the forms, scientific evidence of efficacy and the safety of proposed off-label treatment reported in the literature are explained. This important work fills a gap in the implementation of bioethical principles in the clinical setting.

I16 An Unusual Patricide: The Woman Who Dismembered Her Father

Felice F. Carabellese, MD, University of Bari, Section of Forensic Psychiatry, p.za G. Cesare, 11, Bari 70124, ITALY; Rosa Taratufolo, MD, p.za G. Cesare, Bari 70124, ITALY; Roberto Catanesi, MD, p.za G. Cesare, Bari 70124, ITALY; Isabella Aquila, MD, Viale Europa, località Germaneto, Policlinico Universitario, S Venuta-Medicina Legale, Catanzaro 88100, ITALY; Ciro Di Nunzio, MFS, PhD, Magna Graecia University, Viale Europa, Germaneto, Legal Medicine, Catanzaro 88100, ITALY; Francesco Ausania, MD, Largo Francesco Vito 1, Rome, ITALY; Walter Caruso, MD, Viale Europa, 88100 Catanzaro, Catanzaro, ITALY; and Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will have a better understanding of patricide.

This presentation will impact the forensic science community by discussing patricides. In this case study of patricide, the victim, a father, was killed by his child. In general, the murderer often suffers from mental illness and the homicide usually takes place in the home. In Italy, patricide is a rarely reported murder (about 3%) with the typical offender being a young, unemployed male who lives with the victim.

As an elderly man had been missing for about a month, his apartment was searched by the police. They found seven boxes containing body segments, covered by feminine clothing, surrounded by lime, and covered with cellophane. There was no blood or larvae present. The man's daughter said it was the corpse of a stranger and claimed not to have reported the discovery for fear of being accused of murder. She added that her father had been away from home and she did not know where he was. A postmortem computed tomography examination of the decedent showed multiple fractures of the head, inflicted by an object with a cutting edge. During the autopsy, the body was identified and the presence of nine dissected body segments was revealed. The right side of the skull was damaged and there was leakage of a completely liquefied brain. The soft tissues were removed through maceration techniques and chemical treatment to highlight the bones' margins in order to determine the weapon used, which was found at the crime scene, and the manner of death. The macroscopic analysis of bone margins with radiological and histological studies helped to assess the force of the injuries. The examination of the injuries inflicted on the head indicated the trauma occurred while the subject was still alive. An autopsy confirmed that the victim was the daughter's 72-year-old father. His 38-year-old daughter had been a medical school student and for years lived in another city where she attended the university. She suffered from psychiatric disorders and was not treated with drugs. After the death of her mother, she returned to live with her father. The daughter was arrested, but for months continued to deny that she killed her father. Finally, she wrote a letter to the judge in which she confessed to the murder.

The court ordered a forensic psychiatric assessment, against the advice of the attorney who was suspicious of the fact that the woman would possibly inherit her father's large estate. The prosecutor pointed out the woman's shortcomings in an attempt to prevent her from inheriting family property; however, experts concluded that at the time of the crime, the woman was suffering from schizophrenic disorders and was not guilty by reason of insanity. The woman had been told by her mother, who died about a year prior, that she and her husband were members of a satanic cult and that all members of this sect abused her from the time she was two to three years of age. She added that she had no recollection of any abuse because the sect members administered drugs that rendered her unconscious. The abuse took place only at night; by day, her parents led an exemplary life. After the death of the mother, the father had demanded they have sex, but she resisted, at which point, the father threatened to kill her. In the course of yet another clash with her father, where he attempted to rape her, the woman defended herself and finally struck him on the head with a heavy glass object. She then decided to cut the body into pieces in order to transport the remains and bury them more easily. In fact, the judge said she did not intend to make her pay for a crime committed as a defense against her father's abuse. The woman, who had claimed to have never had a romantic relationship, was not a virgin.

I17 Profiling in Violent Crimes: The Perpetrator and the Victim in Portuguese Cases of Filicide

Fatima Almeida, MSc, Centre of Forensic Sciences, Faculdade de Medicina, Rua Larga, Coimbra 3004-504, PORTUGAL; and Duarte N. Vieira, PhD, MD, Rua Antonio Jose de Almeida, No 117, Coimbra 3000-044, PORTUGAL*

After attending this presentation, attendees will understand how filicide, the murder of a child by a parent, is a multifaceted phenomenon with various causes and characteristics.

This presentation will impact the forensic science community by highlighting the present state of knowledge regarding filicide perpetrated by either the mother or father.

Goal: The goal of this study is to describe the homicide of children in Portugal and to examine the gender differences in filicidal offense characteristics and associated variables in order to establish a common profile of filicidal offenders and victims. Limitations of the current study and future directions for research will be presented.

Methods: This retrospective study was approved by the Ethics Committee from the Faculty of Medicine of the University of Coimbra and the National Institute of Legal Medicine and Forensic Sciences (NILMFS). The material of the present study was register-based, comprehensive, and nationwide. The information concerning all deaths certified as homicide or with an undetermined/unknown cause in 29 Portuguese medicolegal and forensic offices, for children under 18 years of age, for the period 2004-2013 was examined. Forty-two cases of filicide were analyzed with the Statistical Package for the Social Sciences (SPSS) 19.0 statistical software package. The assessed variables related to the perpetrator included demographic characteristics (e.g., age, sex, ancestry, marital status, and residence area). The assessed variables related to the victim included age, sex, ancestry, circumstances of birth, and number of victims. The variables related to the crime were correlated with the sex of the perpetrator (e.g., crime type, method, motive, post-offense behavior, suicide, and moment of the crime).

Results: A total of 39 perpetrators (six fathers and 33 mothers) killed 42 child victims (21 were male and 21 were female). Statistically significant differences were found between the sex of the perpetrator and the post-offense behavior ($r=.383$), the method ($r=-.323$), and the circumstances of the birth of the child ($r=.394$) to a level of significance of 0.05.

Conclusions: Most of the crimes were committed by young, unmarried Caucasian females between 21 and 30 years of age. The victims were mostly newborns ($n=17$) in non-hospital settings ($n=16$) and resulted from unintended pregnancies. Neonaticide was the most predominant crime with the use of manual and impersonal methods (i.e., fall, suffocation, drowning, strangulation, and intoxication). Males were older, married or divorced, who killed using more violent methods (i.e., firearms and knives) for revenge or retaliation against their companions. Their victims were also older. A better understanding of potentially fatal parental/familial dynamics leading to filicide could facilitate the identification of risk and enable effective intervention strategies.

Acknowledgements: This study wishes to thank all medicolegal and forensic offices of the Portuguese NILMFS for their cooperation and for having made this research possible.

Profiling, Filicide, Infanticide

Psychiatry & Behavioral Science Section - 2015

I18 Death Due to Neglect in the Elderly: A Sad Reality

*Isabella Aquila, MD**, Viale Europa, località Germaneto, Policlinico Universitario, S Venuta-Medicina Legale, Catanzaro 88100, ITALY; *Fiorella Caputo, MD*, Chair of Legal Medicine, Viale Europa Loc. Germaneto 88100 cz, Catanzaro, ITALY; *Silvia Boca, Viale Europa, Catanzaro, ITALY*; *Salvatore Savastano, Viale Europa, 88100 Germaneto, Catanzaro 88100, ITALY*; and *Pietrantonio Ricci, Viale Europa-Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will be able to describe the impact of forensic science in cases of abandoned elderly people.

This presentation will impact the forensic science community by demonstrating the crucial role of social and familial relationships in cases of neglect in the elderly.

In Italy, there are about 12 million people older than 65 years of age. With the continuous rise of life expectancy, the number of elderly citizens is steadily increasing.

A great number of older people live at home alone and many of them are completely abandoned despite poor medical conditions. Thus, it is very common for elderly people to die alone in their homes not having received medical assistance. Frequently, the discovery of the bodies may be several days after death. No one notices their disappearance and the alert is given late, often by neighbors. Consequently, many of the bodies are in an advanced state of decomposition.

At autopsy, the most frequent causes of death are represented by domestic accidents or cardiovascular disease such as myocardial infarction, ictus, or pulmonary embolism. Many of the deaths would be avoidable with an early warning and a timely rescue.

The reports of the autopsies performed at the Institute of Forensic Medicine of Catanzaro were analyzed and the cases of 20 patients who died between 2013 and 2014 were selected. All cases were of elderly people (nursing home patients with nervous system diseases and mental health issues) who were found dead in their own homes or in rural areas after they disappeared from the care facilities. For each case, the following was carried out using the psychological autopsy method: an inspection of records, an autopsy, and an investigation into a family member. Data analysis has highlighted that in every death, the body showed obvious phenomena of putrefaction. In addition, the autopsies revealed that the causes of death were: from cardiac origin (50%), from asphyxia (esophageal food bolus obstruction) (30%), from traumatic causes (15%), and from malnutrition (5%). The background data indicated a complicated family situation in which the elderly person usually lived alone and was not controlled by the family or by the staff of the nursing home in which he was bedridden. For this reason, it was concluded that the data collected during the judicial inspection and those shown by the medical, legal, and psychological autopsy revealed a deep state of abandonment of the elder before death as well as social and family loneliness. Such cases allow the conclusion that there is a real death-by-neglect in the elderly. Therefore, it emphasizes the importance of family and social integration of the population between 60 and 80 years of age in order to: (1) prevent fatal events related to the lack of prevention of curable diseases which, in a state of neglect, are not treated; (2) avoid accidental events related to lack of control of older people with mental disorders and central nervous system patients at nursing homes or hospitals; (3) increase control strategies in nursing homes or hospitals for the mentally ill or for elderly patients with neurological diseases; and, (4) increase levels of social and family integration distributed throughout cities and towns. These incentives will reduce the exponential increase in deaths from neglect in the elderly.

Forensic Science, Elderly, Neglect

I19 Critique of New Sex Offender Management in California: Assessment, Containment, and Treatment

Susie Morris, MD, USC Institute of Psychiatry and Law, PO Box 86125, Los Angeles, CA 90086-0125*

After attending this presentation, attendees will have an understanding of the sociopolitical history predicated current sex offender evaluation, treatment, and supervision rationale in the state of California. Attendees will also gain a basic understanding of the “containment model,” the codified model for sex offender management in California since 2012, and the roles of therapists, law enforcement, and polygraph examiners within that model. Attendees will be able to: (1) assess the evidence for and against California’s model for sex offender management; (2) draw conclusions about the efficacy of the model; and, (3) consider what further information is needed to bolster the system’s ability to reduce sex offender recidivism, provide adequate supervision, facilitate safe community re-entry, and furnish ethical mental health care to the sex offender.

This presentation will impact the forensic science community by: (1) generating ideas regarding areas where more research is needed with respect to sex offender risk assessment; and, (2) developing novel approaches to improve the current model in sex offender treatment, management, and community re-integration.

In 2008, a state-appointed task force evaluated California’s methods for management, treatment, and registration of sex offenders. This report, prepared jointly by the California Coalition Against Sexual Assault and the California Sex Offender Management Board, indicated areas for improvement in state management of sex offenders. Deficient areas cited were: (1) lack of specific accountability of government agencies with respect to assessing recidivism risk; (2) absence of data on recidivism of sex offenders within the state; (3) inadequate numbers of treatment providers for both incarcerated and non-incarcerated sex offenders; and, (4) no codified guidelines for either risk assessment or treatment of sex offenders. Following this report, Penal Code (Section 290-294) was amended, establishing the State-Authorized Risk Assessment Tool for Sex Offenders (SARATSO) Review and Training Committee.

The SARATSO committee’s function is to select risk assessment instruments to be employed by trained professionals to assess the individual risk of sex offenders with respect to re-offense. This information is meant to be provided to law enforcement and the judiciary in formulating appropriate sentencing, deciding upon post-incarceration supervision (parole or probation), recommending treatment programs, and evaluating the progress of the offender (via observation of assessment score patterns). The ideal assessment tool should reliably predict re-offense risk, accurately assess static and dynamic risk factors, and demonstrate good inter-rater reliability. Currently, the Static-99 and the Juvenile Sexual Offence Recidivism Risk Assessment Tool-II (JSORRAT-II) are the recommended assessment tools for adult male and juvenile male offenders, respectively.

A discussion of how the adult assessment tool scores impact treatment, placement, and community integration will be presented. A critical analysis of California’s sex offender management will be provided from the vantage point of the mental health care provider, and conclusions will be drawn regarding both the merits and potential deficiencies of the containment model within California. The goal will be to generate ideas regarding areas where more research is needed. In addition, with the goals of balancing community safety and providing the sex offender with effective mental health treatment, novel approaches to improve the current model will be posited.

Sex Offense, Recidivism, Risk Assessment

Psychiatry & Behavioral Science Section - 2015

I20 Evaluation of Sexual Abuse Crimes Committed By Teachers Against Students in Terms of Socio-Demographic Characteristics and Related Parameters

*Fatih Yagmur**, Adli Tip Kurumu Cobancesme, Istanbul, TURKEY; *Mustafa Çeltek, MD*, Adli Tip Kurumu, Çobançesme Mah. Sanayi Cad. Kimiz Sok. No 1, Bahçelievler, Istanbul 34180, TURKEY; *Taha Yasin Arslan*, Council Of Forensic Medicine, Yenibosna Çobançesme, Mah.Sanayi Cad. Kimiz Sok. No: 1, Istanbul 34196, TURKEY; *Hüseyin Keles*, Adli Tip Kurumu Çobançesme Istanbul, Istanbul, TURKEY; *Alperen Bıkmazer*, Council of Forensic Medicine, Istanbul, TURKEY; and *Harun Akkaya, MD*, T.R. Ministry of Justice, Forensic Science Dept Headquarters, Istanbul 34100, TURKEY

The goal of this presentation is to protect school-age children. Guided by the results of this study, it will be possible to plan treatment for child victims and implement social support mechanisms.

This presentation will impact the forensic science community by increasing awareness concerning unanticipated suspects in sexual abuse crimes.

Introduction: Sexual crime against children, committed by teachers responsible for their education and care, is the main topic in this study. Such crimes are severe social problems and suspects are teachers who are trusted by children and their families. Evaluation of the suspects and the victims separately makes this study unique.

Material and Method: In 2013, the forensic investigation files of the sexual abuse victims came from different regions of Turkey to the Specialization Council of the Istanbul Forensic Medicine Institute, which specializes in forensic psychiatry and sexual crimes, and were evaluated retrospectively. Cases involving educators as suspects were included in the study. Socio-demographic variables such as local regions, ages of the victims and suspects, type of school (public or private), sex differences, and multiple victim situations were evaluated. Mental levels and detailed psychiatric examinations of victims and the types and experiences of suspect teachers were also evaluated. Statistical Package for the Social Sciences (SPSS) 15.0 was used for statistical analysis.

Results: In 2013, 6,310 cases were evaluated in the Specialization Council of the Istanbul Forensic Medicine Institute. These cases are composed of child and adult sexual assault victims, juveniles driven to crime, and other sexual crime cases. One hundred thirty-four of these cases involved children abused by a teacher or educator. Two hundred two children were abused in 134 cases. One hundred eighty-one (89.6 %) were girls and 21 (10.4%) were boys. In 166 (82.17 %) of these cases, the crime was simple sexual abuse (such as touching, kissing, verbal abuse, etc.) and in 36 (17.83%) of the cases, the crime was qualified sexual abuse (such as sexual assault with penetration or ejaculation). The average age of the victims was 11.36 years of age and the majority (113) of victims (55.94%) were in primary and secondary school (first- through eighth-grade students). Ten victims' parents were divorced, 182 had normal mental capacity, 11 demonstrated low average Intelligence Quotient (IQ) scores, five had mild mental retardation, and four had moderate mental retardation. It was detected that seven victims attempted suicide after abuse. Due to the Turkish Criminal Code, psychiatric evaluations reported if there was impairment in mental health as a result of sexual abuse. According to the psychiatric evaluations, 17 (8.41%) of the victims were reported to have impairment in mental health, and 31 (15.34%) were reported to have no impairment detected in their mental health; however, the rest of the victims were reported to have some deterioration in mental health because of sexual abuse.

In terms of the perpetrators: 66 (98.50%) of the 67 suspected teachers were male, with an average age of 41.37 years; 47 of the teachers had been teaching more than ten years; 42 of the teachers worked in public school, while 24 worked in private school; one was an unknown employee; 20 (29.85%) were class teachers, 12 (17.91%) were math teachers, seven (10.44%) were physical education teachers, and eight (11.94%) were managerial. It was found that 30 (44.77%) of the teachers had abused more than one child.

Discussion and Conclusion: There are few worldwide studies in literature examining both sexual crime victims and perpetrators. The goal of this study is to protect school-age children. As a result of this study, planning victim children's treatment and social support mechanisms will be facilitated.

Istanbul Forensic Medicine, Sexual Abuse, Teachers

Psychiatry & Behavioral Science Section - 2015

I21 Assessment and Treatment of Problematic Sexual Behaviors: An Update

*J. Paul Fedoroff, MD**, Royal Ottawa Hospital, 1145 Carling Avenue, Ottawa, ON K1Z 7K4, CANADA; and *R. Gregg Dwyer, MD, EdD**, Medical University of South Carolina, Community & Public Safety Psychiatry Division, 29-C Leinbach Drive, Charleston, SC 29407

The goal of this presentation is to provide an update on the latest evidence-based approaches to assessment and treatment of adults with problematic sexual behaviors.

This presentation will impact the forensic science community by updating attendees on the evidence-based approaches to assessment and treatment of problematic sexual behaviors for practical application. In addition, it will ideally serve as an interactive method for the collection and exchange of methods and ideas among forensic professionals in the furtherance of developing a standardized guide with a wide consensus.

Although there are common recommendations for the content and methods of assessing and treating persons who have engaged in sexually offensive behavior, there is no universal standard or practice parameter. National and international associations have promulgated guidelines in the past, but not all who are engaged in assessment and treatment are members of such organizations; even among those who are, not all follow the recommendations. Consequently, practitioners and members of the legal community recommending, receiving recommendations for, and overseeing risk management activities are left with minimal, at times inadequate, and even conflicting guidance.

This presentation is presented by forensic practitioners who have experience with clinical, research, and educational facets of both assessment and treatment. This study will provide content that is evidence-based and in keeping with health care and forensic evaluation ethical standards. At the completion of this presentation, attendees will be provided an overview as well as the foundation to be able to: (1) identify the goals of assessing adults with sexual problems/offending behaviors; (2) identify components of comprehensive adult sexual problems/offending behavior assessments; (3) discuss strengths and weaknesses of assessment methods; (4) identify treatment targets; (5) develop a basic treatment plan addressing the application of both psychological and biological interventions; and, (6) discuss efficacy of various interventions and their respective strengths and shortcomings. Clinical, psychometric, and physiological assessment methods will be addressed to include penile plethysmography and polygraphy. For the treatment component, medication management will be included with attention given to use of antiandrogens and antigonadotropics for management of paraphilic symptoms. This presentation is intended to give behavioral science practitioners an overview of the tools available and procedures for their use in assessing and treating problematic sexual behaviors. Additionally, conducting this presentation interactively will serve as a means to elicit input from other forensic professionals in attendance as to their methods of conducting assessments and providing treatment to a unique population as there is active engagement in collecting such input with the goal of contributing to an eventual consensus practice guide.

Sex Offense, Assessment, Treatment

Psychiatry & Behavioral Science Section - 2015

122 Transgender Inmates: Considerations in Placement, Management, and Treatment in Correctional Facilities

Jennilee Tuazon, MD*, USC Institute of Psychiatry, Law, & Beh Science, PO Box 86125, Los Angeles, CA 90086-0125

After attending this presentation, attendees will understand the unique legal, medical, and psychiatric considerations inherent in the care of transgender inmates in the correctional setting. Attendees will also become familiar with the evolution of United States case law with respect to this population and how changes in the legal framework have impacted correctional regulations and treatment requirements regarding transgender inmates' placement, management, and treatment.

This presentation will impact the forensic science community by highlighting key legal, medical, and psychiatric considerations involved in the care of transgender inmates with the goal of identifying the necessary elements to providing comprehensive care that balances the individual's needs and safety against those of the correctional institution and of other inmates.

Transgender inmates pose unique challenges to correctional systems with respect to legal, medical, and psychiatric considerations involved in their care. A transgendered person is an individual whose "inward gender identity and outward gender expression differ from the physical characteristics of the body at birth." Thus, a male-to-female transgender person is one who is born with a male body but identifies with a female gender identity, and a female-to-male transgender person is one who is born with a female body but identifies with a male gender identity. For the vast majority of people, sex and gender are congruent. Transgendered individuals may suffer from *gender dysphoria* which the *Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM-5)* defines as a significant level of distress that may accompany the incongruence between one's experienced or expressed gender and one's assigned gender. Several studies have found high rates of psychiatric comorbidity in the transgender population as well as a nine-fold higher risk of suicide than that of the general United States population.

Transgendered individuals constitute a minority in the community. International studies estimate a prevalence ranging from approximately 1:10,000 to 1:45,000 male-to-female and 1:30,000 to 1:200,000 female-to-male transgender individuals; however, they are disproportionately represented in the incarcerated population. A 2003 study of the transgender community in San Francisco, CA, for example, found that nearly 14% of transgender individuals had been incarcerated at least once, a rate double the national incarceration average. Moreover, transgender inmates are at increased risk of victimization — in particular, sexual assault — within the correctional setting. A 2007 California prison study found that the prevalence of sexual assault in transgender inmates was more than ten times that reported by a random sample of inmates. This, in combination with evolving case law, has forced correctional systems to create institutional changes to meet the needs of this growing population.

Recent liberal case law has expanded transgendered inmates' rights to healthcare access and safe housing. For example, courts have renounced the use of the "freeze-frame" approach to hormone therapy which essentially freezes the dose of an inmate's hormone therapy treatment during incarceration and prohibits the initiation of hormone therapy. Despite case law, several states continue to utilize this method. Additionally, few correctional facilities in the United States have enacted policy changes to better address issues of placement, management, and treatment of transgendered inmates. Unlike more progressive correctional institutions in Australia, which take into account several risk factors to ensure safe and appropriate housing for their transgendered inmates, the vast majority of United States correctional facilities continue to assign housing solely based on an inmate's external genitalia, not gender identity. There are notable exceptions in California that are managed on the county, state, and federal levels, respectively: the K6G Unit at Men's Central Jail in Los Angeles, the California Medical Facility in Vacaville, and the Metropolitan Detention Center in Los Angeles. Regarding management, there are no uniform guidelines as to how to address a transgendered inmate. Most facilities allow bodily searches of an inmate to be performed by an officer of the same sex and prohibit gender-specific clothing and makeup. Finally, medical and psychiatric treatment focus on addressing access to hormone therapy and/or gender reassignment surgery as well as a transgender inmate's increased risk for psychiatric comorbidities and Human Immunodeficiency Virus (HIV) infection.

This presentation will review the literature on the housing, management, and placement of transgender inmates with respect to key legal, medical, and psychiatric considerations that inform their treatment. Finally, this presentation will present the necessary elements that constitute comprehensive care of these individuals.

Transgender, Corrections, Forensic Psychiatry

Psychiatry & Behavioral Science Section - 2015

I23 Zoophilia and the Law in the United States: Legal Responses to a Rare Paraphilia

*Brian J. Holoyda, MD**, University of California, Davis Medical School, Dept of Psychiatry & Behavioral Science, 2230 Stockton Boulevard, Sacramento, CA 95817; and *William Newman, MD*, University of California, Davis Medical School, 2230 Stockton Boulevard, Sacramento, CA 95817

After attending this presentation, attendees will understand the history and phenomenology of zoophilia, recent research findings on individuals who engage in human-animal sexual behaviors, pertinent case and statutory law about human-animal sexual contact in the United States, and the forensic implications of this body of law.

This presentation will impact the forensic science community by teaching useful epidemiological and phenomenological information about this rare paraphilia, and courts' and legislative bodies' historical response to human-animal sexual contact. It will also point out significant gaps in the current understanding of zoophilia as a risk factor for sexual violence recidivism. Attendees' competence at assessing individuals who have engaged in human-animal sexual contact will improve.

Sexual contact between humans and animals has occurred since the earliest recorded history and continues to this day. Alfred Kinsey's original research suggested that human-animal sexual contact was a relatively common phenomenon, but it is unclear to what degree his data are generalizable to the current population. More recent research has focused on self-identified "zoophiles" and their reported reasons for engaging in sexual intercourse with animals. Commonly identified reasons include being sexually attracted to animals and desiring to express love and affection for animals. In the Diagnostic and Statistical Manual, Fifth Edition, zoophilia is classified under the diagnosis of Other Specified Paraphilic Disorder and the diagnostic criteria require that an individual's paraphilia must cause distress or impairment, or result in harm or risk of harm to self or others.

Though societies' responses to bestiality have varied internationally, the response in the United States has typically involved condemnation and prosecution. Currently, there are 31 states with statutes prohibiting human-animal sexual contact. These statutes vary widely in terms of charge severity, potential punishments, and terminology used to describe zoophilic behavior. Despite the prevalence of anti-bestiality legislation, there is limited case law in the United States. Most commonly, bestiality arises in legal cases involving Sexually Violent Predator (SVP) civil commitments. In none of the identified cases has an individual diagnosed with zoophilia had his SVP status removed. Identifying offenders who commit acts of bestiality is important since these individuals may be at an increased risk of committing a variety of other sexual and non-sexual violent acts against humans; however, due to different laws between states, commonly used forensic risk assessment tools for sexual recidivism can yield different scores for individuals charged with or convicted of bestiality offenses. Forensic evaluators should consider this factor when conducting risk assessments. State legislatures should also consider modernizing their bestiality statutes to accord with current terminology and objectives for such laws.

Zoophilia, Sexual Offending, Recidivism

I24 A Pilot Study Comparing Hands-On and Hands-Off Child Pornography Consumers

*Sebastien Prat, MD**, Forensic Psychiatry Department, St Joseph's Centre for Mountain Health Services, 100 W 5th Street, Hamilton, ON L8N 3K7, CANADA; *Heather Marie Moulden, PhD*, Forensic Psychiatry Program, St Joseph's Healthcare-McMaster University, W 5th Campus, Hamilton, ON L8N 3K7, CANADA; *Carol Jonas, PhD*, Service de Psychiatrie, CHRU de Tours, Tours 37044 Cedex 9, FRANCE; and *Gary Andrew Chaimowitz, MD*, Forensic Psychiatry Program, St Joseph's Healthcare-McMaster University, W 5th Campus, Hamilton, ON L8N 3K7, CANADA

After attending this presentation, attendees will understand the difference between hands-on and hands-off child pornography consumers. Attendees will recognize the key characteristics to highlight in order to prevent an escalation and will also be aware of the criminal history of hands-on child pornography consumers.

This presentation will impact the forensic science community by assisting forensic psychiatrists and forensic psychologists to assess the risk these types of offenders pose to public safety.

Introduction: Child pornography is mostly considered as a hands-off offense. For more than a decade, it has been extensively described in an effort to try to understand the reasoning for downloading pornographic images or videos involving minors. For those who engage in these offenses, the motivation is not only driven by their deviant fantasies, the images are sometimes used to enhance contact with a minor. Interestingly, it was found that there are pedophiles who seek child pornography online and subsequently make contact with minors, but there are also child pornography consumers with clear pedophilic fantasies, but without any interest in acting out their urges. In that case, the main questions to ask are if they can decide at some point to assault a child and what could be the reason for the behavioral change. Therefore, it is interesting to compare both populations to know if differences can be highlighted in terms of childhood history, environment, and psychopathology.

Methods: A study was conducted based on a cohort of child pornography consumers with pedophilia diagnoses ($n=34$). The cohort was divided into two groups: those who committed sexual offenses toward children ($n=14$) and those who had never been convicted of anything other than downloading child pornography ($n=20$). Emotional and relational aspects, interpretation of the index offense, and quality of the interview were compared.

Results: No statistically significant difference between both groups in terms of their relationship or sexuality were found; however, statistical differences regarding their attitude toward the offense ($p=0.023$) and the sense of unreality they experienced during the consumption of the images online ($p=0.019$) were found. With respect to the assessment interviews, statistical differences, notably in cooperation ($p=0.001$) and capacity of introspection ($p=0.019$), were found.

Discussion: This study highlights significant differences between the hands-on and the hands-off pedophile. The hands-on offenders are less integrated and seem to have more cognitive distortion than the other group. The hands-off offenders have more insight toward the victims and the consequences of the offense. If they realize their behavior is inappropriate, it would be interesting to know why they do not seek help and cannot restrain their urges to download child pornography images. This study questions the existence of a subgroup of child pornography consumers, the risk they pose to the safety of the public, and how this risk can accurately be assessed. Further studies need to be conducted to understand the triggers that lead to offenses escalating from hands-off to hands-on.

Child Pornography, Risk, Hands-On Sexual Offense

125 **Pedophilia: A Crime or a Disease? How Should the Courts Address This Problem? A Case Study**

Thomas V. Brady, DMD, 1823 Boston Post Road, PO Box 622, Westbrook, CT 06498*

After attending this presentation, attendees will have a better understanding of paraphilias, specifically pedophilia, and will also be educated on what is integral for a proper investigation of a child abuse crime.

This presentation will impact the forensic science community by presenting information by which to view pedophilia in a different light. Hopefully, proper investigation, observation, and evidence collection will be used and the accused will be evaluated via new criteria.

Pedophilia or “The Sandusky Dilemma” — This discussion in no way condones or justifies Mr. Sandusky’s actions. A very intelligent individual made the observation that an inordinate percentage of senior male (mostly) adults that were being incarcerated were accused pedophiles. These were men with no prior criminal history, who started committing this heinous crime. Why? Studies vary, but a common statistic is 42%-50% of first-time senior offenders were classified as pedophiles.

Previously, pedophilia was considered a condition that a person accepts as their sexual preference. More recently, pedophilia has been increasingly viewed as a brain disorder. Pedophilia is defined as a sexual attraction to prepubescent children generally below 13 years of age. A child molester is not necessarily a pedophile. In general, the diagnosis of a pedophilia includes intense sexual fantasies and/or involvement with a prepubescent child for six months or more, must be at least 16 years old, and five years older than the victim(s). Hebephilia, ephebophilia, and teleiophilia are the other age-related sexual preferences.

Neuroscience is the multidisciplinary study of the brain, spinal cord, and associated neurons. Neuroscientists have performed **functional Magnetic Resonance Imaging (fMRI)** sexual preference studies on the brain stem, hypothalamus, hippocampus, and the prefrontal cortex. The fMRI is a magnetic resonance imaging instrument that measures blood oxygen levels at specific sites in the body. The measurement of the blood flow and volume is known as Blood-Oxygen-Level-Dependent (BOLD) imaging.

Studies on convicts showed that when suspected senior pedophiles were shown normative sexually arousing pictures, there was a lack of activation to the hypothalamus due to low levels of blood oxygen; however, when shown similar pictures of children, the blood levels increased. “Healthy” adult males in the study had the reverse findings. In other words, deficits in the activation of the prefrontal cortex were associated with pedophilic behavior. Pedophiles had reduced reactions in the pleasure centers of the brain indicating an altered sexual interest.

Proposed possible contributors to pedophilia include: genetic predisposition, head injury, brain oxygenation issues, tumors, arteriosclerosis, and other illnesses. So, is pedophilia a crime or a disease or both? How can a disease be a crime?

In a 2008 case of child abuse, a three-and-a-half-year-old boy was taken to the hospital with injuries to his penis. The mother’s story changed. At first, she claimed that the cat scratched the child then later claimed that the injury to the penis was due a fall from the toilet in the bathroom. The doctor sutured the penis and was ready to let the child leave when a nurse pointed out other injuries on the boy’s body. The police were called and during their investigation the hospital personnel and the police took multiple pictures of the injuries on the child; however, no ruler was used to take measurements nor swabs taken to look for DNA or amylase found in saliva.

The police continued their investigation at the child’s home. When the bathroom was searched, blood splatter was found on the wall opposite the toilet and photographed, using rulers. The wall was three feet from the toilet. The boy was less than 39 inches tall. Bloody tissue was noted in the wastebasket, but not taken into evidence.

Among the injuries were two apparent bitemarks on the boy’s right leg. The mother said the boy’s five-year-old brother was the biter. With image enhancement software, the apparent bitemarks were examined and measured. The hospital had failed to notice an apparent bitemark at the base of the penis. The lesion was also examined using image enhancement software. Models were taken from the mother and boyfriend. The brother had been sent to Puerto Rico but bitemark models were obtained and included in the examination. An overlay of the models eliminated the brother and the mother, but seemed to coincide with the boyfriend.

When confronted with the evidence, the boyfriend admitted to abusing the child. He was sentenced to ten years in jail, which was suspended after three years for risk of injury to a minor. He was not charged with sexual assault because no rulers were present in the pictures. He is already out of jail and does not have to register as sex offender.

I26 **Contemporaneous Assessments of Testamentary Capacity and Undue Influence: Strike While the Iron Is Hot**

Daniel A. Martell, PhD, Park Dietz & Associates, 2906 Lafayette, Newport Beach, CA 92663*

After attending this presentation, attendees will gain a better understanding of the advantages offered by contemporaneous evaluations of testamentary capacity and undue influence at the time a will or estate document is executed.

This presentation will impact the forensic science community by offering a new standard of care for conducting testamentary capacity and undue influence examinations that can reduce the risk of future litigation and related unwanted outcomes.

Contested wills, trusts, and estate plans are extremely expensive to litigate and can significantly erode the corpus of the estate while simultaneously undermining the wishes of the testator and creating turmoil among surviving family members and remaindermen. This is particularly true when late changes are made to an existing will or estate plan. Planning for the possibility of a future will contest is both a prudent and cost-effective strategy that holds the potential to avoid these typical adverse outcomes.

A careful and well-documented assessment of the testator's capacity prepared at the time that a will is executed or any significant changes are made can document and preserve evidence of the testator's competency and freedom from undue influence. This simple step can prevent years of litigation and unnecessary delays in executing the client's desires.

International standards and practices in this area of mental health law will be presented with a focus on the laws in Great Britain, where contemporaneous examinations of testamentary capacity are the norm, and the practice is referred to as "The Golden Rule" following the landmark case of *In Re: Simpson Deceased* (1977). The legal criteria for such assessments will be presented, flowing from *Banks v. Goodfellow* (1870), with a focus on the application of contemporary forensic behavioral science methods to these well-established legal standards.

A proposed standard of care for such evaluations will be presented which includes both psychiatric examination and neurocognitive testing. Evaluations are generally conducted as close in time as possible to the date that a will or trust will be signed and can usually be completed in one day. The process includes: (1) a careful review of the medicolegal record; (2) objective psychodiagnostic and neuropsychological testing; (3) a meticulous forensic psychiatric examination of the testator(s); and, (4) interviews of significant others as needed.

A customized neuropsychological test battery is administered, tailored specifically to those cognitive functions most relevant to testamentary capacity, including attention, concentration, memory, and executive functioning. Psychodiagnostic testing is used to evaluate psychiatric symptoms. The forensic psychiatric examination includes taking a complete history, mental status examination, careful documentation of the testator's competency, and assessment of the factors that increase susceptibility to, or protect against, undue influence. The evaluation can be digitally recorded if desired. A comprehensive report is then prepared to be filed with the estate plan.

In an effort to illuminate the advantages of the proposed model of contemporaneous examinations, case examples will be used to illustrate the complexities and complications of waiting until after the death of the testator to evaluate capacity. Problems and pitfalls likely to be encountered by adopting this approach will be discussed and their potential remedies and advantages will be explored. By changing the thinking about how and when to evaluate testamentary capacity and the possibility of undue influence, there is great potential to safeguard both the estate's financial resources and the family's peace of mind.

Testamentary Capacity, Undue Influence, Neuropsychological Testing

Psychiatry & Behavioral Science Section - 2015

127 Extreme Emotional Disturbance Defense: From the Heat of Passion to a Reasonable Explanation

Megan M. Mroczkowski, MD*, 3959 Broadway, New York, NY 10032; Christopher Racine, MD, MPH*, 462 First Avenue, Office 214B, C Bldg, New York, NY; Danielle Kushner, MD*, NYU School of Medicine, 550 First Avenue, New York, NY 10016; Karen B. Rosenbaum, MD*, 49 W 24th Street, Ste 908, New York, NY 10010; and Eric Goldsmith, MD*, NYU School of Medicine, 550 First Avenue, New York, NY 10016

After attending this presentation, attendees will: (1) understand the history of the Extreme Emotional Disturbance (EED) defense in the mitigation of prosecutions for murder; (2) compare different states' statutes; (3) examine jury instructions for this defense; and, (4) engage in a discussion of the New York State case, *People v. Sepe*, as a case example of the EED defense. Mr. Sepe was charged with murdering his wife and used the defense that the stress regarding the preparation of a family Easter dinner led him to commit the murder.

This presentation will impact the forensic science community by increasing the understanding of the EED defense and improving competence in psychiatric assessment of defendants.

In 1967, the New York Penal Law dealing with mitigation of prosecutions of murder was revised. The criterion that the offense occurred in the "heat of passion" was replaced with "extreme emotional disturbance for which there is reasonable explanation or excuse."¹ As an affirmative defense, the defendant must prove he or she was provoked by the victim's actions and that a reasonable person would also be provoked.¹ This presentation will discuss both the history of this defense and the current New York State law. This law will be compared with the laws in other states.

A discussion of the jury instructions provided for this defense will be explored. These include: (1) the defendant must have had an extreme emotional disturbance; (2) in committing the homicide, the defendant must have acted under the influence of that extreme emotional disturbance; and, (3) there must have been an explanation or excuse for such extreme emotional disturbance that was reasonable.

There have been many studies describing the use of the "Not Criminally Responsible" or "Insanity Defense"; however, there are very few studies describing other psychiatric defenses. One such study looked at the New York County criminal justice system. The results of the study showed that similar to the insanity defense, EED defense is rarely used by defendants in the criminal justice system. The plea rate for this particular defense by criminal defendants was 0.84%.³ Furthermore, the defense won the case in only one instance when in a jury trial.² In this sample, the EED defense success rate was 39% of the times that it was entered; however, it was noted this was usually when the prosecutor accepted the particular argument offered by the defense.³

The discussion will conclude with a review of the New York State case *People v. Sepe*, a prominent case utilizing the EED defense from 2009.³ The judicial reasoning behind the verdict, which exemplifies the challenges of using this defense, will be highlighted.

Psychiatry & Behavioral Science Section - 2015

I28 The Power of Intuition in Deception Detection

Christopher Fischer, MD, UCLA Medical School, 760 Westwood Plaza, C8-193, Los Angeles, CA 90024*

After attending this presentation, attendees will be competent in identifying the strengths and limitations of using intuition for detecting deception and learn how intuition can be applied to different fields in forensic science. Drawing from recent research in several different disciplines, this presentation proposes that the ability to detect lies can be improved by harnessing the power of intuition.

This presentation will impact the forensic science community by integrating knowledge and research from several different disciplines to provide a clear and coherent picture of the latest understanding of the use of intuition for detecting deception.

Humans tell lies all the time. The lies told range from minor, inconsequential white lies to major, high-stakes lies. Humans are also extremely poor lie detectors and fare no better than chance at telling whether or not someone is lying or telling the truth. Although humans are poor at ascertaining when someone is lying or telling the truth, there is some evidence that a small number of individuals are particularly skilled at detecting deception. Some researchers have postulated that these individuals are able to deliberately look for and find ultra-fast, subtle changes in facial expressions (microexpressions) and other behaviors that serve as cues that someone is not being genuine; however, other researchers argue that there is no difference in individuals' abilities to detect deception and question whether people are really able to detect different cues.

This presentation proposes that accurate deception-detection ability does not rely on any conscious and deliberate discovery of cues that someone is lying, but instead relies on intuitive or unconscious processes. Dual-Process Theory postulates that humans operate using two types of thinking or "systems" when making decisions — one intuitive and the other deliberate. Intuitive thinking is considered a fast, automatic, unconscious process, whereas deliberate thinking is considered a slow, conscious, analytic process. This presentation explores the potential application of intuition to detecting deception. Recent research demonstrates that by forcing people to use their intuition, accuracy of deception judgments increases substantially. Implications of these findings and future potential for intuition in different fields will be discussed.

In the spirit of the 2015 American Academy of Forensic Sciences (AAFS) Annual Scientific Meeting, *Celebrating the Forensic Science Family*, and the three major planks of the meeting, this presentation is a collaboration between a mentee and mentor, involves learning from a variety of disciplines including psychiatry, psychology, law-enforcement, and evolutionary biology, and is designed to stimulate discussion and future research into the field of deception detection.

Intuition, Deception, Detection

Psychiatry & Behavioral Science Section - 2015

I29 Incapacity of the Mind Secondary to Medication Misuse as a Not Criminally Responsible (NCR) Defense

*Sebastien Prat, MD**, Forensic Psychiatry Department, St Joseph's Centre for Mountain Health Services, 100 W 5th Street, Hamilton, ON L8N 3K7, CANADA; *Bruno Losier, PhD*, Forensic Psychiatry Program, St Joseph's Healthcare-McMaster University, W 5th Campus, Hamilton, ON L8N 3K7, CANADA; *Heather M. Moulden, PhD*, Forensic Psychiatry Program, St Joseph's Healthcare-McMaster University, W 5th Campus, Hamilton, ON L8N 3K7, CANADA; and *Gary A. Chaimowitz, MD*, Forensic Psychiatry Program, St Joseph's Healthcare-McMaster University, W 5th Campus, Hamilton, ON L8N 3K7, CANADA

After attending this presentation, attendees will be aware of the types of Not Criminally Responsible (NCR) defenses according to the Criminal Code of Canada. Attendees will learn about the concept of non-insane automatism and will be informed about an atypical case of non-insane automatism.

This presentation will impact the forensic science community by providing specific knowledge about the possibility of raising an NCR defense in a case of Parkinson's disease, which has not been previously described.

Introduction: Non-insane automatism can be an important factor for consideration in an NCR assessment. The literature provides numerous examples of this including hypoglycemia, postictal state, or sleep walking. To be able to raise this possibility and make a sound case, there needs to be a clear-cut relationship between the medical condition and the behavior during the offense.

Case Report: This study describes the case of a 77-year-old man, with no previous criminal history, suffering from Parkinson's disease, who was charged with an unprovoked attack upon his wife. During the NCR assessment, his presentation was unremarkable for any aggressive behavior or psychotic symptoms. During the evaluation, it became evident that the patient had increased the dosage of his medication to better control the motor symptoms associated with his Parkinson's disease. The impact of this was captured on two videos: the first on his admission to a general medical unit and the second two days following medication adjustments, with remarkable differences in his Parkinson symptoms and behavior. The first video showed a patient with better control of his movements and an ability to walk easily, but who seemed disinhibited. In the second video, when he took the regular dose of his medication, he had more tremor and a poor facial expression. While reviewing the events preceding, during, and following the index offense, the conclusion was that the unfortunate and non-deliberate misuse of the medication distorted his reality and judgment sufficiently to alter his ability to appreciate the nature and quality of his actions.

Discussion: The misuse of a medication can hardly lead to an NCR defense, unless proven that the medication provoked a confusion state or non-restrainable behavioral symptoms and that the offender was unaware of the negative consequences of misusing. This argument is often used, in relation with benzodiazepine or antidepressant. The analysis of the behavioral pattern of the offender can allow a better understanding of the role of the medication before or during the incident. As far as is known, misuse of a medication used to treat Parkinson's disease has never been previously described as an NCR defense. With this explanation, in consultation with the victim, the individual was acquitted.

Non-Insane Automatism, Not Criminally Responsible, Parkinson's Disease

Psychiatry & Behavioral Science Section - 2015

I30 Unintentional Child Neglect: Literature Review and Observational Study

*Emily Friedman, BS**, 857 Leonard Road, Los Angeles, CA 90049; and *Stephen B. Billick, MD**, 901 Fifth Avenue, New York, NY 10021-4157

The goals of this presentation are to help attendees better understand the issue of unintentional child neglect, evaluate risk factors leading to neglect, and evaluate the consequences of child neglect.

This presentation will impact the forensic science community by instilling a need for further research into the issue of child neglect, specifically unintentional neglect. With a more consistent and cohesive definition of neglect and a better understanding of its associations and risk factors, it will be possible to better address the problem.

Child abuse is a problem that affects over six million children in the United States each year. Child neglect accounts for 78% of those cases. Despite this, the issue of child neglect is still not well understood, partially because child neglect does not have a consistent, universally accepted definition. Some researchers consider child neglect and child abuse to be one and the same, while other researchers consider them to be conceptually different. Factors that make child neglect difficult to define include: (1) cultural differences; motives must be taken into account because parents may believe they are acting in the child's best interests based on cultural beliefs; (2) the fact that the effect of child abuse is not always immediately visible; the effects of emotional neglect specifically may not be apparent until later in the child's development; and, (3) the large spectrum of actions that fall under the category of child abuse.

Some of the risk factors for increased child neglect and maltreatment have been identified. These risk factors include socioeconomic status, education level, family composition, and the presence of dysfunctional family characteristics. Studies have found that children from poorer families and children of less-educated parents are more likely to sustain fatal unintentional injuries than children of wealthier, better-educated parents. Studies have also found that children living with adults unrelated to them are at increased risk for unintentional injuries and maltreatment. Dysfunctional family characteristics may be even more indicative of child neglect. Parental alcohol or drug abuse, parental personal history of neglect, and parental stress greatly increase the odds of neglect. Parental depression doubles the odds of child neglect; however, more research needs to be done to better understand these risk factors and to identify others. Having a clearer understanding of the risk factors could lead to prevention and treatment as it would allow for health care personnel to screen for high-risk children and intervene before it is too late. Screening could also be done in the schools and organized after-school activities. Parenting classes have been shown to be an effective intervention strategy by decreasing parental stress and the potential for abuse; but there has been limited research on this approach. Parenting classes can be part of the corrective actions for parents found to be neglectful or abusive, but parenting classes may also be useful as a preventative measure, being taught in schools or readily available in higher-risk communities. More research is needed to better define child abuse and neglect so that it can be effectively addressed and treated.

Child Neglect, Unintentional Injuries, Maltreatment

Psychiatry & Behavioral Science Section - 2015

I31 Assessing and Addressing Preteen Violence

John L. Young, MD, 203 Maple Street, New Haven, CT 06511-4048*

After attending this presentation, attendees will understand the unique, relevant features characterizing the very youngest perpetrators of violence, including possible causes and means for prevention.

This presentation will impact the forensic science community by facilitating the direction of critical professional attention to the social impact of violence by pre-adolescent youths.

Traditionally, seven years of age is regarded as the “age of reason,” the time by which a substantial level of moral discernment can be expected. There is a long legal history that at least loosely follows this notion. Yet it is known from many investigators, including James, Kohlberg, and Piaget, that for many purposes, it is an oversimplification. Moreover, current work by Paul Bloom has been uncovering the ability to express morally based preferences in infants during their first year.

While still quite young, children may in extreme cases give violent expression to their choices. Examples include a first-grader in Michigan shooting a classmate, two English schoolboys killing toddler James Bulger, and an 11-year-old Chicago boy accused in the slaying of a 14-year-old girl. These perpetrators are all preteens and appear to form a class distinct from the likes of adolescent school shooters, bullies, hazers, or so-called gang bangers. Unlike their older counterparts whose violence surprised most of those who knew them, these younger children are more likely to show serious disturbances as early as their fourth year. Fortunately, they are apparently rare, but hard to count accurately or to even discuss.

Suggested causes for pre-teen violence range widely. Brain imaging and genetic techniques so far have not yielded any distinguishing findings. Early attachment disturbances are suspect. A wide range of substances misuse may be a factor, including herbal remedies that appeal to the very young. The easy availability of guns may play at least a secondary role. Significant controversy continues regarding the causal role of media violence, whether through the internet, films, television, radio, video games, printed periodicals, or even books.

Potential remedies are many and many can be applied simultaneously. Preventive measures focus on decreasing violence in the environment with alternative positive opportunities to socialize. Parental training efforts have proven welcome and helpful. Introducing enforcement of existing but ignored laws at all levels can be effective. Close attention to day-care operations is probably warranted, in view of a study showing that length of exposure to day care may correlate at least slightly with disruptive behavior in the early years of school. School-based programs can systematically encourage appropriate responses to routine experiences that would otherwise elicit violence. When prevention fails, there is a minority advocating school-based corporal punishment.

Finally, pre-teen violence does not respect international boundaries. Thus, it is important to make the effort needed to compare relevant concerns and experiences across diverse cultural and political contexts. History judges societies according to their treatment of their most vulnerable members.

Violent Children, Violence Prevention, Assessment

Psychiatry & Behavioral Science Section - 2015

I32 Perception of Police Among Adolescents in Istanbul

Mine Öztaşçılar*, Bahçeşehir University, Ciragan cad No: 4 Besiktas, Istanbul 34353, TURKEY; and Neylan Ziyalar, Cerrahpasa Yerleskesi, Adli Tip Enstitüsü, Istanbul, TURKEY

The goal of this presentation is to help attendees identify Turkish adolescents' perception of the police. Attendees will critically examine the factors shaping adolescents' perception of police in Istanbul.

This presentation will impact the forensic science community by highlighting the importance of police-citizen relationships in order to improve police response to crime.

With the rise of community policing around the globe, many studies have started to focus on the police-community relations to improve police departments' response to community needs. Thus, citizens' perception of the police has become a primary focus for scholars. It is believed that citizens who are satisfied with the police are more likely to cooperate with the police, which may increase the police effectiveness in crime control. Considerable research has shown that personal experiences with the police, demographic characteristics including gender, age, socio-economic status, etc., and neighborhood characteristics are correlated with the perception of police, indicating that those living in poor neighborhoods, those who are young, and having negative contact with the police resulted in low levels of satisfaction with the police. Because many of the studies were conducted outside of Turkey, there is a lack of empirical evidence that measures adolescents' perception of police in Istanbul. The main goal of this study is to empirically assess Turkish adolescents' police perceptions in Istanbul.

The goal of this study was to examine high school students' perceptions of police in Istanbul, Turkey. Data were analyzed based on 1,785 surveys conducted with Turkish adolescents attending middle and high school in Istanbul between October and December 2013. The survey instrument used to collect the data for this study was a two-page questionnaire that consisted of 49 questions and statements. Twenty items were related to perception of police, including the following statements: "the police are dishonest" and, "the police are biased." The remaining questions asked about the students' demographic characteristics, socio-economic status, and perceptions of safety in their community.

In the sample, 56.7% of the respondents were female. The average age of the adolescents was approximately 12.5 years old. Almost all lived with their parents. Approximately 13% had previous contact with police. Of these, 53% perceived their neighborhood as safe in terms of crime. The average value on the 20 items relating to the police was 4.2, indicating that adolescents reported slightly positive perceptions of police. Female students' ratings of the police were significantly higher than males, which was consistent with the studies.

In general, the results showed that students who had previous contact with police rated police more favorably than those who had no contact with the police in the past. Overall, adolescents reported positive perception of police regardless of gender, neighborhood characteristics, and background. Consistent with the previous studies, adolescents living in low-income areas perceived crime as a problem in their neighborhoods and recognized the importance of the police as a solution to crime. This research is the first to examine Turkish adolescents' perception of police in Istanbul. These findings can help the police to improve their services and to promote better police-citizen relationships.

Perception of Police, Adolescents, Turkey

Psychiatry & Behavioral Science Section - 2015

I33 Behavioral Characteristics and Personality Traits of the White-Collar Organized Criminal and the White-Collar Organized Community

Janet M. Schwartz, PhD, PO Box 36058, Canton, OH 44735-6058*

After attending this presentation, attendees will be able to: (1) describe a milieu of perspectives on white-collar criminals including that of Main Street media, history, and criminal justice; (2) list five categories of 21st-century white-collar crime; (3) identify behavioral characteristics and personality traits of the white-collar organized criminal and the white-collar organized community; (4) demonstrate how to assess the presence of psychopathy and the risk of dangerousness in individuals when preparing for litigation or throughout an investigation; (5) understand the significance of the psychopathic continuum; (6) learn tactics such offenders use to avoid retribution; and, (7) list ways to protect oneself, one's family, and one's community from falling prey to these social predators.

This presentation will impact the forensic science community by educating attendees with a comprehensive overview of white-collar crime and ways to detect patterns of corruption. Developing an awareness of the behavioral characteristics and personality traits of white-collar organized criminals and the white-collar organized community is a preventative measure against future victimization.

Forensic Fraud Research, Inc. is a non-profit, not-for-fee investigative firm that performs intelligence-gathering efforts and works collaboratively to help strengthen our government. Through work at Forensic Fraud Research, Inc., a gateway of opportunities to perform investigations and to gather semi-structured interviews with 300+ victims, whistleblowers, alleged offenders, offenders, alleged offenders' spouses and family members, witnesses, and bystanders was possible. The results of this study have yielded the "Behavioral Characteristics and Personality Traits of the White-Collar Organized Criminal and the White-Collar Organized Community" (Note: When the study had conducted 100 interviews, the United States Department of Justice requested permission to videotape the presentation for educational purposes and for use on their Justice Television Network (2005)). Of particular interest is the role of the manipulative cycle in the decision to deceive and to carry out the deceptive act.

Learning when to intervene is essential in order to prevent the contemptuous delight of the white-collar organized criminal. Rich anecdotal data gleaned from working on the frontline substantiates the findings. As security incidents are frequently an aspect of this work, determining the presence of psychopathy and assessing the risk of danger is critical. The criteria utilized will be shared. While there is no universal definition of white-collar crime, the accepted definition used by the United States Department of Justice and the "consensus definition" offered by the National White-Collar Crime Center (NW3C) will be discussed. The definition of organized crime as provided by Investigator John Clark, High Intensity Drug Trafficking Areas (HIDTA) -Money Laundering Unit of the Federal Bureau of Investigation (FBI), clarifies the link of collusion in corruption. According to the Association of Certified Fraud Examiners' 2014 Report to the Nations, "When collusion is involved, median losses due to fraud increase substantially." Attendees will be empowered with helpful information that may prove to be useful in both their professional and personal lives.

I34 Honor-Based Violence: A Cultural Problem!

*Mete K. Gulmen, PhD, MD**, Cukurova University, School of Medicine, Dept of Forensic Medicine, Adana, 01330, TURKEY; and *Sunay Firat, PhD*, Cukurova University, Adana Health Sciences Dept of Nursing, Balcali, Adana 01330, TURKEY

After attending this presentation, attendees will gain an understanding of the relationship that exists between the individual environmental factors of honor-based killings committed by family members and the reasons behind such acts in various cultural contexts, thus assisting in the development of preventive interventions.

This presentation will assist the forensic science community by identifying the causes of culturally and traditionally accepted crimes committed against female members of the family by their male relatives and will assist in the development of preventive programs by preparing the grounds for the establishment of policies and strategies that will eventually pave the way for preventive and ameliorative measures.

Honor can be defined as the commitment to moral principles and social values such as chastity.¹ In particular, its meaning in Turkish refers to the rules regarding sex in the Islamic religion. In Turkey, honor is considered generally to be synonymous with sexual purity.^{2,3}

Despite the different perceptions among different people, it has been observed that the most common trend is to consider women, their bodies and their sexuality, and their control as elements of honor. In this context, to the male members of the family, honor relates to a man's wife, sister, mother, other family members, and even to the other women in his circles. As such, he has a duty to keep an eye on all of these women. This increases the pressure on women, especially in areas where tribal and kinship bonds are strong or where small-scale and face-to-face relationships are established. By controlling her sexual behavior, a woman provides information to society not only about her own honor but also about the honor and pride of her family.⁴

Behavioral repertoires that can be considered as components of a woman's sexuality comprise not only her sexual relationships but also many other forms of behavior, such as her way of dressing, holding hands with the opposite sex, requesting a song for a man on television or radio, kissing, and flirting.⁵

Honor killings are committed as a social reflection of the cultures in which women are considered a commodity.^{6,7} If a woman in Turkey defames her own honor or the honor of her family through her behavior, she may be punished in various ways (verbally and/or physically), as in many other countries. In the case of honor killings, a single perception is enough to trigger a crisis.⁸

According to research conducted by the United Nations Population Fund, more than 5,000 women are killed every year in honor-based killings around the world.⁹

According to The Grand National Assembly of Turkey (TBMM), 1,091 honor-based killings took place between 2000 and 2005, and 322 of those were reported as murders committed in the name of honor. Unfortunately, as the statistical data related to crimes are classified according to the terms of crime, as stated in the Turkish Penal Code, honor killings are recorded only as homicides in the statistics, making it difficult to compile concise data related specifically to honor killings.¹⁰

This study collected only the ten files that were sent to The 2nd, 3rd, and 4th High Criminal Courts of the Adana Courthouse between June 2008 and June 2014 and that were registered in the Adana Courthouse, the National Justice Network Information System.

Providing a clear overview to attendees, focus will be on the individual cases, the cultural infrastructure of the geographical regions in which the killings took place, and the local social attitudes. The cases presented here have all been finalized with court decisions. Focusing only on socio-economic conditions and social pressure as the causes of honor killings may, in a way, cause the violence committed by a person or people to be overlooked. Prevention of honor killings should start by setting aside the current perspective toward the concept. In order to change the traditional perception and judgments of gender, there are a number of necessary steps that must be taken, primarily by public institutions and establishments, who must take effective measures to ensure that the security of life for women is a priority.

Violence against women has been the subject of research for the last 50 years, while forensic science has been taking an interest in the issue for the past 30 years; despite this, significant developments have only been realized within the last ten years. For this reason, it is vital that this matter be a subject of perpetual discussion in the field of forensic sciences so as to improve the level of awareness/consciousness not only in the field of forensic sciences, but also in social development. Accordingly, this study recommends that these cases should be considered on a much broader base and discussed more at an international level.

I35 Paternal Filicide for Spousal Revenge: The Male Side of Medea's Syndrome in the Italian Population Over the Last Ten Years

*Federica Collini**, Via Mangiagalli 37, Milan 20133, ITALY; *Angelo Giuseppe De' Micheli, MD*, Via Luigi Mangiagalli 37, Milan 20133, ITALY; and *Isabella Merzagora Betsos, PhD*, Via Luigi Mangiagalli 37, Milan 20133, ITALY

After attending this presentation, attendees will understand Medea's syndrome as it applies to fathers, by observing the prevalence of this syndrome in Italy during the last ten years (from 2005 to 2014).

This presentation will impact the forensic science community by demonstrating that a substantial proportion of cases due to Medea's complex are attributable not only to mothers but also to fathers. Although it is traditionally thought that mothers kill their children for revenge against their fathers, the opposite can also happen.

By consulting the archives of an important Italian national newspaper, "Corriere della Sera", this study chronicled all the cases of children or teenagers killed by their fathers due to spousal revenge. Twenty-eight cases were analyzed, focusing on spatial and temporal distribution, age, nationality of the fathers and children, gender of the children, the fathers' occupations, the methods of killing, and any association with suicide.

Results showed that 64.5% of cases occurred between 2005 and 2009, mostly in February, July, and December; in fact, these are holiday months (Valentine's Day, summertime, or Christmas, respectively), which may explain the high concentration of cases during this period. Regionally, 57.1% of cases occurred in Northern Italy, but major population density in other regions must be taken into account; 82.1% of perpetrators were Italian with others being from Egypt, Slovenia, Romania, and Nigeria, demonstrating that it is not a phenomenon linked to immigration. Additionally, 42.8% of these fathers were employed, 25% were unemployed, and 21.4% were self employed, with most experiencing financial difficulties, showing this may be a risk factor. Fifty-four percent of the children killed were between one and ten years of age. This differs from female perpetrators, who generally kill their children when they are less than one year of age. Moreover, 67.6% of the children killed were male, as if there were a sort of gender identification with the victim. The methods of killing were mostly violent: 39.3% by blunt force trauma; 21.4% by gunshot trauma; 21.4% by sharp force trauma; only 14.3% were due to asphyxia, which is a less violent method generally used by maternal killers. In 51.3% of the cases, a relationship separation existed, evidencing a possible strong correlation between these crimes and jealousy or revenge. In 24.3% of the cases, perpetrator depression was associated with the act and in only 8.1% of the cases, other contributors such as substance abuse or cultural or religious divergences were noted. In 64.3% of the cases, a perpetrator suicide or attempted suicide was involved, possibly indicating guilt or a great sense of inadequacy and unease rooted in the father who committed the act.

This study sheds light on an almost-forgotten segment of fathers who murder their own children simply for revenge against their partners, representing the male side of the so-called Medea's syndrome.

Medea Complex, Filicide, Revenge

Psychiatry & Behavioral Science Section - 2015

I36 Suicide Among Turkish Police Officers From 2003 to 2013

Neylan Ziyalar, Cerrahpasa Yerleskesi, Adli Tip Enstitüsü, Istanbul, TURKEY; Mine Özasçılar, Bahçesehir University, Ciragan cad No: 4 Besiktas, Istanbul 34353, TURKEY; Can Çalici, Istanbul University Institute of Forensic Sciences, Cerrahpasa, Istanbul, TURKEY; and Davut Acar, Turkish National Police Department, Istanbul, TURKEY*

The goal of this presentation is to help attendees understand police suicide trends in Turkey between the years 2003 and 2013. Attendees will critically examine the relationship between police suicides and demographic variables in Turkey.

This presentation will impact the forensic science community by describing police suicide trends in Turkey over a ten-year period, covering the years from 2003 to 2013.

Police work is one of the most stressful occupations; research found a significant correlation between stress and suicide among police officers. Thus, suicide among police officers has been extensively studied. It is alleged that police are at higher risk of suicide than the general population; however, studies have shown that police suicide rates are lower than those of the general population. It is widely argued that police suicides are vastly under-reported due to social stigma, insurance and religious reasons, and loyalty to the department. Regardless of police suicide statistics, the death of a police officer has a significant impact on the family of the victim and coworkers within the department.

Most of the studies on police suicide are focused on United States police forces and there are few articles based on other countries, including England and Canada; therefore, the goal of this study was to examine police suicides in Turkey between 2003 and 2013. This study also considered police suicides in the context of general population suicide rates to determine whether police suicide rates are higher or lower than the general population. A secondary purpose was to explore the relationship between police suicide rates and gender, age, marital status, reasons, method of suicide, and years-in-service. Data for this study was gathered from the Turkish National Police Department. The annual number of police suicides were stratified by gender, age, degree, marital status, reported reasons for suicide, years-in-service, and method of suicide during the study period, 2003-2013. The annual suicide rate was calculated as the number of suicides per year by dividing the number of officers on the force.

Over ten years, the total number of police suicides was 277. The overall suicide rate among police officers during the period was 17.6 per 100,000 person-years. Rates in married police officers were an average of 40% higher than other groups including divorced and single officers. Recognizing the many stresses associated with police work, it is not surprising that suicide among married police officers is higher. Almost all police suicides resulted from firearms due to the easy access and socialization of police officers to handguns. During the entire period from 2003 to 2013, there were fluctuations in the rates of police suicides; there were no trends. Compared to the demographically adjusted suicide rate for the Turkish population (3.98 per 100,000 person-years), the police officer suicide rate was higher than the general population.

The study findings showed that police suicide rates are much higher among male and married officers. The higher rates of suicide among married police officers can be interpreted by considering that police work affects the family of police officers in substantial ways, particularly shift work and temporary assignments which disrupt family life. It should be noted that the fluctuations in police suicide over this ten-year period in Turkey reflects cultural changes, especially changing attitudes toward the police.

Police Officers, Turkey, Suicide

Psychiatry & Behavioral Science Section - 2015

I37 Parricides and Crime Scene Behaviors — Do They Tell the Story?

Wade C. Myers, MD*, Brown University, Dept of Psych & Human Behavior, Forensic Psychiatry Program, 1 Hoppin Street, Ste 204, Providence, RI 02903; and Eleanor B. Vo, MD*, OmaDesala Psychiatric Services, 1901 N Olden Avenue Ext, Ste 3A, Ewing, NJ 08618-2111

After attending this presentation, attendees will be more knowledgeable about psychological motivations for parricide cases and how crime scene analysis can aid in understanding the crime and the possibilities of preventing it.

This presentation will impact the forensic science community by expanding knowledge regarding the victims and offenders of parricide cases by looking at the crime scene behaviors for insight into family dynamics and motives for the crime.

Parricides, while being a rare event, are one of the most sensational crimes that attract the attention of the media, clinicians, and researchers worldwide. Much research has been done on the topic of parricide despite the incidence being only about 1.5% to 2.4% of all homicides yearly. Often research focuses on the offender's and the victim's characteristics in order to evaluate the crime and motive; however, there is very limited research into the crime scene behaviors. Basic knowledge of parricide in multiple studies shows that offenders are typically adult White males with mental health issues who often target their mothers. Differences between adults and adolescents who commit parricide show that adults have a higher incidence of schizophrenia or a psychotic process being present at the time of the crime.^{1,2} Some studies have pointed to abuse as the motivation in adolescents who commit parricide. Dr. Kathleen Heide has shown in multiple studies the differences between adult and adolescent offenders, such as most single victim-single offender cases of parricide involve adult males of White, non-Hispanic ethnicity. Studies have shown that the age of the offender is significant as to which parent is targeted as the victim (i.e., offenders less than 30 years old target the father, stepfather, and stepmother, while offenders who are older target their mothers as the victim).³⁻⁵

While research has focused on demographics, motive, social, legal, and psychological factors such as mental health and abuse history, minimal research of crime scene behaviors in parricide cases have been explored. Other types of homicides are often profiled based on crime scene analysis, so why not open this door when looking at parricides as well? Previous analysis of crime scene research in parricides is limited to looking at the weapons the offender used and signs of overkill. Crime scene analysis and profiles have been invaluable tools for investigators and police to help understand the offender of violent crimes, but this concept has not been used to look at parricide cases in order to better understand the events and circumstances that lead to an individual taking their parent's life. To examine the components of crime scene behaviors and its implications within parricide, data from adolescent parricides will be presented. Due to the high incidence of psychosis in adult cases of parricide, this data was excluded from this study. This study will present preliminary data about adolescent parricide offenders and crime scene behaviors such as condition of body when found (covered, face covered, and moved or hidden); type of attack (blitz, surprise, or con/deceived); presence of defensive wounds; signs of overkill; weapon used; confession type/plans to avoid detection; and location of the attack. The hope is that by examining these unique crime scene behaviors, better insight into parricide can be acquired.

I38 Suicide by Suffocation: A Case Report of an Elderly Woman Who Completed Suicide by Suffocation

*Cynthia Rutherford, DO**, Bronx Lebanon Hospital, 1276 Fulton Avenue, Bronx, NY 10456; *Amina Ali, MD**, Bronx Lebanon Hospital Center, 1276 Fulton Avenue, Bronx, NY 10456; and *Panagiota Korenis-Rios, MD**, 1276 Fulton Avenue, Bronx, NY 10456

After attending this presentation, attendees will be informed about rare methods of committing suicide and, in particular, learn about suicide by suffocation/asphyxiation. Attendees will also be alerted to forensic issues related to patient suicide; additionally, risk factors for completing suicide will be reviewed. Recommendations regarding psychoeducation to health care providers and patients will be explored.

This presentation will impact the forensic science community by educating attendees about rare methods of suicide and populations vulnerable to suicide by suffocation.

Each year, approximately 38,364 people die by suicide, making it a leading cause of preventable death in the United States, surpassing automobile accidents (33,687). Studies also report a 16% increase in death by suicide during the period 2000-2010. This has resulted in 12.6 people dying per day by suicide in the United States. Having a mental illness or engaging in substance use puts one at a significantly higher risk for suicide completion. While firearms continue to be the most common method for suicide completion, studies suggest that suicide by hanging or asphyxiation showed the most dramatic increase. In 2000, 19% of all suicides were completed by hanging or asphyxiation and in 2010, it rose significantly to 26%. While suicide by hanging or asphyxiation is on the rise, specifically, suffocation using a plastic bag remains an extremely rare method of suicide and it is fairly underreported in the literature. Literature indicates that the majority of plastic bag suffocation is in the context of a suicide attempt carried out by either those with mental illness or the elderly using sedatives.

Case: A case of a 70-year-old woman with mental illness and numerous medical co-morbidities is presented. In addition, she had a history of cocaine abuse and a tortuous relationship with her husband. She presented to the medical and psychiatric emergency room numerous times with reported anxiety and various somatic complaints. She completed suicide by asphyxiation using a plastic bag two days after she was examined in the psychiatric emergency room and cleared for discharge where she presented with complaints of anxiety. Upon completion of an autopsy, homicide was ruled out.

Discussion: Suicide by asphyxiation/suffocation with a plastic bag, while rare, has shown a significant increase in the United States and worldwide. It is poorly understood and infrequently reported in the forensic literature. This presentation intends to alert the forensic community about this rare method of suicide and to educate mental health professionals about its increased incidence in the United States. Further, the goal is to review current methods of psychoeducating our patients about suicide and to expand on modalities currently in practice. In addition, this study will explore the physician's perspective of a patient suicide and the potential forensic implications.

Conclusion: The goal of this case is to add to the growing literature about suicide by suffocation and bring to light the need for future investigations to better understand what specific populations are vulnerable and at risk.

Suffocation, Suicide, Mental Illness

Questioned Documents Section - 2015

J1 Developments and Validations of TD-GC/MS and HPLC Methods for the Identification of Ballpoint Pen Ink Components: Study of Their Decomposition on Aging

Dilek Salkim Islek, MSc, Cerrahpasa Kampus, Fatih, Istanbul 34303, TURKEY; Esra Isat, BSc, Institute of Forensic Sciences Istanbul Univ, Cerrahpasa Kampus, Cerrahpasa cad. KMpasa fatih, Istanbul, TURKEY; Burak H. Gungor, MSc, Istanbul Üniversitesi Adli Tip Enstitüsü, Cerrahpasa Tip Fakültesi Kampüsü Fatih, Istanbul, TURKEY; and Salih Cengiz, PhD*, Istanbul Üniversitesi, Adli Bilimler Enstitüsü, Cerrahpasa Tip Fakültesi, Istanbul, 34300, TURKEY

After attending this presentation, attendees will learn how an ink entry on a questioned document relates to the origin date and explains how evidence is subject to aging.

This presentation will impact the forensic science community by validating the method of ink age determination using the dynamic physicochemical properties of the ink entries on a document.

Determination of the age of an ink entry from a questioned document is a difficult and controversial issue in forensic science. Currently, the study of ink age determination obtained from the dynamic properties of ink entries have shown that Phenoxy Ethanol (PE), which is one of the solvent inks included, has different behavior with respect to the varying thermal conditions of Thermal Desorption Gas Chromatography/Mass Spectrometry (TD-GC/MS) during methyl losses of the pigments and presents valuable confirmatory evidence of age using High-Performance Liquid Chromatography (HPLC).^{1,2}

New methods determining PE by TD-GC/MS and Crystal Violet (CV), Methyl Violet (MV), Tetramethyl Pararosaniline (TPR), and Victory Blue (VB) were developed and validated in this study. Validation parameters such as specificity, selectivity, intra-day repeatability, intra-laboratory reproducibility, inter-laboratory reproducibility, Limit of Detection (LOD), Limit of Quantitation (LOQ), and linear operating range and recovery were examined. LOD and LOQ values for PE are 10^{-10} ng/ml and 10^{-9} ng/ml, respectively. Operating ranges for CV, MV, TPR, and VB are 0.05-10 ng/ml, 0.5-10 ng/ml, 1-10 ng/ml, and 1-10 ng/ml, respectively. LOD and LOQ values for CV, MV, TPR, and VB are 0.02 ng/ml and 0.05 ng/ml, 0.3 ng/ml and 0.5 ng/ml, 0.5 ng/ml and 1 ng/ml, and 0.5 ng/ml and 1 ng/ml, respectively. For intra-day repeatability and intra-laboratory reproducibility studies, six repeated analyses were performed with solutions which have 2, 4, and 8 ng/ml concentrations. Standard deviations and relative standard deviation values of these analyses were calculated. These values were appropriate for the acceptance criteria. For inter-laboratory reproducibility studies, ink entries from six different documents were analyzed. 97.7% of MV and 100% of CV and TPR were recovered. This validated method for ink composition and age determination is specific, fast, and applicable.

Validation, TD-GC/MS HPLC, Ink Aging

Questioned Documents Section - 2015

J2 Carbon Black Nanoparticles and Graphene Oxide-Embedded Thin Sol-Gel Film for Analysis of Dye Molecules in Writing Inks by Laser Desorption/Ionization Mass Spectrometry

Seung-Hoon Bahng, MS, DIFS CIC Ministry of National Defense, 22, Itaewon-Ro, Yongsan-Gu, Seoul, Korea 140-701, SOUTH KOREA; and Sangwon Cha, PhD, Hankook University of Foreign Studies, 81, Oidae-ro, Mohyun-myeon, Cheoin-gu, Yongin 449-791, SOUTH KOREA*

After attending this presentation, attendees will understand how carbon black nanoparticles (Optical Mark Recognition (OMR) card marker ink) and Graphene Oxide (GO) used as matrices for ink analysis of questioned documents can lower the detection limits of dye molecules.

This presentation will impact the forensic science community by demonstrating how the small particles of GO have relatively lower matrix noise than conventional Matrix-Assisted Laser Desorption/Ionization (MALDI) matrixes such as 2,5-dihydroxybenzoic acid and how carbon black nanoparticles (OMR card marker ink) and GO have been widely used as matrices for Laser Desorption/Ionization (LDI) Mass Spectrometry (MS).

Carbon black nanoparticles have been used as a matrix for MALDI analysis of small molecules. For the application of the analysis method of forged document using the Surface-Assisted Laser Desorption/Ionization (SALDI), similar to MALDI, a study was conducted using the carbon black colorant as a tool to enhance the detection sensitivity of dyes such as Methyl Violet, Crystal Violet, and Rhodamine B in handwriting ink. This research focused on the chemical properties of the OMR card marker as a carbon black colorant. Through material analysis of these matrix and real-application tests, the carbon black ink from the most appropriate manufacturer was selected. As a result of testing the ink from multiple manufacturers, the CB1 ink was selected for its appropriate viscosity and excellence in its spraying performance. This study investigated the appropriate concentration needed for optimum conditions when applying the carbon black colorant. Depending on the organic dye, the optimum detection sensitivity appeared within the range of 1 ug/mL-100 ug/mL. In addition to the concentration of the dye, the efficiency of contact between carbon black colorant particles and dye molecules was a critical factor that could have an effect on the optimal condition.

Application of the results of this research to real handwriting ink strokes of unknown samples that have aged for a year found the detection sensitivity to be outstanding and capable of differentiation. Additionally, through the comparison of results, this method was found to be more reliable than the matrix agents such as 2-(4-Hydroxyphenylazo) Benzoid Acid (HABA). On the other hand, GO has more recently been widely used for a matrix of LDI/MS of small molecules because GO has a relatively lower matrix noise than conventional MALDI matrixes such as 2,5-Dihydroxybenzoic Acid (DHBA) and also because GO effectively ionizes some neutral molecules such as oligosaccharides, which are often difficult to ionize by conventional MALDI matrixes. However, use of carbon-based materials is not desirable for Time-of-Flight (TOF) MS since carbon nanomaterials stick to TOF electronics and, therefore, cause instability of the MS operation. In order to overcome this issue, GO-embedded sol-gel film substrates were developed for LDI/MS of small molecules. Results showed that the GO sol-gel film matrix substrate produced a much lower background noise than the aqueous GO particle matrix. This suggests that ablated carbon materials were significantly reduced when using the sol-gel film substrates. In addition, GO-embedded sol-gel film produced very clear and intense profiles of synthetic dye molecules in the region of m/z 100-800.

Graphene Oxide & Carbon Black, Laser Desorption/Ionization, Writing Ink Dye Analysis

Questioned Documents Section - 2015

J3 Frequency Occurrence of Handwriting and Hand Printing Characteristics

Ellen M. Schuetzner, BA, 6348 N Milwaukee Avenue, #161, Chicago, IL 60646-3728; Thomas W. Vastrick, BS*, 522 S Hunt Club Boulevard, Ste 217, Apopka, FL 32803; Mark Johnson, PhD*, UCF - Statistics Dept, University of Central Florida, Dept of Statistics, Orlando, FL 32816; and Kevin P. Kulbacki, MSFS*, Osborn & Son, 1273 Bound Brook Road, Ste 15, Middlesex, NJ 08846*

After attending this presentation, attendees will understand the most current statistical data available for demonstrating the uniqueness of handwriting in general and specific features.

This presentation will impact the forensic science community by providing answers to some of the commonly asked questions in courts across the country regarding information on the statistical basis for the uniqueness of handwriting.

A National Institute of Justice (NIJ) -funded research project began at the University of Central Florida in 2010. The purpose of the project is to provide statistical data as to the uniqueness of numerous handwriting and hand printing characteristics. This project was initiated by a group of document examiners who noted several court rulings in which judges admitted the forensic document examiner as an expert but noted that they were troubled by the lack of statistical support for the uniqueness claims by these examiners. This group met informally and outlined a research project that would help answer those questions. Eventually, the NIJ provided funding for this project and a formal research project under the administrative umbrella of the National Center for Forensic Science (NCFS) began. NCFS is a forensic research laboratory at the University of Central Florida that was uniquely qualified to provide the support necessary for such a large-scale project.

A project team was brought together to include forensic document examiners, statisticians, and database experts. It was decided that this project must be a statistical project about handwriting as opposed to a handwriting project about statistics. As such, the statisticians were empowered to develop the methodologies used in this project and had ultimate say in any methodology decisions. It was made quite clear, as a group, that accepted standard methodology practices were to be followed and described in detail in the final product. The team developed a stratified population sampling goal for the collection of handwriting specimens and used a previously developed handwriting form for this project. Numerous collectors were engaged to collect handwriting specimens in a random-based method but with the stratified goals in mind. Very limited direction was given to the collectors for purposes of randomness.

The initial selection of handwriting and hand printing characteristics underwent strenuous testing to establish that answers were neither subjective nor open to personal interpretation. Only features that tested with 100% agreement in a pilot test were retained in the final database. Classifiers categorized the handwriting specimens which were collected and tallied by the database expert, then the handwriting specimens were submitted to the statisticians for analyses. This presentation will reveal the results of those analyses, including frequency-occurrence ratios and the issue of interdependency in handwriting.

Handwriting, Statistics, Frequency Occurrence

Questioned Documents Section - 2015

J4 Natural Variation in Modern Handwriting

Jane A. Lewis, MFS, 544 E Ogden Avenue, Ste 700-289, Milwaukee, WI 53202*

After attending this presentation, attendees will have learned about the extent of natural variation in modern handwritten correspondence.

This presentation will impact the forensic science community by developing an appreciation for the range of natural variation that forensic document examiners can expect to encounter in their casework today.

Motivated by changes in modern handwriting due to more keyboarding at the computer, less cursive handwriting taught in schools, and more hand printing in general use, a study was conducted to determine the extent of the range of natural variation in modern handwriting. Natural variation results from each person's departure from the copybook handwriting system that they were taught in school. Natural variation is one of the basic principles of handwriting identification. No one writes exactly the same way twice. Appreciation for the range of natural variation in questioned and known writings helps forensic document examiners correctly identify or eliminate writers of questioned documents.

Envelopes bearing handwritten names and addresses from ten writers were collected from 2011 to 2014. The number of envelopes from the ten writers varied from two to seven. Most writers had three handwritten envelopes each. Also, the handwriting of three siblings was intercompared for the range of natural variation and the significant differences separating them. The differences proved significant even though the siblings grew up in the same house and learned to write in the same grade school. Handwriting considered from each envelope consisted of a first and last name, city name, state abbreviation, and zip code numerals. The number of times each letter of the name and additional address material appeared in the envelopes written by each writer was recorded along with the range of variation of the forms of each letter or number evaluated. Each of the 25 characters evaluated for each writer was rated N for narrow, M for moderate, or W for wide range of variation. The sample letters examined for their range of natural variation in the envelope writings of each writer revealed that these modern writers maintained a narrow to moderate range of natural variation. Only a few examples of a wide range of variation were observed.

Forensic document examiners consider many more features than basic letter construction in their typical examinations and comparisons than those considered in this study. The goal was to make an efficient assessment of natural variation in modern handwriting using limited features.

The samples are representative of everyday handwriting; however, they are possibly of a more formal writing style since they were written for clarity so that each could be delivered via the United States Postal Service system. Examples of the types of letter forms in the handwritten addresses from the ten writers will be demonstrated. This study will help forensic document examiners appreciate the degree of natural variation found in modern correspondence.

Natural, Variation, Handwriting

J5 Different Writer or Alternate Writing Style — A Case Review

Charles L. Haywood, MFS, 15751 Sheridan Street, #208, Fort Lauderdale, FL 33331*

The goal of this presentation is to review fundamental concepts related to features/characteristics observed in handwriting which form the basis for identification or elimination of an individual as the writer of questioned or disputed handwriting.

This presentation will impact the forensic science community by attempting to offer clarity to fundamental concepts used in evaluating and comparing handwriting features/characteristics resulting in a more accurate determination of authorship or non-authorship of disputed/questioned handwriting.

The validity of handwriting identification as a forensic science has been under intense attack by academics and legal critics for the past 30 years. In response, the forensic document examination community embarked on unprecedented research which focused on establishing that handwriting can be individualized and that properly trained individuals can associate handwriting that meets certain criteria to a specific individual with significantly greater accuracy than an untrained person.

One of the axioms of forensic document examinations is that two properly trained Forensic Document Examiners (FDEs) examining and comparing the same evidence should reach the same conclusion; however, in practice, it is not uncommon for two FDEs to examine the same evidence and render opinions that are diametrically opposed to each other. In some cases, the conflicting opinions may be caused by somewhat ambiguous evidence, which may be characterized as limited writing, highly stylized writing (e.g., signatures), or disguised questioned and/or specimen writing. However, if the questioned writing consists of multiple entries with many repetitions of the same words, letters, and/or letter combinations and the observed features/characters are consistent throughout the documents, the ambiguousness is less of a factor. Thus, two qualified FDEs with adequate specimens should arrive at the same conclusion regarding authorship. A case is being presented where this did not occur. The conclusions reached by the two examiners were essentially in direct opposition to each other. It goes without saying that one of the examiners made an error. This study presents one examiner's court presentations, the court's summary of evidence presented, and the court's findings (verdict).

Similarity, Variation, Fundamental Difference

Questioned Documents Section - 2015

J6 Development of Individual Handwriting Characteristics in ~1,500 Students: Statistical Analysis and Likelihood Ratios That Emerge Over an Extended Period of Time

Lisa M. Hanson, BS, BCA Laboratory, 1430 Maryland Avenue, E, St. Paul, MN 55106; and Kirsten A. Singer, MFS, Department of Veterans Affairs, OIG, Ofc of Investigation, 51L, 801 Eye Street, NW, Washington, DC 20001*

The goal of this presentation is to inform attendees that by collecting writing samples from school-age students and measuring individual characteristics as they develop (as students begin to stray from the copybook style), a true statistical model can be produced that scientifically proves why forensic handwriting comparisons are possible.

This presentation will impact the forensic science community by establishing that collected handwriting characteristic measurements can be used to statistically show how individual handwriting characteristics develop and how each person's combinations of these individual handwriting characteristics develop his/her own individual handwriting style.

Forensic handwriting examinations are often an important part of criminal and civil investigations and court testimony. Cases involving handwriting may include threatening letters, bomb threats, check fraud, homicides, and controlled substances. The need for research in the pattern-recognition sciences has been emphasized for years in many court decisions, articles, and reports, including the National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward*, published in February 2009.

The Minnesota Bureau of Criminal Apprehension (MNBCA) is conducting a study through a grant from the National Institute of Justice (NIJ) that will statistically analyze data from handwriting samples collected during the developmental stages of individual handwriting characteristics and well into adulthood. The MNBCA is currently gathering large amounts of handwriting and hand printing samples in order to measure individual handwriting characteristics (departures from the instructed copybook style) using a truthing tool from iFOX software developed at the State University of New York (SUNY), Buffalo, under the direction of Professor Sargur Srihari.

The first part of this study has already covered a three-year span with plans to continue collecting handwriting samples from the same students for up to 11 years in three-year increments.

Writing samples will continue to be collected every year from the same students, using the same words and phrases, from second grade through twelfth grade. The copybook style of writing is Zaner-Bloser, which is presently being taught in many schools across the United States.

Individual characteristics will be analyzed and measured as they develop over time, providing an extensive database of writing characteristics for each of the approximately 1,800+ students. This database size is instrumental in being able to run statistical time-model analyses that would lead to understanding many of the complexities involved during the act of writing. By collecting writing samples from school-age students and measuring individual characteristics as they develop (as the student begins to stray from the copybook style), a true statistical model can be produced that scientifically proves why forensic handwriting comparisons are possible. These measurements will be used to statistically show how individual handwriting characteristics develop and how each person's combinations of these individual handwriting characteristics develop their own individual handwriting style. It is these different combinations of individual handwriting characteristics that are the basis for the "theory" or explanation of why forensic handwriting comparisons are possible. This study will make it possible to support the "theory" with solid likelihood ratios that are scientifically accurate and reliable.

Handwriting, Development, Extended

Questioned Documents Section - 2015

J7 Development of a Supplemental Technique to Increase Visualization of Handwriting Indentations in Crumpled Documents With the Use of an Electrostatic Detection Device (EDD)

Kate Butler, BS, Florida Department of Law Enforcement, 1301 N Palafox Street, Pensacola, FL 32501*

After attending this presentation, attendees will consider using one of the supplemental techniques discussed in the presentation when presented with a crumpled or problematic document in which an indentation examination is necessary.

This presentation will impact the forensic science community by providing additional research in solving one of the common problems in EDD examinations.

Forensic Document Examiners (FDEs) receive questioned documents in a wide variety of conditions: chemically processed, folded, crumpled, wet, frozen, charred, wadded, or a combination thereof. Subsequently, upon receipt of a damaged document, FDEs are given the opportunity and, through much field research, the means to “unfold” the document’s secrets despite whatever state it may be in. Among the many examinations FDEs can employ, the application of an EDD is one of the key analyses performed on original questioned documents. These examinations have elicited superb information in the form of latent handwriting indentations as well as pattern impressions that may indicate a printing process which may otherwise have remained unseen; thus, the potential forensic information would not have been utilized. Crumpled or wadded documents have proven to be a problem in the area of EDD as the toner particles will typically adhere to the uneven and prominent creases and folds as opposed to the more subtle and delicate latent handwriting indentations or printing process impressions.

This research was designed to attempt to create a technique that would minimize the toner from adhering to the creases, thereby allowing the toner to potentially reach any of the latent indentations. The technique used two factors to attempt this: (1) increased humidity; and, (2) the application of a weight. These experimental factors were utilized separately and in combination on crumpled pieces of notebook paper containing latent handwriting impressions to determine their effects on an indentation examination. The crumpled papers were first examined with the EDD by applying the manufacturer’s recommended procedure, then re-examined with the EDD after applying increased humidity, pressure, or a combination of both. Images of the results of each indentation examination were captured with a digital camera for documentation. Once all of the experimental procedures were completed, the images obtained were examined to determine whether or not the visualization of handwriting indentations improved. A score was applied to both the “before” and “after” images based on specific criteria. Applying a higher humidity to the documents prior to EDD processing did allow for visualization of more latent handwriting indentations in the crumpled papers than if one had followed the manufacturer’s recommended procedure. A stretching technique was also attempted to see if this would cause any deleterious effects to the latent indentations. It was determined (using the guidelines followed in this research technique) that once a crumpled piece of paper had been exposed to increased humidity and then stretched by its edges, there was indeed an increased visualization of latent handwriting indentations with less interference from the creases and folds.

Indentation Recovery, Crumpled Document, Electrostatic Detection Device

Questioned Documents Section - 2015

J8 Cut-and-Paste Manipulation of a Quitclaim Deed

Farrell C. Shiver, MS, Shiver & Nelson Document, Investigation Laboratory, Inc, 1903 Lilac Ridge Drive, Woodstock, GA 30189*

After attending this presentation, attendees will have a greater awareness of how cut-and-paste manipulation may be used in the fabrication of a fraudulent document.

This presentation will impact the forensic science community by enhancing forensic document examiners' knowledge of how cut-and-paste techniques may be used in the fabrication of fraudulent documents and by providing a case example of an unusual document fabrication involving extensive use of cut-and-paste manipulation.

A quitclaim deed is a legal instrument that transfers one party's interest in real property (the grantor) to another party (the grantee). Quitclaim deeds are often used between family members to transfer property interests.

In early 2014, a father and son were involved in a civil suit over a piece of real estate. The father presented a copy of a quitclaim deed, allegedly signed by the son, granting the father interest in the property. The father also presented a copy of a second quitclaim deed which granted the son interest in the property. The father claimed the second deed was not genuine.

The son claimed the quitclaim deed presented by the father as genuine was actually fraudulent and that the document had been fabricated through a cut-and-paste manipulation of the genuine quitclaim deed. The son presented an original quitclaim deed for examination along with the copies of the documents presented by the father.

Subsequent examination of the documents produced by the son disclosed that the purportedly genuine quitclaim deed presented by the father had actually been produced by extensive cut-and-paste manipulation of a copy of the original quitclaim deed. A number of sections within a page and between pages were rearranged to change the father from the grantor to the grantee. The son was changed to the grantor rather than the grantee.

The cut-and-paste manipulation of the document was skillfully done. Due to the copy quality of the document, there was very little evidence of cut-and-paste on the document. Only one serious mistake was found. When the son's signature was transferred from the second page to the first page, a vestige of a short line was transferred with it. Other than this error, there was minimal internal evidence of the cut-and-paste manipulation on the document. Fortunately, the availability of the original document made the determination that the document had been fraudulently produced a relatively simple task.

Although it was not difficult to determine that the deed presented by the father was an altered version of the original, the difficulty would have been greatly increased had the original document not been available for examination. Without the original document for comparison, it would have been impossible to determine that a number of entries on the document were manipulated through cut-and-paste.

This presentation provides an example of the use of cut-and-paste techniques in an actual document and is also a cautionary tale for forensic document examiners.

Questioned Documents, Handwriting, Alterations

Questioned Documents Section - 2015

J9 Using Video Spectral Comparator (VSC) to Examine Documents Previously Subjected to Latent Print Examination

Robert H. Negherbon, MS, Pennsylvania State Police, 1800 Elmerton Way, Harrisburg, PA 17110; and Jennifer A. Ward-Trupp, BA, 1800 Elmerton Avenue, Harrisburg, PA 17110*

The goal of this presentation is to explain the use of the VSC to possibly uncover evidence from documents that have been subjected to latent print examination prior to being examined by a document examiner.

This presentation will impact the forensic science community by providing attendees with a better understanding of the illustrative view of study done in order to obtain evidence using the VSC on chemically treated papers.

In order to prevent irreparable damage to a document by other disciplines in the course of processing, forensic document examiners often request that they have access to documents prior to them being submitted for other more invasive procedures. Several other forensic disciplines use potentially destructive methods; DNA, serology, and latent print examinations all use methods that can hinder a subsequent document examination. This presentation will focus on latent print evidence examinations prior to submission for document examination. It will further explore one way to counter negative effects and still complete an efficient examination.

A common process in latent prints is the use of ninhydrin for latent print development. The chemicals contained in ninhydrin are destructive to documents in several ways, one of which is that the development of indented writing is highly unlikely once the paper has been submerged in any liquid, including ninhydrin. The paper will absorb the liquid and “puff out,” destroying any indentations that may have been present. Another way latent print processing can hinder document examination is when latent prints are developed, the purplish hue of the ninhydrin dye can hinder the forensic document examiner’s view of intricate details of the writing, such as pen lifts and striations. Ninhydrin can also cause certain types of inks to bleed. This bleeding can cause staining of the text on both sides of the document and could prevent forensic document examiners from being able to effectively and efficiently examine the document.

This presentation will focus on the process used to develop latent prints on paper, with special attention given to ninhydrin and the effects it has on ink. There will be a demonstration of both controlled samples and evidentiary documents examined in the lab with an explanation of what occurred when they were examined under various settings of the VSC. The goal of this presentation is to explore what can be done to recover evidence from a document when a questioned document examination is an afterthought. It will further raise awareness of how to use the VSC to recover evidence that may not otherwise have been observable. The inspiration for this project stems from a case that was received in the lab, after the document had already been processed with ninhydrin. The ink had run severely and it was extremely hard to read what was previously written on the document. After placing the document under the VSC and using various settings, much of the original text was able to be read and intricate details were observed.

VSC, Latents, Documents

Questioned Documents Section - 2015

J10 Conductive Inks and the Electrostatic Detection of Indentations

Kevin P. Kulbacki, MSFS, Osborn & Son, 1273 Bound Brook Road, Ste 15, Middlesex, NJ 08846*

After attending this presentation, attendees will understand the unique factors associated with conductive inks. Attendees will also learn what impact conductive inks can have on the development of indentations with electrostatic detection devices.

This presentation will impact the forensic science community by providing information about the theoretical and actual implications associated with specialty writing instruments that utilize conductive inks.

For more than 30 years, forensic document examiners have used electrostatic detection devices to develop latent indentations in questioned documents. These devices allow forensic document examiners to deposit an electrical charge on the questioned document. Indentations that are present on the document have been shown to have a different charge density than the remainder of the document. Through the application of charged toner particles, the forensic document examiner can develop the indentations in a manner that results in a visual transparency of the indentations.

Conductive inks have been available for several years; however, they have not become popular among the general public. Early conductive inks suffered from the inefficient transporting of electrical currents, hours of required drying time, and the need for a stiff base to which they must be applied. Recently, manufacturers have developed efficient water-based conductive inks that are deposited by a ballpoint pen. These inks are intended as educational tools for students to learn how to create basic circuit diagrams on plain paper. Through application with an ordinary pen and the application of magnetic attachments, it is possible to create a working circuit encompassing switches, resistors, and lights on a piece of paper. This advance in technology could lead to the more widespread use of specialty writing instruments that use conductive inks.

Conductive inks pose unique theoretical implications for the forensic document examiner. The development of indentations with electrostatic detection devices relies upon detecting different charge densities on a questioned document. Conductive inks, unlike ordinary inks, are designed to attract a charge. It is therefore theoretically possible that the charge density of the questioned document may be affected in a manner that is adverse to the development of indentations.

This research is being conducted to develop a deeper understanding of conductive inks. Furthermore, it is the purpose of this research to establish to what degree conductive inks affect the development of indentations with electrostatic detection devices. While it is unlikely that conductive inks will become the subject of a questioned document investigation in the near future, this research will provide a greater understanding of factors that could affect the electrostatic detection of inks.

Conductive Ink, ESDA, Indentations

Questioned Documents Section - 2015

J11 Case Studies of Simulated Security Features in United States Identity Documents

Hillary M. Hoover, MFS*, Immigration & Customs Enforcement, HSI FDL Stop 5116, 8000 Westpark Drive, Ste 325, McLean, VA 20598-5116

After attending this presentation, attendees will gain an understanding of current trends in simulated security features in plastic United States identity documents. Simulated laser engraving, embossing, and optically variable devices in the United States Border Crossing Card (BCC) and the United States Passport Card will be the focus of this presentation.

This presentation will impact the forensic science community by cultivating an awareness of how an identity document and its security features evolve as counterfeiters constantly find new ways to compromise current security features. The opportunity for most laboratories to study these advancements may be infrequent; therefore, this presentation will provide visual examples as well as methodologies for examinations leveraging a wide array of tools.

The United States BCC allows Mexican nationals to travel to and from the United States. The BCC cannot be used to gain employment or other benefits while in the United States. In order to obtain a BCC, an applicant must establish that they have ties to Mexico that would compel their return after visiting the United States.

The United States Passport Card permits United States citizens to travel between the United States, Canada, Mexico, the Caribbean, and Bermuda at land border crossings or sea ports of entry. This card may not be used for international air travel.

The United States BCC and United States Passport Card have been subject to countless attempts at unlawful replications and alterations over the years. With readily available access to digital printing methods such as thermal, inkjet, and laser printers, document mills have proliferated around the world. As a result, the United States government is constantly working to reinforce security of these documents to discourage and prevent those who seek to gain entry into the United States through unlawful means. Nevertheless, the Homeland Security Investigations Forensic Laboratory (HSI-FL) examines a multitude of counterfeit and altered United States BCCs and United States Passport Cards each year.

Plastic identity documents sometimes consist of polycarbonate layers receptive to laser engraving. These laser-receptive substrates react to the laser by altering the chemical composition of the card. This makes the removal of the laser-engraved data unlikely. Examples of altered United States BCCs and United States Passport Cards encountered in casework at the HSI-FL will be discussed in this presentation.

Security Features, Simulated, Laser Engraving

Questioned Documents Section - 2015

J12 Factors Affecting Electrostatic Detection Apparatus — 2 (ESDA2) Indented Writing Visualization

*Nina A. Harnarine**, BSc University of Toronto, 3359 Mississauga Road, Mississauga, ON L5L 1C6, CANADA; *John Jacobs*, BAA, York Regional Police Forensic Imaging Science Lab, 47 Don Hillock Drive, Aurora, ON L4G 0S7, CANADA; *Dave Juck*, York Regional Police Forensic Identification Unit, 47 Don Hillock Drive, Aurora, ON L4G 0S7, CANADA; and *Tracy Rogers*, PhD, University of Toronto at Mississauga, Dept of Anthropology, Mississauga, ON L5L 1C6, CANADA

After attending this presentation, attendees will gain a better understanding of factors affecting the ESDA2 visualization of indented writing, including paper type, the writing utensil used on the original document, relative humidity of the sample, and the ESDA2 toner development method.

This presentation will impact the forensic science community by providing a comprehensive guide containing the optimum conditions for recovering indentations on different paper types using the ESDA2. Document examiners will no longer waste time and resources nor will they potentially lose valuable evidence attempting to obtain the best conditions for visualizing indented documents through trial and error.

The ESDA2 develops indented impressions which are created when pressure is applied to the original document. Indentations on papers below the original are due to paper fibers breaking. This “invisible” writing provides valuable information about a case, missing person, etc., and even generates handwriting samples.

Past research has yielded poor results for coated paper, but the potential factors responsible for its poor performance have not been systematically examined.¹ Recycled paper is now commonly used but has not been investigated in previous studies. The goals of this study are to maximize the visibility of indentations with ESDA2 on bond, recycled ruled, glossy, and recycled bond paper controlling for three relative humidity levels (50%, 60%, and 70%) and to test three ESDA2 development techniques: Aerosol, Cascade, and Toner Application Device (TAD).

The relative humidity of indented documents prior to ESDA2 development has been examined in various studies.²⁻⁶ James’ and Noblett’s research determined that the best quality indentations were observed when documents were humidified between 40%-60%.³ Baier stated, the more coated the paper, the more time it takes to humidify the paper to obtain a clear visualization of the indented writing with the ESDA2.² Indented documents’ relative humidity in the ESDA2 development is important. This research will determine the best humidity level for different paper types.

The development method is an additional factor to consider when examining ESDA2-developed indented documents. Research has been conducted on the Aerosol and Cascade Methods.^{3,4} Baier concluded, Aerosol works best on the top sheet (sheet directly below original document) and when the indentation is clear, in contrast, Cascade was more efficient than Aerosol at developing weaker indentations.² James and Noblett determined Aerosol produced a higher quality score than Cascade, independent of paper type or amount of pressure applied.³ Past research on ESDA2 toner-development methods have produced conflicting results. No research has been performed on the efficiency of the TAD technique in developing indented documents. This research will determine which ESDA2 development method produces the clearest visualization of indentations on different paper types.

A total of 1,080 indented documents were prepared using three writing utensils (ballpoint pen, gel pen, and mechanical pencil) on four paper types (bond, recycled ruled, recycled bond, and glossy). The samples were divided into subsamples of 30 and each subsample was subjected to different humidity levels (50%, 60%, or 70%). Each document was placed within the ESDA2 capacitor and charged. One toner development method (Cascade, Aerosol, or TAD) was applied per document (360 samples for each toner development method). A quality score from zero (no words visible) to four (all words and small details visible) was recorded. The Kruskal-Wallis test followed by Wilcoxon Signed-Rank Test with a Bonferroni Correction was applied to the data. The samples composed with the ballpoint pen had the highest quality score ($p = 1.12 \times 10^{-6}$). It is recommended that ESDA2 control indentations are composed with ballpoint pens for the original sheet. The optimum conditions for the paper types were: (1) bond paper (70% and Aerosol ($p < 4.00 \times 10^{-8}$)); (2) recycled ruled (60% and Aerosol ($p < 1.32 \times 10^{-3}$)); (3) recycled bond (60% and Aerosol ($p < 5.60 \times 10^{-3}$)); and, (4) glossy (60% and Aerosol ($p < 6.30 \times 10^{-5}$)). Based on this study, ESDA2 visualized indentations will be the clearest when recycled ruled, recycled bond, and glossy paper are humidified at 60%, while bond should be humidified at 70%; the Aerosol development method should then be applied across all paper types.

J13 Analysis Techniques of Plastic Identity Documents

Stephanie A. Kingsbury, MFS, 8000 Westpark Drive, Ste 325, McLean, VA 20598*

After attending this presentation, attendees will gain a better understanding of new trends in plastic Identity Documents (IDs) and analysis methods by which to visualize and classify the materials used in their production.

This presentation will impact the forensic science community by: (1) increasing awareness of plastic IDs and of non-destructive/destructive analysis testing methodologies as a means of counterfeit deterrence and adversarial analysis; and, (2) identifying and highlighting tamper-resistant and copy-proof security features and printing incorporated within contemporary plastic IDs.

IDs are produced for and used by people around the world for a variety of different purposes, including proof of identity, employment eligibility, evidence of driving privileges, and domestic and international travel. IDs function as the link between an individual's government-verified biographical data (including, for example, date of birth, nationality, and sex) and the individual himself. These documents must be inherently secure and tamper evident to maintain public confidence and trust.

IDs can be manufactured in many different ways with a variety of types of plastic, including polycarbonate, Poly-Vinyl Chloride (PVC), Polyethylene Terephthalate (PET), or a combination of these and others. These plastics are combined with heat, pressure, and/or adhesives to create an overall card body that guards against tampering or alteration. In addition, security inks, Optically Variable Devices (OVDs), and Radio Frequency Identification (RFID) devices are incorporated within plastic documents as a deterrent against counterfeiting because they are difficult to replicate successfully. In addition, commercial availability of similar products and the knowledge of translating these products into counterfeit IDs are imperative for the manufacturer and designer to contemplate before placing a security feature into a document. Security printing is another important consideration in the manufacture of plastic identity cards; this includes personalization techniques such as laser engraving that discourage counterfeiters from replicating or compromising these methods.

Sophisticated non-destructive and destructive techniques that may be utilized to determine whether or not an ID is genuine will be explored. Non-destructive techniques include digital microscopy, which may be used to: (1) visualize plastic identity cards' security features from a 3D, depth-up perspective; (2) measure the relative heights of these features; and, (3) even classify the internal card body structure. Fourier Transform Infrared Spectroscopy (FTIS) is another non-destructive technique that allows the chemical composition of a variety of plastic substrates to be elucidated quickly and efficiently. A destructive technique that has been utilized at the laboratory in counterfeit deterrence analysis is card cross sectioning, which is achieved by cutting the card at a predetermined point of interest, mounting the card in an epoxy-resin mixture, polishing, and analyzing it with the Scanning Electron Microscope (SEM). Elemental techniques such as Energy-Dispersive X-Ray Spectroscopy (EDS) may then be employed to probe specific areas within the card body, such as the RFID, to ascertain an accurate elemental composition that was used in the card body construction.

Plastic, Identity Documents, Counterfeit Deterrence

Questioned Documents Section - 2015

J14 Are the Principles of Forensic Signature Identification Corroborated by an Analysis of Digitally Captured Biometric Data?

William J. Flynn, BS, Affiliated Forensic Laboratory, 3030 N Central Avenue, Ste 1206, Phoenix, AZ 85012; and Kathleen Annunziata Nicolaidis, BA, Affiliated Forensic Laboratory, 3030 N Central Avenue, Ste 1206, Phoenix, AZ 85012*

After attending this presentation, attendees will have learned the results of a study of biometric signature data of both authentic and non-authentic signatures. Analysis of this data is being conducted to determine if the tenets of handwriting identification, derived from more than 100 years of study, observation, and experience, can be supported quantifiably by biometric data collected during signature execution.

This presentation will impact the forensic science community by providing objective evidence regarding signature characteristics such as speed, rhythm, and natural variation, characteristics forensic document examiners consider when determining a signature's authenticity. Although a vast body of literature exists stating speed and rhythm are significant indicators of genuineness or lack thereof, the advent of digital signature pads provides an opportunity to compare the quantifiable data of these characteristics in both genuine and non-genuine signatures. Biometric data also allows for analysis of the signatures from one writer to determine the presence and extent of natural variation.

Data from over 100 digitally captured signatures were studied to prove or disprove the following hypotheses: (1) there will be quantifiable differences between signatures written naturally and unnaturally (simulated or traced); (2) there will be quantifiable differences in signatures executed by different writers; and, (3) there will be quantifiable differences in naturally executed signatures of one writer.

Signatures were collected using a Topaz® signature pad. A piece of paper was placed on the pad and subjects were asked to sign multiple times using a pen stylus. This allowed for the simultaneous collection of both wet-ink and digital signatures. Subjects were asked to provide multiple samples of genuine signatures, simulated signatures, and traced signatures.

Data from naturally and unnaturally executed signatures are compared. Both intra- and inter-writer comparisons are also conducted. This presentation will analyze the results of this study.

Biometric Signature, Natural Variation, Handwriting Principle

Questioned Documents Section - 2015

J15 The Universal Coded Character Set (ISO/IEC 10464) and the Unicode Standard as Aids to Forensic Document Examination in an International and Transnational Environment

Peter V. Tytell, BA, Forensic Research, LLC, 15 Maiden Lane, Ste 308, New York, NY 10038-4017*

The goal of this presentation is to provide attendees with an awareness of developed standards, their potential benefit, and how to acquire and use them.

This presentation will impact the forensic science community by increasing awareness of, and the ability to deal with, non-English material.

Generations of American forensic document examiners have been well aware of the writing habits that successive waves of immigration brought to our shores and how these habits might carry over to the writing of these immigrants and even their descendants. These factors are still relevant today, but given the globalization of commerce, crime, and terrorism as well as the nature of contemporary internet society and social media, the 21st-century examiner can be confronted with documents from any part of the planet, perhaps in languages that use the Latin alphabet but with characters not seen in English, or even in languages with variants of completely different scripts. Such problems can arise in civil actions over a contract or a will; in criminal cases involving smuggled goods, drug records, or human trafficking; or in the context of a civil disaster like a train accident or airplane crash.

Signatures, handwritten text, or printed matter could be involved. What might seem to be an illegible, highly stylized, and personalized symbolic signature could actually be the completely legible and unremarkable writing of a name in an unfamiliar script. While it is sometimes appropriate to undertake the examination of a foreign text with the aid of a translator, the language must first be determined before the appropriate translator can be sought. A document examiner who can use a limited amount of “weird or foreign” text to provide a stymied investigator with information about the language of contraband packaging, the phone numbers in an address book, the message on a smartphone screen, or the charred remains of a receipt or newspaper clipping in a victim’s pocket might make a truly significant contribution to the resolution of the case.

The goal of this presentation is to familiarize examiners with the **International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 10464**, the Universal Coded Character Set (UCS), and the Unicode Standard. These are standards developed for data exchange that provide unique names and code identifiers for the characters of the world’s written languages (including some long dead) as well as for many additional symbols.^{1,2} The responsible ISO Working Group has coordinated with the Unicode Consortium for more than 20 years and the two standards are essentially compatible, though Unicode includes much more information and some of the additional features are required for full implementation.

These standards provide internationally accepted naming conventions for characters and symbols, including diacritics, accented characters, digraphs, and new forms that extended the Latin alphabet for use with diverse languages worldwide. Searching the extensive Unicode Code Charts can provide useful leads regarding the language or language group using one of these modified characters or a combination of characters. Potentially useful information can also be found for languages using versions of the Cyrillic or Arabic alphabets and other writing systems.

Specific illustrations and internet search strategies will be provided.

Questioned Documents Section - 2015

J16 Collaborative Radiography (and Other Interdisciplinary Activities) Between Document Analysts and Forensic Anthropologists at the FBI Laboratory

*Angi M. Christensen, PhD**, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; *Gabriel D. Watts, BA*, Questioned Documents Unit, Rm 2160, 2501 Investigation Parkway, Quantico, VA 22135; and *Gregg Mitchell Mokrzycki, BA, MFS*, 2501 Investigation Parkway, Quantico 22135

After attending this presentation, attendees will understand some of the myriad uses of radiography in forensic science, including ways the same technology can be used for different forensic applications within a laboratory.

This presentation will impact the forensic science community by highlighting ways in which different forensic disciplines (specifically, questioned documents and anthropology) can work together to achieve results.

Since the discovery of X-rays in 1895, radiography has become a routine means of non-invasive examination of internal structures and composition of various objects and materials. Wilhelm Conrad Roentgen, who first discovered X-rays, further discovered that X-rays would penetrate most solid matter, but leave shadows of denser materials including bones and metal. Radiography first became widely used in medicine and dentistry, but other industrial uses followed in the early 1900s. Radiography is currently used in various industries including engineering, automobile safety, and food safety, among others. Of particular interest is the fact that radiography is also widely utilized in a variety of forensic science applications. Although often associated with medical imaging and diagnostics of human bodies by forensic radiologists and pathologists, radiography has many other forensic uses. Forensic anthropologists commonly use radiography in the examination of skeletal remains. Radiography is also used in forensic metallurgical examinations to reveal interior construction or the presence of defects, cavities, or foreign material within an object. It can be used to examine the internal components of explosive devices and to reveal the contents of envelopes, bags, and packages without having to physically open them.

In the interest of fiscal responsibility, equipment-sharing between various units at the Federal Bureau of Investigation (FBI) Laboratory is encouraged when possible. One seemingly unlikely, but ultimately highly successful, partnership recently developed between the Questioned Documents Unit and the Forensic Anthropology Program due to their shared forensic radiography needs. Radiography is used in the FBI Laboratory for document examination to view watermarks, detect concealed communications, view/confirm identity document security features, or determine whether collectors' items such as autographed baseballs have markings or construction details that support or refute their authenticity. In anthropological examinations, radiography is used to detect and locate foreign materials such as bullets and dental restorations, to assess skeletal trauma, and to estimate biological parameters such as sex and age. While many radiography units may be best suited to a specific medium of study, one system was found to serve both units very effectively. The system is a cabinet-style, self-contained unit constructed on a mobile platform. It utilizes a high-resolution X-ray source with an energy range of 10-130Kv, with available detector sizes ranging from 2"x2" to 17"x17". User-friendly touch-screen controls allow for post-processing enhancements such as contrast adjustments that allow examiners to further exploit areas of interest. Being a self-contained and self-shielded unit, no additional shielding (either in the location of use or for personnel operating the machine) is required. Digital radiographic images can be easily saved in a variety of formats.

This presentation will provide a pictographic overview of various uses of this radiography technology in the FBI laboratory. In addition, other previous and potential collaborations between document analysts and anthropologists within the FBI Laboratory will be discussed.

Forensic Radiography, Questioned Documents, Anthropology

Questioned Documents Section - 2015

J17 Characterization and Discrimination of Inkjet Printer Inks Using Micro-Raman Spectroscopy

Patrick Buzzini, PhD*, West Virginia University, 1600 University Avenue, 304, Oglebay Hall, PO Box 6121, Morgantown, WV 26506-6121; and Alyshia Katherine Meyers, BS, West Virginia University, 208 Oglebay Hall, PO Box 6121, 1600 University Avenue, Morgantown, WV 26506-6121

After attending this presentation, attendees will understand the potential of micro-Raman spectroscopy to detect *in situ* chemical information from micrometric-colored spots of inkjet-printed documents from different sources.

This presentation will impact the forensic science community, with emphasis toward questioned document examiners, by exploring the chemical properties of inkjet printer inks, particularly non-extractable pigment-based samples. An example involving the counterfeiting of banknotes will be developed.

Inkjet printers are ubiquitous common devices used in various everyday activities. Due to their relative low cost and accessibility, it is not surprising that inkjet-printed documents are used for different illicit activities, including the production of counterfeited banknotes.

The printing process involves the production of a constellation of micrometric colored spots. This form of evidence makes Raman spectroscopy a suitable method for their rapid *in situ* detection, thus avoiding any extraction procedure. The Raman technique detects the phenomenon of light scattering from samples that are excited with an intense irradiation source, such as a laser. Colorants (i.e., dyes and pigments) are known to be strong Raman scatterers. While micro-Raman spectroscopy has only recently gained interest in forensic laboratories, this technique has already demonstrated its potential to be a useful method for ink analysis, especially in cases where ink extractions are not successful (i.e., pigment-based inks such as gels).

The goal of this research effort is to implement a non-destructive and relatively rapid analytical procedure for the *in situ* detection of microscopic ink spots produced by colored inkjet printers in order to help identify a (list of) printer source(s) from unknown printed specimens. For this research, the micro-Raman spectrometer is utilized to determine whether inkjet printer inks from different brands and models can be differentiated by means of their detected chemical profile. The inter-source variation of the obtained chemical profiles is studied by considering Raman data from cyan, magenta, and yellow spots. The approach consists of evaluating what colors are the most discriminating ones and if there are dependencies between these three variables, given a particular brand and model.

As a preliminary step for this project, 135 Raman spectra were captured from nine inkjet printer ink samples as well as from a counterfeited banknote, which was obtained from the collection of the Criminal Investigative Division, Treasury Obligations Section of the United States Secret Service. Extraction with methanol was carried out on all ink samples to determine if the ink was dye-based or pigment-based. Extractions were conducted on samples representing the three individual colors separately. Then, all samples were processed *in situ* on a printed document using a Near-Infrared (NIR) laser wavelength at 785nm. Cyan, magenta, and yellow spots were focused for each sample using a 50x objective lens. Five replicates per sample were obtained to verify the repeatability of the spectra. The resulting spectra were pre-processed via baseline correction, normalization, Multiplicative Scatter Correction (MSC), and Standard Normal Variate (SNV) transformation. After pre-processing, identifications of the colorants used in the ink were attempted by comparing them to a house-made reference spectral library. Data analysis of the Raman spectra was conducted using Principal Component Analysis (PCA) and Hierarchical Cluster Analysis (HCA) in order to explore the inter-variability of the ink colors. Linear Discriminant Analysis (LDA) was carried out on the counterfeit samples to implement the structure of a system that, once a representative number of spectra is obtained, will classify the spectra with the purpose of inferring the potential brand(s) and model(s) of the inkjet printer(s) based on similar Raman profiles.

Questioned Documents, Raman Spectroscopy, Inkjet Printer

Questioned Documents Section - 2015

J18 A Novel Automated, Searchable Database for the Chemical Characterization and Comparison of Printing Inks

Tatiana Trejos, PhD, Florida International University, Chemistry Dept, 11200 SW 8th Street, University Park, OE 109, Miami, FL 33199; Peter Torriano, PhD, CoVar Technologies, 1495 Chain Bridge Road, Ste 100, McLean, VA 22101; Ruthmara Corzo, BSc, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Paul Martin, PhD, CRAIC Technologies, 948 N Amelia Avenue, San Dimas, CA 91773; Anna Raeva, PhD, 11200 SW 8th Street, CP194, Miami, FL 33199; Kiran Subedi, 1191 NW 7th Court, Apt 2, Miami, FL 33136-2331; Rhett J. Williamson, 1100 SW 104th Court, Apt 302, Miami, FL 33174; Jong Yoo, PhD, 46665 Fremont Boulevard, Fremont, CA 94538; and Jose R. Almirall, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will be informed about a new database that was created for the automated search and comparison of printing ink evidence. The database contains spectra from the following six analytical methods using standardized acquisition parameters for each method: (1) Attenuated Total Reflectance Fourier Transform Infrared (ATR/FTIR) spectroscopy; (2) Raman spectroscopy; (3) Scanning Electron Microscopy with Energy Dispersive Spectroscopy (SEM/EDS); (4) Pyrolysis Gas Chromatography/Mass Spectrometry (Py-GC/MS); (5) nanosecond Laser Ablation Inductively Coupled Plasma/Mass Spectrometry (ns-LA-ICP/MS); and, (6) Direct Analysis in Real Time Mass Spectrometry (DART[®]-MS). The relative discrimination and overall performance of the database search routine, including error rates (false associations and incorrect discrimination), are reported for the first time for each of the six analytical methods that make up the chemical database as well as for combinations of the data (data fusion). Attendees will gain knowledge on the relative utility and performance of these analytical methods for the examination of different types of printing inks.

This presentation will impact the forensic science community by providing a comprehensive evaluation of the performance of a searchable database that was designed and validated as a tool to augment the chemical information mined from ink evidence and to aid in document examinations and related investigations. The software will become commercially available for use and it is expected that the database will expand with the number of users, making the database increasingly useful through the continuous feedback from examiners.

The database contains two main sets of data: the reference database and the training or testing database. The reference database currently contains 4,658 data files acquired from representative samples from selected printing sources to account for some of the global variety in printers, including 319 toner, inkjet, offset, and intaglio inks. The testing database contains over 800 data files acquired from 45 duplicate control samples used to train the searching algorithms. Duplicate controls were analyzed over different days to evaluate correct associations and to assess the potential for instrumental variation, operator variation, and within-sample heterogeneity.

The developed software makes use of machine-learning algorithms for classification and comparison of unknown samples to the database collection, in particular Partial-Least Squares Discriminant Analysis (PLSDA) and K-Nearest Neighbor (KNN) spectral comparisons. The search algorithms generate similarity scores that permit the operator to significantly narrow down the possible sources of ink samples contained within the database. The user may select to use any number of methods depending on the case, type of ink, sample size, or other factors. Data fusion algorithms were also built into the database to allow for data fusion from two of any of the analytical techniques, often providing improved performance for fused data searches over searches using any technique in isolation. The relative discrimination of all the analytical methods has been determined for each ink type. LA-ICP/MS provides the best discrimination (>99%) and py-GC/MS provides the least information, regardless of ink type. The discrimination capability of SEM/EDS was relatively poor for inkjets and offsets but was found to be good for toner and intaglio samples, with discriminations of 97.2% and 98.2%, respectively. Although FTIR and Raman provided lower discrimination capabilities, they are useful for characterization of major organic components and classification or grouping of inks.

A validation study of the database search algorithms, using blind searches of duplicate controls, reveals that LA-ICP/MS and FTIR data searches result in the best performance for associating duplicate samples analyzed by different operators on different days with >90%-100% of duplicate pairs correctly associated. DART[®]-MS data search results in 83%-100% of the duplicate pairs correctly associated, with the other analytical techniques resulting in 33%-100% correct associations for SEM/EDS and 6%-81% for Raman, respectively. The lower correct association performance is often related with a limited number of duplicate controls available in the current testing database for particular sensors and/or particular limitations of certain techniques for some types of ink.

Questioned Documents Section - 2015

Although the current collection set represents a relative small snapshot of the printing inks universe, it serves as a proof of principle of its potential utility and relevance in the field. This novel chemical database now provides a comprehensive inorganic and organic characterization of different printing inks and permits data fusion of the multiple sensors.

Printing Inks, Database, Data Fusion

Questioned Documents Section - 2015

J19 Computer-Scored Test Answer Marks, A.K.A. Bubble Marks: How Individual Are They?

Janet F. Masson, BJ, 908 Town & Country Boulevard, Ste 120, Houston, TX 77024*

After attending this presentation, attendees will better understand what can and cannot be determined from the examination of bubble marks. Attendees will also learn how to make an examination of such marks.

This presentation will impact the forensic science community by presenting the results of research about examinations of marks not previously studied but coming under scrutiny in recent lawsuits.

Over the years, many document examiners have inspected standardized tests on which handwritten answer marks are used. In these cases, there is commonly a concern about whether cheating has occurred. This cheating can take many forms, including, but not limited to: (1) the use of impersonators (a student sending in a proxy or impersonator to take the exam on his/her behalf); (2) swapping of tests and answer sheets by two persons in the same room; or, (3) making after-the-fact changes to specific answers or completing unanswered blanks on an answer sheet in order to increase a student's or school's score. In fact, a survey of newspaper articles written over the last few years reveals numerous reports of alleged large-scale cheating on standardized tests across the country.

Standardized answer sheets are used for obtaining information in a format that allows answers to be counted or scored electronically. While such forms are often used to obtain answers on standardized tests, they are also sometimes used for surveys and ballots. The pencil marks made to indicate answers or choices on these forms are called grid marks, bubble marks, or simply answer marks.

Typically, when a document examiner receives one or more standardized answer sheets for examination, the document contains at least some general handwriting, possibly one or more signatures, and often handwritten numeric calculations. Examination of this writing is a typical, straightforward process discussed in many textbooks on document examination and covered by relevant standards in the field. Furthermore, considerable research has been conducted regarding identification of signatures, hand printing, and numerals. Yet sometimes the questions about a test answer sheet, survey, or ballot can only be resolved by the evidence in the answer marks themselves.

The literature on document examination contains little if any discussion of the limited subject of handwritten answer marks on standardized tests as well as those on ballots and surveys. This project was designed to study these answer marks or "bubble marks" from the perspective of the forensic document examiner.

In this project, samples of answer marks were obtained from more than 100 participants. The questions studied were: (1) how answer marks should be examined; (2) whether any or all writers have a consistency in making answer marks; (3) whether answer marks have individuality; (4) what conditions need to exist in order to reach a meaningful opinion about these marks; and, (5) what opinions can be reached from the evidence found in answer marks.

Handwriting, Bubble Marks, Standardized Test Answer Marks

Questioned Documents Section - 2015

J20 Another Look at Ink and Toner Intersections: A Word of Caution

Laura A. Mancebo, BS, Applied Forensics, LLC, 1975 Hempstead Turnpike, Ste 407, East Meadow, NY 11554; and Dennis J. Ryan, MBA, 1975 Hempstead Turnpike, Ste 407, East Meadow, NY 11554*

After attending this presentation, attendees will understand how to conduct an examination of the intersection of toner and ink on a paper substrate. Attendees will understand techniques that will assist in the intersection examination. Attendees will also understand that caution is needed when drawing conclusions from the examination of the intersection of the toner and ink.

This presentation will impact the forensic science community by serving as a “wake-up” call when drawing conclusions from the examination of ink and toner intersections. This presentation will impact examiners by making them more cautious when drawing conclusions in this type of examination.

Factors considered in an ink/toner intersection problem include the writing instrument, the paper substrate, and the writing surface. Different writing instruments will be discussed, including ballpoint, roller ball, gel pens, and felt tip/porous point pens and their effect on drawing any conclusions.

Is spectral reflectance from the ink a critical factor in arriving at a conclusion? Can spectral reflectance dissipate over an extended period of time, thus inhibiting the examination? Is the spectral reflectance phenomenon a critical factor in drawing any conclusions?

Other facts that are considered are the paper substrate and its effect on the ink/toner examination. Does that substrate affect the possibility of making any determination? A look at the effect of the writing surface is also a factor to be considered in this type of examination. This presentation will look at the factors needed to make a definitive conclusion as to the sequence of the ink over toner or toner over ink. Examiners may be “tricked” by the observations they make. Can the luminescent properties in the ink assist in making the sequence determination?

These types of examinations are critical in cases where a document has been called into question as to whether an addition has been made to the document after it has been signed. If there is no toner/ink intersection, it is very difficult to make any determination. If the toner and ink has intersected, some conclusions may be drawn as to which came first, the ink or the toner. In most cases, where the toner lies over the ink, this may be a significant factor in determining if the document has been altered. If the toner shows evidence of being crushed by the trough of the pen, this may be evidence of the toner being present when the document was signed.

In conclusion, this presentation will look at what evidence should be present to make any definitive conclusion and whether spectral reflectance and any presence of luminescent properties in the ink are needed to make any determination.

Intersections, Sequencing, Toner

Questioned Documents Section - 2015

J21 The Origin of a Tracing

Donald D. Moryan, BS*, 4930 N 31st Street, Forest Park, GA 30297

After attending this presentation, attendees will have a better understanding of how signature tracings are created.

This presentation will impact the forensic science community by showing examination techniques involving traced signatures.

This presentation details a case study regarding a life insurance document in which the beneficiary information was allegedly changed. The authenticity of the principle signature was in question. Examination revealed the signature was spurious and possibly a simulation or a tracing of a genuine signature. At first glance, the questioned signature appeared to be spurious. It contained many features associated with a simulation/tracing of a genuine signature. Unnatural movement and the apparent lack of speed in writing was present. The signature also was of poor line quality and contained pen lifts. Blunt beginning and ending strokes were present as well. Further inspection revealed the questioned signature was pictorially similar to the victim's standard signatures that were provided. The signatures were so similar that detailed scrutiny of each known signature was warranted to ascertain if indeed one of them was used as a possible model for the questioned signature.

The examination revealed that one known signature and the questioned signature looked remarkably alike. Microscopic examination of the questioned signature did not reveal any of the typical signs of a tracing, such as pencil or carbon remnants nor any indented lines. Also, examination of the original standard signature did not reveal any such evidence. Overlaying the questioned and known signatures proved the questioned signature was a tracing of the known signature. Examination of one of the known documents with oblique lighting techniques revealed indented lines adjacent to letters of the first name. These indentations corresponded exactly to the questioned signature. This proved the known signature was used as the model for the questioned signature. The tracing was undoubtedly made with the use of transmitted light. This would account for the stray indented lines on the known document. Conclusions that can be drawn from this examination are: (1) the questioned signature is a tracing; and, (2) the signature appearing on the bottom of the copied emergency data record was the model used to make the questioned signature.

Determining authorship was another matter. Traced signatures contain no evidence of their writer as the following of a written line has nothing to do with natural writing. They do not contain handwriting characteristics of their maker and therefore are not identifiable. Therefore, in this case, no opinion could be made on the maker of the traced signature. Even if no conclusion regarding authorship could be made, the discovery of the model signature is very important, even though forgery can be proven without locating the model signature.

Tracing, Simulation, Model Signature

Questioned Documents Section - 2015

J22 Document Examination For Non-Document Examiners

Gregory A. McNally, BS, 20 Whispering Sands Drive, Apt 501, Sarasota, FL 34242-1667*

After attending this presentation, attendees will be able to give presentations to non-document examiners that engage their attention by presenting an interesting selection of document examinations and by interjecting experiences and anecdotes of unusual and many-times entertaining situations which have occurred.

This presentation will impact the forensic science community by allowing the document examination community to inform the public, in an interesting manner, of analyses which are performed. This may also open the door to additional requests for document examination services.

Everyone has sat through their share of boring presentations. It's mind-numbing to be forced to listen to dry content that's delivered (or worse, read) at one, rather than discussed with one. Often, all this talking is in vain. Research has shown 91% of listeners at presentations admitted to daydreaming and an impressive 39% admitted to actually falling asleep at some point.

This presentation will demonstrate how to inform the audience that you encourage their questions, that you expect interaction, the types of questions you'll entertain, and when these questions should be presented. Also discussed will be when to present from the stage and when to intermingle with the audience as you present. During the presentation, discuss real-life situations surrounding document examinations. This would include circumstances which may have occurred prior to being retained, during the examination and testimony, and additional information that transpired after the matter was resolved. Some examples in this presentation consist of cases including Leona M. Helmsley, the Andy Warhol estate, and the "handwriting on the bathroom stall." These often-humorous anecdotes have previously entertained audiences.

Hopefully, at the conclusion of this presentation, attendees will be aware of tactics that not only inform their future audiences about document examiners' duties but are also entertaining, thus making their presentations memorable experiences.

Document Examination Review, Non-Document Examiners, Entertaining

Questioned Documents Section - 2015

J23 Addressing Admissibility Challenges to Forensic Document Examination From Both a Federal and a State Examiner's Perspective

Carl R. McClary, BA*, 2600 Century Parkway, Ste 410, Atlanta, GA 30345; and Karen J. Nobles, BA*, Forensic Document Examinations, PO Box 411, Pensacola, FL 32591-0411

After attending this presentation, attendees will have gained an understanding of the discovery requirements of witnesses in federal criminal or civil cases with respect to Rules 16 and 26. Examples of required information will be given in addition to material that can be helpful in thwarting an admissibility challenge. *Daubert* and *Frye* states will be identified and recent admissibility rulings will be discussed.

This presentation will impact the forensic science community by providing samples of discipline-specific information that can be appended to required material to preclude an admissibility challenge. This information will also assist in educating the legal community on the questioned documents discipline's recent history of challenges and provide the basis for how the discipline meets the factors found in *Daubert*.

The questioned documents discipline was the focus of many reliability challenges in the mid- to late-1990s and early 2000s. Those same challenges are still being utilized by defendants, although to a lesser extent, even though Federal Appeals Courts in every circuit have ruled in favor of admitting this type of testimony. The presentation will address the latest and most popular wording in motions that have been filed in the hopes of challenging some of these appellate rulings by creating new areas of doubt. It will provide guidance in the prevention of these challenges through preliminary discovery filings as well as providing material for formal responses to those motions that have already been received. Recent rulings will also be given to include, one in the state of Florida which adopted the *Daubert* standard for admissibility in 2013. Language from the ruling in this case, which is the first challenge of this type since the adoption of the standard in Florida, will be discussed including that court's observance that the *Daubert* standard was intended to be more flexible than the *Frye* standard with respect to scientific testimony. Although not required, other states have adopted the *Daubert* standard in recent years and a current list of those will be presented.

This study will present useful tools for potential witnesses to preclude a challenge, including material in Discovery and Inspection Rule 16 that requires copies of written reports and a written summary of any testimony that the government or the defendant intends to present under Federal Evidence Rules 702, 703, or 705. Rule 26 of the Federal Rules of Civil Procedure, General Provisions Regarding Discovery, will also be explained and the differences between the two highlighted. Every witness must be familiar with these rules and other requirements in these rules such as the witness's qualifications and any visual aids that are intended to be used at trial. Too often, prosecutors and witnesses alike fail to provide this information in discovery. An example of an expanded Rule 16, which provides more-than-required discovery material for the opinions and the methodology used, will be offered. Often, the education of opposing counsel as to how the witness intends to address and explain admissibility factors can be enough to preclude challenges of this type. One of the most difficult tasks facing the examiner is to ensure that their counsel is not only educated on the history of these challenges, but also understands the importance of preparation and comprehensive written responses.

Questioned Documents, Admissibility, Rule 16 and Rule 26

Questioned Documents Section - 2015

J24 The American Dreyfus Affair: Parallels Between the Alfred Dreyfus and the Leo Frank Matters in America

Arthur T. Anthony, BS, Forensic Document Examiner, PO Box 620420, Atlanta, GA 30362*

After attending this presentation, attendees will learn about the historical aspects of a notorious murder case that took place in Atlanta, GA, in 1913 and the involvement of questioned documents.

This presentation will impact the forensic science community by discussing how forensic science and the judicial system has evolved over the past 100 years.

In 1913, Mary Phagan, a teenage worker at the National Pencil Factory in Atlanta, GA, was found murdered in the basement of the factory. A handwritten note, in two pieces, was left at the murder scene and was the initial focal point of the investigation. This discussion will highlight the ensuing investigation by the Atlanta Police Department, the Pinkerton Detective Agency, and the defense team for Leo Frank, the factory superintendent who was ultimately charged with Phagan's murder.

Leo Frank, of Jewish descent, was born in Texas but, as a young man, moved to New York City with his family. He ultimately graduated from Cornell University with a degree in Mechanical Engineering. His uncle and two investors owned the National Pencil Factory in Atlanta, GA, and needed someone to take over its daily operation. They convinced Frank to travel to Germany to learn the pencil manufacturing process before taking charge of the factory. He spent approximately a year in Germany learning the business and, after returning to the United States, took over supervision of the Atlanta factory. Frank became a prominent member of the Atlanta Jewish community, at that time the largest in the American southeast.

Leo Frank ultimately became the focus in the murder investigation of Mary Phagan. He was tried and convicted of Phagan's murder and sentenced to death. The governor of Georgia commuted his sentence to life in prison hoping that Frank would be exonerated. Not satisfied with this, a vigilante mob dragged Leo Frank from the prison and took him to a remote area where he was hung. Some news articles of the time termed this tragedy as the American Dreyfus Affair. The parallels are similar as to the anti-Semitic aspects against both the principals, Alfred Dreyfus and Leo Frank, and their hatred by the public.

Questioned Documents, Murder, Anti-Semitism

Questioned Documents Section - 2015

J25 Standardization of Conclusions: Meeting Current Needs

Thomas W. Vastrick, BS, 522 S Hunt Club Boulevard, Ste 217, Apopka, FL 32803*

After attending this presentation, attendees will have a better understanding of how current activities may require modification to standards.

This presentation will impact the forensic science community by bringing attention to the need to address the schism between scientific language and legalese. In addition, this presentation will propose standard modifications in keeping with the National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward*.

Forensic document examination has utilized standardization of conclusions for many years now. Many would harken back to a popular paper authored by Thomas McAlexander, Jan Beck, and Ron Dick that provided the outline that was adopted by **Scientific Working Group for Forensic Document Examination (SWGDOC)** and eventually became the American Society for Testing and Materials (ASTM) Standard E-1658 which was not only referenced but quoted verbatim in the NAS Report. Subsequent to the aforementioned NAS Report, there have been no significant changes to the standardization of conclusions; this does not mean that we necessarily have to change anything. However, this presentation brings one examiner's thoughts for limited modification to the table for discussion and debate. Prompters to these ideas have been the NAS Report, discussions with other document examiners, and suggestions from the legal profession.

The NAS Report specifically states that forensic examinations should culminate in conclusions. There have been other presentations that have suggested a wholesale termination of providing conclusions, but this is not in line with the recommendations of the NAS Report and contrary to the path that forensic science is taking. The report develops further that reports should, "describe, at a minimum, methods and materials, procedures, results, and conclusions, and they should identify, as appropriate, the sources of uncertainty in the procedures and conclusions along with estimates of their scale (to indicate the level of confidence in the results)."

Examiners often come in contact with questions concerning the relationship between scientific terminology and legal terminology. The most common situation involves the question, "Is your conclusion within a reasonable degree of scientific certainty?" Many examiners shudder at this question, primarily because the legal profession appears to be unable to provide a standardized definition for that term. Another common question is, "How does the confidence level of our conclusions coincide with the legal levels of proof requirement?"

Document examiners have expressed certain concerns with the current status of standardized terms to include some of the language used and that the standard reflects an inaccurate implication that the association side of the conclusion scale and the disassociation side of the conclusion scale are mirror images. It is widely accepted within the practice of forensic document examination that eliminations are inherently more difficult than identification (in general). As such, the level of evidence is often much stronger for elimination than its counterpart in order to reach a level of confidence required to use comparable vocabulary in the conclusion statement.

This presentation addresses these issues and proposes modifications to the current standard that directly address all of these concerns. This presentation is one examiner's opinion and should be considered as such — hopefully initiating conversation and further debate leading to action.

The structure of forensic science standardization appears to be headed toward a major shift. However, as is commonly known by questioned document examiners, all known movement of such monumental proportions are often slow and should be considering the seriousness of the task. As such, it remains with each discipline within the forensic sciences to maintain the best possible standards. Examiners need not wait on anyone. If one profession does not provide a standard for a term or phrase, why can't the subject-matter expert provide a definition that can be used as a standard by those within our profession?

Conclusions, Standards, Handwriting

Questioned Documents Section - 2015

J26 A New-Dominant Hand: Training the Non-Dominant Hand to Perform the Complex Task of Handwriting

Brenda N. Lanners, BS, San Diego County Sheriff's Regional Crime Lab, 5255 Mount Etna Drive, San Diego, CA 92117*

After attending this presentation, attendees will have an understanding of the problems and challenges encountered when writing with the non-dominant hand and will be aware of possible differences and improvements that can be expected in non-dominant-handwriting over time.

This presentation will impact the forensic science community by bringing awareness to a growing source of handwriting that may appear to be disguised or distorted, by assisting Forensic Document Examiners (FDEs) in understanding the process involved when training the new-dominant hand, and by highlighting certain features and characteristics that might be observed in the handwriting produced by the new-dominant hand.

Use of the non-dominant hand is a method sometimes utilized to disguise one's handwriting. FDEs are always mindful of possible disguise in questioned and known handwriting when performing examinations, but it should be remembered that use of the non-dominant hand is not always used as a means of disguise. Sometimes, it is forced on a writer due to amputation, illness, immobility, or other factors. Consider for a moment, veterans of the Iraq and Afghanistan wars. As of December 31, 2013, there have been 1,558 major limb amputations performed on United States soldiers.¹ United States soldiers remain in combat in parts of the world today, so these numbers are likely to increase.

So, it was with our soldiers and wounded veterans in mind that this study began. With guidance from a book called *Handwriting for Heroes: Learn to Write with Your Non-Dominant Hand in Six Weeks*, this study documents a six-week process of training a writer to use the non-dominant hand to perform the complex task of writing.² The project consisted of 12 daily writing assignments, such as repetition of letter combinations, tracing cursive writing outlines, shading in objects with a pencil, and copying sentences. There was also a daily "homework" assignment meant to increase dexterity and coordination. Specific problems and challenges encountered during the exercises were documented. Differences between the dominant-hand writing and non-dominant-hand writing were seen in: slant, letter designs, retracings, beginning strokes, connecting strokes, speed, and fluency. Changes to the handwriting, which improved noticeably over the six weeks, were also documented.

Those who have lost the use of their dominant hand due to injury, illness, or amputation have no choice but to transform their non-dominant hand into their new-dominant hand. If faced with samples of their writing, it must be understood that they are not necessarily attempting to disguise their writing, but perhaps just trying to survive and thrive. This exercise is meant to bring awareness to a growing source of handwriting that may appear to be disguised or distorted, to assist FDEs in understanding the process involved when training the new-dominant hand, and to highlight certain features and characteristics that might be observed in the handwriting produced by the new-dominant hand.

J27 The Reliability of Hand Printing Identification by the Forensic Document Examiner

Linda L. Mitchell, BS*, 243 S Escondido Boulevard, #304, Escondido, CA 92025-4116; and Mara L. Merlino, PhD*, 1066 Tamworth Lane, Frankfort, KY 40601

After attending this presentation, attendees will be aware of the preliminary results of the most recent study involving the ability of the Forensic Document Examiner (FDE) to properly identify the authors of block printing. They will also have reviewed the most current *Daubert* rulings on this aspect of handwriting analysis.

This presentation will impact the forensic science community by explaining how the results of this study will directly affect future *Daubert* challenges by providing blind study data that could potentially support the premise that current protocols for forensic handwriting analysis also apply to hand printing, specifically block printing.

On October 8, 2013, the 7th United States Federal Court for the Western District of Wisconsin conducted a *Daubert* hearing to determine whether testimony by an FDE regarding the identification of hand printing “rests on a reliable foundation.”¹ The court ruled that the theories of handwriting analysis have not been adequately tested and found reliable when applied to hand printing. In this instance, Bolsover’s testimony was excluded.

Alternatively, in May of 2014, there was a similar request for a *Daubert* hearing in the 15th Judicial Circuit Court in Palm Beach, FL, regarding the reliability of testimony of the identification of hand printing.² The court ruled that *Daubert* requisites had been met by FDEs William Flynn and Grant Sperry. Testimony of this kind was supported by the 2002 Kam/Lin study wherein it was indicated that FDEs perform better than laypersons in the identification of both cursive and hand printing.³

It has been widely noted in the media and within the forensic community that hand printing, specifically block letters, has become more commonly used in everyday writing. It is very frequently seen in forms, addresses, and work-related communications as well. Because of these factors, it has become increasingly important to verify for the purposes of *Daubert* that forensic examination of hand printed documents by qualified FDEs is reliable. This study was undertaken in partial response to the previously cited lack of supporting research in the area of hand printing. It is the purpose of this research to determine the FDE’s reliability in identifying block letter hand printing (ALL CAPITALS) using the same methods and protocols as cursive. The virtual absence of lower-case letters in this study is expected to reduce the amount of potential variation and individualizing characteristics present for identification purposes. It likewise mirrors block printing common to FDE casework.

The materials within the study packets were intended to reflect evidence and procedures similar to normal bench work in a condensed form. Twenty-five questioned writings were offered in individual “case packets.” Each was associated with sample writing of three potential “suspects.” Participants were asked to opine (on a nine-point scale) whether or not each suspect was the writer.

The “testing” portion of this study was concluded in October 2014 and the compiled data was analyzed under the auspices of Dr. Mara Merlino. The preliminary results will be presented along with potential interpretations of the analyzed data sets.

J28 Some Reasons for Qualified Conclusions

Ronald N. Morris, BS*, 307 Springhill Circle, PO Box 905, Bedford, VA 24523

The goal of this presentation is to discuss some of the reasons why a Forensic Document Examiner (FDE) is not always able to reach or express an unqualified conclusion after conducting an examination and comparison between questioned and known writings.

This presentation will impact the forensic science community by providing a better understanding of the reasons for and rationale behind the necessity to express qualified conclusions in those cases where the evidence in the examined writing is less than conclusive. This discussion is very important because currently some believe that in every science it is possible to always reach an unqualified conclusion. This position is blatantly absurd.

The examination and comparison of handwriting and hand printing is a reliable means of identifying individuals based on their writing habits. It is reliable when the FDE properly, accurately, and conservatively applies the established principles of handwriting and hand printing identification that have been proven true and correct over many years. These principles are well documented in numerous texts and technical papers written by qualified, competent, and ethical FDEs around the world.

Reaching any conclusion concerning authorship of writing must be supported by the combined significance of the evidence in the examined writings. In many cases, the evidence does not support an unqualified conclusion and when it does not, the FDEs must determine what degree of belief they have concerning authorship. This presentation addresses some of the reasons for qualified conclusions and the language used to express them.

There are numerous technical reasons for qualified conclusions. Several examples of why it is not always possible to either identify or eliminate a writer will be discussed in the presentation.

Some of the reasons to be presented and discussed are: (1) the writing is insufficient in quantity or quality and therefore has marginal value for comparison purposes, either questioned or known, or both; (2) limited writing, that is the writing may consist of a few general letterforms or marks; (3) sufficient individuality in the writing; (4) unnatural or disguised writing; (5) simulation or tracing; (6) patching and retouching of letters and words that is not explainable or an irreconcilable difference between the questioned and known writing; (7) completely different styles of writing that may have a limited amount of similar characteristics; (8) writing that is not contemporaneous; (9) the presence of transitory and/or accidental features not present in both questioned and known samples; and, (10) the examination of photocopies, faxes, and digitally produced writing.

The principle that is presented is that identification or elimination of a writer is based on the cumulative effect of all the available observable evidence in the examined writing. It should not be based on the presence or absence of any single characteristic, quality, or feature in common or different in the writing. If the cumulative evidence is not sufficient to reach the conclusion that there absolutely was or was not another writer of the questioned writing, then an identification or elimination conclusion is justified.

This same principle applies when there is insufficient evidence to reach an unqualified conclusion. The cumulative evidence, while not sufficient for an identification or elimination, must be sufficient to express a qualified conclusion. The level of certainty expressed by the language used must be accurate in expressing the degree of belief the FDE has concerning the results of his/her examination and comparison.

Handwriting, Qualified, Conclusions

J29 Forensic Document Examiner (FDE) Testimony Related to Quality Processes Denied — What a Florida Jury Did Not Hear and More (or Less)

Grant R. Sperry, BS, Forensic Doc Exam Services, 7859 Cross Pike Drive, Germantown, TN 38138-8117*

After attending this presentation, attendees will have been provided information on how certain courts may apply adverse rulings to the various quality processes and methodologies employed by forensic document examiners.

This presentation will impact the forensic science community by providing insight on the judicial demands of the forensic science disciplines and the resulting counterintuitive decisions by the judiciary when those demands are met.

This presentation will discuss the facts and circumstances surrounding forensic document examinations and three subsequent trials of an individual accused of murdering a young assistant manager at a popular chicken restaurant in West Palm Beach, FL, more than 15 years ago.

The specifics of the lengthy and controversial investigation and multiple trials will shed light and promote discussions on forensic document examination processes, testimony, extremely controversial rulings, un rebutted “expert critic” testimony, and the tainting of testimony by association.

In 1999, a young 18-year-old assistant manager at a West Palm Beach fast food restaurant was bound and shot execution-style while closing the restaurant. Almost five years later, the questioned handwriting allegedly written by one of the perpetrators while at the scene and purported known writings of numerous individuals were submitted to the laboratory by investigators with the West Palm Beach Police Department and later from the State Attorney General’s office. Two examiners from different laboratories ultimately identified the same individual as the person responsible for the questioned writing. In each instance, the conclusions reached by the primary examiners were reviewed by another FDE as part of each laboratory’s quality assurance process.

The first trial resulted in a mistrial (eleven to one, guilty). The second trial resulted in a guilty verdict. The Florida Court of Appeals reversed the conviction on the grounds that the FDEs testifying about their peer review process were, in effect, bolstering their testimony. The court ruled the trial judge was in error by allowing each FDE to testify to their quality review process, without providing the opportunity to the defense to cross-examine the FDEs conducting the quality review. Of course, there were depositions of the FDE conducted prior to trial and the defense was well aware of the processes employed with respect to quality review and verification at both FDE laboratories.

This presentation addresses the forensic document examinations, the process methodology employed by two recognized forensic laboratories, testimony by two FDEs at multiple trials, and the controversial rulings by the court on several issues, including the court’s refusal to allow testimony by more than one examiner, the court’s decision to forbid testimony by the FDEs who provided the peer review and verification, and the spill-over impact or tainting of the case based on issues related to problematic investigative techniques.

At the third trial, the defendant was acquitted. In that trial, not only was the FDE forbidden to provide the jury with information on the quality processes employed, but the court ruled the FDE who conducted the quality/peer review would not testify because the testimony would amount to “bolstering.” So, this begs the question...just exactly how is the jury to assess the reliability of our quality processes if we are not allowed to testify to them and/or if other FDEs involved in the process are precluded from testifying as to their role in the process? As a result of another questionable ruling from the bench, a rebuttal witness to the testimony of a pervasive “expert critic” was not allowed to testify.

There are certainly anomalies within the circumstances of this case and rulings by the court which may never appear again as they did in this case. However, the rulings in this case are difficult to understand given the past criticisms of the judiciary and other critics. The ever-critical judicial system has demanded of the forensic science profession methodologies and processes which are well-grounded in science and quality. Yet, in this case, the jury was forbidden to hear about the methodology and quality processes the forensic document examination community has been criticized for failing to employ in years past. As forensic document examiners, this is indeed cause for concern.

Quality Process, Methodology, Bolstering

Questioned Documents Section - 2015

J30 The Forensic Document Examiner Testimony List

Ellen M. Schuetzner, BA, 6348 N Milwaukee Avenue, #161, Chicago, IL 60646-3728*

The goal of this presentation is to make attendees aware of a testimony list that can be used in court challenges to the profession. This list can be used by examiners in criminal and civil cases and provides information about the types of examinations and opinions that are being offered in courts across the United States.

This presentation will impact the forensic science community by making forensic document examiners aware that a testimony list is available so they can be better prepared for a court challenge. A forensic document examiner can also learn how and why he/she should maintain his/her own list and contribute to this continuing list.

Since the *Daubert v. Merrell Dow Pharmaceuticals, Inc.* decision and its requirements for testimony, there were many challenges to the testimony of forensic document examiners. To address some of the court challenges to the testimony of forensic document examiners, a list of the testimony by these practitioners was started and continues to be maintained. This list includes criminal and civil cases, municipal, county, state, and federal cases in the United States and some of its overseas courts. Some administrative and other governmental hearings have been included. The list includes only testimony in which judges have allowed the forensic document examiner to testify to his/her opinion in court.

The list was started in the year 2000 in response to some of the *Daubert* challenges that forensic document examiners faced. It is a collection of testimony by qualified forensic document examiners since the advent of the *Daubert* ruling in 1993. It includes the name of the case, the date of testimony or date of decision in the case, the location of the trial, the type of court, and the type of opinion(s) and examination(s) that were testified to. These examinations and opinions are only those that are related to forensic document examination. Those who have contributed are examiners who were trained by traditional methods such as those described in the American Society for Testing and Materials (ASTM) *Standard Guide for the Minimum Training Requirements for Forensic Document Examiners*.

Forensic document examiners from all over the United States have contributed to this testimony list. Some examiners have submitted their list after many years of testimony and some contribute after each testimony. The list has entries from all fifty states and other judicial jurisdictions. Since its inception, the list has been used in *Daubert* challenges and it has been made available when *Daubert* challenges are threatened. In one recent case, the judge commented that the evidence demonstrated that the testimony of forensic document examiners was regularly admitted in courts throughout the United States.

This presentation will address the contents of the testimony list, including a breakdown of how the list is formulated, some of the entries, the statistics of some of the entries, and the use of the list in some court cases. One of the purposes of this presentation is to encourage forensic document examiners to continue their testimony lists to the ongoing effort to keep this testimony list current and usable for future court cases.

Forensic Document Examination, Testimony List, Court Challenge

Questioned Documents Section - 2015

J31 The Scientific Working Group for Forensic Document Examination (SWGDOC) and the Organization of Scientific Area Committees (OSAC) Process

Ted M. Burkes, BS, FBI Laboratory, 2501 Investigation Parkway, Rm 2174, Quantico, VA 22135; and F.L. Jim Lee, Jr., MS*, PO Box 207, Eden, UT 84310*

The goal of this presentation is to educate forensic document examiners on the future of standards development.

This presentation will impact the forensic science community by educating it on the future of standards development. Courts of law are relying more on the use of standards in an expert's examinations. Lack of this knowledge may impact a practitioner's allowance to testify as an expert witness.

SWGDOC has been in existence, under different names, since 1997. With the genesis of OSAC by the National Institute of Standards and Technology (NIST), the Scientific Working Groups (SWGs) will be both replaced and combined. There will be five Scientific Area Committees (SAC), each with several subcommittees representing what have up to now been the SWGs. The subcommittee for Questioned Documents (QD) will be under the Physics/Pattern SAC. At the time of this abstract, the members of the Physics/Pattern SAC (other than the chair) and the QD subcommittee have not been publicized.

This study will present an up-to-date analysis of the OSAC process and the conversion from the SWGDOC business model to the OSAC business model. This presentation will include the members of the QD subcommittee and their backgrounds, as well as the members of the Physics/Pattern SAC and their backgrounds. The membership of each subcommittee is currently planned for a maximum of 20 voting members, broken down with a distribution goal as follows: 70% (14) practitioner (20% (four) federal, 30% (six) state and local, 20% (four) civil or other; 20% (four) researchers (including statisticians, epidemiologists, etc.); and, 10% (one) Research and Development (R&D) technology partners and providers. There is also a plan to allow up to five invited guests per meeting. The plan is for the subcommittees to meet in person once per year, with virtual meetings occurring more often. It is the understanding of the presenters that membership will be for a specific period of time (perhaps three years) and there will possibly be term limits on the number of times an individual can hold consecutive memberships. As a point of reference, SWGDOC currently has 38 members, all practitioners, with a balance of federal, state and local, and private practitioners. SWGDOC also has two international members. It is unknown at this time if there will be any international members involved in the OSAC process.

The OSAC process for drafting, vetting, and publishing standards, guidelines, and best practices will also be presented. This process, depending on the type of document being considered, also includes reviews for Human Factors, Legal Analysis, and Quality Infrastructure. The Forensic Science Standards Board will give the final blessing on documents that are intended to be labeled as "standards" under the OSAC process. Those that will be labeled as guidelines and best practices need only be approved at the Physics/Pattern SAC level.

SWGDOC, OSAC, Questioned Documents

K1 A Reduced Workflow Solution for the Analysis of Gamma-Hydroxybutyrate (GHB) in Human Hair Samples Via an Automated Bead Mill as a Precursor to High Resolution-Gas Chromatography/Time-of-Flight (GC/TOF) and 2D Gas Chromatography/Time-of-Flight (GCxGC/TOF)

Brad Nolt, MS*, Biotage, 10430 Harris Oaks Boulevard, Ste C, Charlotte, NC 28269; *Tom Enzweiler, BS*, Biotage, 10430 Harris Oaks Boulevard, Charlotte, NC 28269; *Rhys Jones, PhD*, Biotage GB Limited, Dyffryn Business Park, Ystrad Mynach, Cardiff CF82 7TS, UNITED KINGDOM; *Lee Williams, PhD*, Biotage GB Limited, Dyffryn Business Park, Ystrad Mynach, Cardiff CF82 7TS, UNITED KINGDOM; and *Karen S. Scott, PhD*, Arcadia University, 450 S Easton Road, Glenside, PA 19038

After attending this presentation, attendees will be able to describe the usefulness of improved automated instrumentation for the determination of GHB in hair. Silylation of GHB is the most common derivatization technique employed with GHB for the analysis of forensic samples. This creates a challenge when testing hair samples due to interference from other endogenous compounds. One approach to cleaning up the samples is the use of mass spectrometric deconvolution software and multidimensional GC. In addition, it is critical to extract as much of a drug from the hair matrix as possible so this study has investigated the use of a Biotage® Bead Ruptor 24 to enhance the recovery of GHB from hair.

This presentation will impact the forensic science community by increasing awareness of alternative instrumental techniques that can be used to optimize the determination of silylated GHB in hair.

Techniques to interrogate hair samples have proven valuable in detecting human host exposure to drugs of abuse over a long sampling window. The hair matrix is challenging to work with and a number of methods have been reported. This investigation details the feasibility of incorporating an automated bead mill to homogenize the matrix and disrupt non-selective analyte binding on a molecular level by destroying the matrix on a macro level. It was determined that the bead mill was effective in improving the efficiency of the subsequent digestion. Proof of concept was determined using adult human head hair samples (n=5) which were prepared in duplicate using the laboratory's standard preparation procedure (cutting the hair into 1mm-2mm segments using scissors) versus automation in the bead mill at the Center for Forensic Science Research and Education in Willow Grove, PA, using a Biotage® Bead Ruptor 24. The homogenized samples were incubated overnight in methanol at 40°C, filtered, and evaporated to dryness. The sample tubes were sent to Leco's application laboratory in Saint Joseph, MI, for derivatization and GC/TOF analysis, followed by post-acquisition deconvolution software. A GCxGC approach was employed to mitigate a co-eluting peak tentatively identified by Pharmacy Benefit Manager (PBM) software as Tetramethylsilane (TMS) -urea. The GCxGC method was successful for the selective analysis of GHB in hair. Preliminary data suggests alternatives to GCxGC may be found in Solid Phase Extraction (SPE) techniques prior to single stage GC/MS. Additional samples from a range of individuals (age and sex) were similarly prepared and tested via the optimized GCxGC/TOF method. This method was found to give better specificity and sensitivity than GC/MS and is effective in separating GHB-2TMS from endogenous interferences.

GHB, Bead Ruptor, GCxGC/TOF

K2 A Novel Extraction Methodology for the Analysis of Lorazepam and Oxazepam Glucuronide Hydrolysis in Meconium

Kaylee R. McDonald, BS*, 631 Sumter Street, Columbia, SC 29208; William E. Brewer, PhD, University of South Carolina, Dept of Chem & Biochem, 631 Sumter Street, Columbia, SC 29208; and Stephen L. Morgan, PhD, University of South Carolina, Dept of Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208

The goal of this presentation is to present research studies establishing a novel analytical approach to the analysis of benzodiazepines in meconium using an enzymatic hydrolysis step *in situ*, followed by weak anion exchange clean-up in a disposable pipette, prior to analysis by Liquid Chromatography/Mass Spectrometry (LC/MS). Attendees will learn how the proposed methodology reduces biological matrix effects and minimizes sample preparation time.

This presentation will impact the forensic science community by illustrating how the proposed analytical methodology provides practical advantages over existing methods in terms of rapid sample clean-up and the removal of biological matrix effects that could potentially interfere with the determination of benzodiazepines by LC/MS. This method enables routine rapid monitoring of meconium for cases of suspected drug abuse.

Benzodiazepines are a schedule IV class of psychotropic drugs commonly used for their depressant properties.¹ Monitoring benzodiazepines in meconium is critical both for monitoring abuse by pregnant women and to identify potential health risks for newborns. Benzodiazepines are thought to possibly cause oral clefts.² Although analysis of urine can be simple and fast, benzodiazepine metabolites persist in urine only for a few days after use and drug exposure may be underestimated. Meconium is a valuable toxicological matrix because it acts as a repository for xenobiotics including drugs of abuse from the 16th week of gestation until birth; however, the use of meconium as a biological matrix to monitor drug use by liquid chromatography/mass spectrometry is problematic because of the potential for large matrix effects.^{1,3} Reducing matrix effects requires extracting target analytes from the endogenous biological interferences, a task that is often time consuming and labor intensive. The objective of the present research is to minimize both meconium matrix effects and sample preparation time by a hydrolysis step *in situ*, followed by weak anion exchange disposable pipette extraction tips for sample clean-up, prior to analysis of benzodiazepines by liquid chromatography/mass spectrometry.

An aliquot of 250 μ L of water was added to 25mg of blank standards of meconium in an Eppendorf tube. The mixture was vortexed until the meconium became homogeneously distributed/dissolved in the water. A solution consisting of 75mL of pH 7.5 potassium phosphate buffer, 50mL of a β -glucuronidase enzyme, and 10mL of 500ppb internal standard in water, was added. This mixture was then incubated for one hour at 55 $^{\circ}$ C. A 600mL aliquot of acetonitrile was added to the mixture to precipitate proteins. This mixture was vortexed and centrifuged. The supernatant was removed and placed into a clean sample vial (~950ul solution). The solution was aspirated into a WAX-S tip (20mg 55-65um resin/40mg salt) twice. This step separates the acetonitrile and water layers and facilitates transfer of the analytes into the cleaner acetonitrile supernatant. The top acetonitrile layer (~500-600ul) was then transferred to a vial suitable for solvent evaporation. This step separates the acetonitrile and water layers and facilitates removal of the analytes in the acetonitrile supernatant. After evaporation in a fresh vial, the residue was reconstituted in 100mL of 10:90 methanol:water.

All analyses were performed using a triple quadrupole system with an Agilent[®] 1100 HPLC with a C-18 column (3.0 x 50mm, 2.7 μ m). Sample injections of 20 μ L were made using an injection valve incorporated on an autosampler. The mobile phase used 0.1% formic acid in water (A) and 0.1% formic acid in acetonitrile (B). The initial gradient was 70% A for 0.25min, which ramped to 5% A at 2min. The gradient remained at 5% A for 1min, then back to 70% A for a total run time of 6.5min. The eluent was diverted to waste during the intervals of 0-0.5min and 5-6.5min after injection. The column flow rate was 0.4mL/min. The electrospray voltage was 4,000V and the gas pressure was 60psi.

Initial success of hydrolysis was illustrated through analysis of neat meconium samples spiked with lorazepam and oxazepam glucuronides. Post-hydrolysis, a decrease of the glucuronides and concurrent increase in the parent compounds demonstrated that the method was viable. To test the validity of this method further, a blind study was performed with a collaborative laboratory including 35 meconium patient samples tested for ten benzodiazepines and/or metabolites. The blind study resulted in a correlation of approximately 92%. In conclusion, the combination of fast hydrolysis, coupled with a simple clean-up scheme, offers an effective analytical approach for the analysis of benzodiazepines in meconium.

K3 Analysis of Promethazine, Chlorpromazine, and Selected Metabolites in Decomposed Skeletal Tissues by Microwave-Assisted Extraction/Microplate Solid Phase Extraction/Ultra High-Performance Liquid Chromatography (MAE/MPSPE/UHPLC)

Courtney A. Campbell, BS, Laurentian University, 935 Ramsey Lake Road, Sudbury, ON P3E 2C6, CANADA; James Watterson, PhD, Laurentian University, 935 Ramsey Lake Road, Sudbury, ON P3E 2C6, CANADA; and Caroline C. Betit, MSc, 935 Ramsey Lake Road, Sudbury, ON P3E 2C6, CANADA*

After attending this presentation, attendees will understand how to develop a microwave-assisted extraction methodology using bone tissue. An example of this methodology's practical application using vertebral bone will be presented.

This presentation will impact the forensic science community by adding to the body of data illustrating the utility of skeletal tissues as a matrix for toxicological analysis and by demonstrating an efficient method for preparation of skeletal tissue samples.

The purpose of this study was to develop and validate a Microwave Assisted Extraction (MAE) followed by a Microplate Solid Phase Extraction (MPSPE) method for the detection and semi-quantitation of Promethazine (PMZ), Chlorpromazine (CPZ), and selected metabolites (promethazine sulphoxide, desmethylpromethazine, chlorpromazine sulphoxide, and desmethylchlorpromazine) in the skeletal remains of rats using Ultra High Performance Liquid Chromatography (UHPLC).

Male Wistar rats (n=10) received either a dose of PMZ (50mg/kg, i.p.) or CPZ (50mg/kg, i.p.). Five rats acted as drug-free controls. The rats were euthanized by CO₂ asphyxiation 20min after exposure and placed outdoors to decompose to skeleton. Vertebral bone was recovered and washed with 3mL Phosphate Buffer (PBS: 0.1M; pH6), 3mL methanol, and 3mL acetone and air-dried. Bones were pulverized and samples underwent MAE in 5mL of methanol at 80°C in a MARS™ 6 microwave oven for a total of 60min, with extraction solvent recovered and replaced with fresh solvent at 15min and 30min. All solvent extracts were recovered, evaporated to dryness, and reconstituted in 1mL of Phosphate Buffer Saline (PBS). Promazine was added as an internal standard (500ng) and extracts then underwent protein precipitation by adding 1mL of PBS along with 3mL of acetonitrile-methanol (1:1) followed by storage at -20°C for 24h. The samples were centrifuged and the supernatant was collected and evaporated to 1mL. PBS (2mL) was utilized to dilute the samples which were then acidified with 100µl of acetic acid. All samples were subjected to SPE using XCEL I (130mg) 48 microwell plates. Wells were conditioned by sequential addition of 3mL methanol, water, and PBS. Samples were loaded by gravity. Wells were washed with PBS (3mL) and 0.1M acetic acid (3mL) and dried for 5min under vacuum (10 in Hg). Wells were washed with methanol (3mL) and dried for 10min (10 in Hg). Analytes were eluted using 3% NH₄OH in 20:80 isopropanol:dichloromethane (3mL). Extracts were evaporated to dryness and reconstituted in 500µL of mobile phase A (0.1 % formic acid in 90:10 water:acetonitrile). Samples were centrifuged for 10min and then 15µl of sample was injected into the UPHLC with Photodiode Array Detection (PDA). The column used was a Raptor™ biphenyl column (150mm x 2.1mm, 1.7µm) with a column temperature set to 50°C. The mobile phase gradient began with 95:5 A:B (B: 0.1%formic acid in 90:10 acetonitrile:water) held for 1min, then increased to 70:30 A:B over 4min, held for 1min, then increased to 20:80 A:B over 3min, and reversion back to 95:5 A:B which was held for 1min, for a total run time of 10min at a constant flow rate of 0.400mL/min. Quantitative measurements were made using the response ratio measured at 240nm for the sulphoxide metabolites and 250nm for the remaining analytes.

Method validation involved preparation of standard analyte samples in drug-free Bone Tissue Extract (BTE). The response ratio was linear from 10ng/mL to 5,000ng/mL ($R^2=0.990-0.999$). The precision was <25% (n=3 on each of three different days). The limit of detection was approximately 10ng/mL for each analyte, and the limit of quantification for the method was approximately 25ng/mL for each analyte. The majority of analytes were recovered after 30min extraction interval. Analytes were stable under the microwave extraction for at least 60min.

Promethazine, Chlorpromazine, Bone

K4 Detection of Trace Buprenorphine and Norbuprenorphine in Human Hair Using Enzyme-Linked Immuno-Sorbent Assay (ELISA)

*Irene Shu**, 1700 S Mt Prospect Road, Des Plaines, IL 60018; *Valencia Sagnia, BS*, 1700 S Mount Prospect Road, Des Plaines, IL 60018; and *Joseph Jones, MS*, 1700 S Mount Prospect Road, Des Plaines, IL 60018

After attending this presentation, attendees will be able to develop, validate, and implement an ELISA method in their forensic toxicology laboratories for detecting buprenorphine and its metabolite, norbuprenorphine, in human hair.

This presentation will impact the forensic science community by introducing a sensitive, robust, and short turn-around-time method to detect both the parent drug and the metabolite to support surveillance of compliance with opioid dependence treatments.

Buprenorphine (BUP) is a partial mu opioid agonist with kappa opioid antagonist property that has been used as a substitution drug for opioid dependence treatment; however, the drug has potential for abuse and is more easily obtained than other substitution drugs such as methadone. A few studies have suggested that hair analysis of BUP and norbuprenorphine (norBUP), the major N-dealkylated metabolite, can complement urine drug analysis to monitor the drug intake in a detection window of up to three months. Combined BUP and norBUP were reported to accumulate to more than 20pg/mg in hair at a dose as low as 0.2mg/week maintained for two to three months.

Currently at this study's laboratory, only a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method has been implemented to quantitate both BUP and norBUP in human hair with a Lower Limit Of Quantitation (LLOQ) of 8pg/mg for each analyte. Only ~30% of the hair samples in the laboratory reported out with quantitated results had BUP/norBUP ratio greater than 1.0 (BUP 8 — 1,517pg/mg, norBUP none-detectable — 1,295pg/mg), and the rest had norBUP as the predominant analyte, including those in which only norBUP was quantitated (BUP none-detectable — 775pg/mg, norBUP 19 — 2,192pg/mg).

An ELISA method was sought to be utilized as the initial detection method, which ideally should detect both the parent drug and its metabolite at the desired analytical sensitivity.

An ELISA kit targeting BUP was validated according to the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines. An approximate 20mg aliquot of 1.5-inch hair segment proximal to scalp was washed once with acetone, pulverized, and then sonicated with heat in 1.5mL methanol for two hours. The methanol mixture was centrifuged and 1.0mL of the resulting supernatant was evaporated and reconstituted with the diluent provided by the ELISA kit. Laboratory-determined volume of the final reconstituted hair extract was then pipetted for ELISA development according to the manufacturer's package insert. The assay principle is heterogeneous-competitive ELISA, where the intensity of the developed color is inversely proportional to the sample drug concentration. The absorbance of each sample well was normalized to that of the negative controls (B/B0) within the same batch. The desired cut-off level was 20pg/mg of BUP in hair.

Controls at five concentrations (cut-off, $\pm 25\%$ and $\pm 50\%$ of cut-off) were prepared for analysis of precision and a control at 100pg/mg was included to determine extended assay linearity. Coefficients of variation for the measured B/B0 were 4.6%-11.4% within-run ($n=4$) and 7.6%-11.7% between-run (five runs, $n=20$). The B/B0 mean ± 2 Standard Deviations (SDs) for concentrations at $\pm 50\%$ of cut-off were well separated from the mean B/B0 at cut-off. Correlation coefficient R^2 of B/B0 versus concentrations (expressed in logarithm) was 0.9953, demonstrating satisfactory linearity. The mean B0 — $3.3 \times$ SDs determined limit of detection to be 6.3pg/mg. The ELISA did not present hook effect and carry-over at least at 2,000pg/mg. The assay did not show interference from common over-the-counter or prescription drugs at 25ng/mg.

The previously analyzed hair samples in-house for BUP and norBUP by LC/MS/MS were de-identified and randomly chosen based on their quantitated results for ELISA analysis. The hair samples were categorized into three groups: (1) High BUP group with >30 pg/mg of both BUP (32 — 1,517pg/mg) and norBUP (155 — $>2,000$ pg/mg) ($n=10$); (2) Borderline BUP group with non-detectable — 21.7pg/mg BUP and 27.3 — 123pg/mg norBUP ($n=8$); and, (3) Negative BUP group with non-detectable BUP and norBUP ($n=9$). All High BUP and seven Borderline hair samples were determined positive, and all Negative hair samples were determined negative by the ELISA method. One Borderline hair sample (BUP=17.9, norBUP=54.2pg/mg) was equivocal to cut-off controls. With this limited sampling size, the ELISA demonstrated to detect both parent drug and its metabolite, achieving $\geq 94.4\%$ sensitivity and 100% specificity.

Toxicology Section - 2015

To provide forensically defensible toxicology results, an initial detection of substances should be confirmed whenever possible by a second technique based on a different chemical principle. The ELISA developed and validated herein satisfies the laboratory's needs to be implemented as an appropriate initial test method to complement the currently used confirmatory LC/MS/MS method.

Buprenorphine, Hair Testing, ELISA

K5 The “I’s” Have It: A High-Performance Liquid Chromatography Tandem Mass Spectrometry Method for the Determination of 25I-NBOH, 25I-NBOMe, and 2C-I in Urine

Sara Dempsey, BS*, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284; Justin L. Poklis, BS, Virginia Commonwealth University, Dept of Pharmacology & Toxicology, 410 N 12th Street, Rm 746, PO Box 980613, Richmond, VA 23219-0613; Carl E. Wolf II, PhD, PO Box 980165, Richmond, VA 23298-0165; and Alphonse Poklis, PhD, Virginia Commonwealth University, Dept of Pathology-Toxicology Laboratory, Box 98-165 MCVH/VCU Station, Richmond, VA 23298-0165

After attending this presentation, attendees will understand how to analyze for the three 4-iodo-2,5-dimethoxy-phenethylamines designer hallucinogens.

This presentation will impact the forensic science community by offering a method for the identification and quantitation of three designer hallucinogens in human urine which may be used in clinical and forensic toxicology laboratories.

Introduction: In 2010, a novel class of designer hallucinogens, the N-methoxybenzyl-methoxyphenylethylamine (NBOMe) derivatives of Alexander Shulgin’s 2,5-dimethoxy-phenethylamines, became readily available on the internet. These derivatives are potent serotonin 2A (5-HT_{2A}) receptor agonists. Currently, NBOMe derivatives are sold as powders or on blotter paper with 25I-NBOMe (4-iodo-2,5-dimethoxy-N-(2-methoxybenzyl)-phenylethylamine) being the most commonly reported. Clinical presentations of severe NBOMe intoxication include tachycardia, agitation, hypertension, aggressive/violent behavior, hallucinations, and continuous agitation and seizures which can persist for as long as three days. In November of 2013, three designer phenethylamines, 25I-NBOMe, 25C-NBOMe, and 25B-NBOMe (the 4-chloro- and 4-bromo- 2,5-dimethoxy-N-(2-methoxybenzyl)-phenylethylamine), were temporarily declared Schedule I drugs. Recently, unscheduled NBOMe type derivatives have become available, with anecdotal evidence suggesting that 2-((4-iodo-2,5-dimethoxyphenyl)ethylamino)methylphenol (25I-NBOH) is the most prevalent. Shulgin’s designer hallucinogen, 2,5-Dimethoxy-4-iodophenethylamine (2C-I) is a precursor of both 25I-NBOMe and 25I-NBOH, and may be present in specimens as an impurity. Evidence also suggests 2C-I is a metabolite, formed by N-debenzylation, of both 25I-NBOMe and 25I-NBOH.

Objective: To develop a method for the detection and quantification of 25I-NBOMe, 25I-NBOH, and 2C-I in human urine as part of a dose response, disposition, metabolism, and behavioral studies concerning these designer hallucinogens.

Methods: An Ultra Performance Liquid Chromatography/Tandem Mass Spectrometry (UPLC/MS/MS) method was developed for the detection and quantification of 25I-NBOMe, 25I-NBOH, and 2C-I in human urine. Following the addition of the deuterated internal standard (25I-NBOMe-d₃), the hallucinogens were isolated by a previously published solid phase extraction method.¹ Chromatographic separation was performed on a Selectra® PFPP column, 10cm x 2.1mm, 3.0µm. The mobile phase consisted of A: water with 10mM ammonium formate, and B: methanol with 10mM ammonium formate. The following gradient was used: 0.0-3.0min starting at 60% B, with a linear gradient to 95% B, and then returning at 4.5min to 60% B. An injection volume of 5µL was used with a mobile phase flow rate of 0.4mL/min and a total run time of 4.5min. The following transition ions (m/z) were monitored for 25I-NBOMe: 428>121, 428>91, 428>272; 25I-NBOH: 414>107, 414>291, 414>308; 2C-I: 308>91, 308>276, 308>291; and, 25I-NBOMe-d₃: 431>124, 428>92, 428>275. The method was evaluated for absolute recovery, ion suppression, accuracy/bias, inter-day and intra-day precision, interferences, bench top stability, freeze/thaw, and post-preparative stability.

Results: Duplicate calibration curves were determined to be within 20% of the nominal value for each analyte. The linear regression correlation coefficients for each analyte’s calibration r² were 0.99 or greater. 25I-NBOMe and 25I-NBOH were linear from 10pg/mL to 500pg/mL, while 2C-I was linear from 50pg/mL to 500pg/mL. The Limit Of Detection (LOD) was administratively set at 10pg/mL for 25I-NBOMe, 25I-NBOH, and 2C-I. Assay performance was evaluated using a set of five quality-control specimens. Accuracy/bias of the assay was determined to be within +/-20% of the target value for each analyte in each quality control specimen. The CV for inter-day and intra-day precision samples did not exceed 15%, except for the Limit of Quantitation (LOQ) samples which did not exceed 20%. Two urine specimens were analyzed; one contained all three analytes, while the other specimen contained only 25I-NBOH.

Conclusion: This validated method was found to be robust and reliable for the detection and quantification of 25I-NBOMe, 25I-NBOH, and 2C-I in human urine.

Designer Drugs, UPLC/MS/MS, 25I-NBOMe

K6 Identification of Synthetic Cathinones From Electron Impact Mass Spectra

Rebecca J. Ponsini, MS*, 12443 Gardner Lane, Greensboro, MD 21639; and Sarah Kerrigan, PhD, Sam Houston State University, 1003 Bowers Boulevard, SHSU Box 2525, Huntsville, TX 77341

After attending this presentation, attendees will be able to describe characteristic fragmentation pathways for existing synthetic cathinones and predict new fragments for novel analogs as they arise.

This presentation will impact the forensic science community by highlighting the importance of mass spectral properties, the specificity of ion selection during analysis, and the practical limitations associated with some drugs within this class.

The popularity of synthetic cathinones and the diverse number of drugs within this relatively new class has increased considerably in recent years. Gas Chromatography/Mass Spectrometry (GC/MS) is still the most widely used technique in routine forensic toxicology investigations. Due to the proliferation of structural analogs and limited cross-reactivity toward the entire class of drugs, chromatographic-based screening is of great importance for the synthetic cathinones. Chromatographic separation of analytes can be readily achieved using multi-component mixtures; however, the Electron Impact (EI) mass spectral properties of some of the forensically important synthetic cathinones can present a challenge due to the limited number of diagnostic ions.

The characteristic fragmentation pathways synthetic cathinones are described and discussed for nineteen secondary and tertiary amines within this class. These include buphedrone, ethcathinone, methcathinone, pentedrone, 4-EMC, 4-MEC, flephedrone, mephedrone, methedrone, α -PVP, MPBP, naphyrone, pyrovalerone, butlyone, ethylone, methylone, pentylone, MDPBP, and MDPV. Although protonated molecular ions are readily observed using hyphenated Electrospray Ionization (ESI) techniques, parent ions are hard to obtain using EI/GC/MS. Molecular ions when they are present are odd, due to the "nitrogen rule." The mass spectra of synthetic cathinones are dominated by two characteristic cleavages to form iminium and acylium ions that are associated with the side chain and the core benzene ring (which is often substituted). The presence of the carbonyl bond on the α -carbon and the lone pair of electrons on the oxygen of the ketone moiety plays an important role in EI ionization. In addition to the rationalization of non-derivatized cathinones, acylation, silylation, and two-step reductive silylation and reductive acylation methods will also be presented and discussed in terms of their mass spectral properties. Although fragmentation is largely predictable, it presents some practical limitations in terms of the specificity of some diagnostic ions, necessitating careful attention to chromatographic separation and identification criteria.

Cathinones, Mass Spectra, Electron Impact

K7 Investigation of Unknown Designer Drugs and Metabolites in Urine Collected From Electronic Dance Music (EDM) Attendees

*Jillian K. Yeakel, MS**, 3864 Courtney Street, Ste 150, Bethlehem, PA 18017; *Amanda L.A. Mohr, MSFS*, Center for Forensic Science, Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; *John J. Kristofic, BS*, Armed Forces Medical Examiner System (AFMES), 115 Purple Heart Drive, Dover AFB, DE 19902; and *Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090

After attending this presentation, attendees will understand the process of structure elucidation and compound identification when unknown analytes are encountered using chromatographic and spectrometric techniques for the analysis of urine samples. This presentation may also give rise to the determination of novel compounds identified in the attendees of EDM festivals by allowing meeting attendees to contribute their input regarding similar peaks they may have encountered.

This presentation will impact the forensic science community by presenting the identification of several metabolites discovered in authentic urine samples that have not been thoroughly explored in the literature.

The designer drug market has continued to expand over the last several years with structural modifications continually being introduced in an attempt to skirt legal rulings. Blood, urine, and oral fluid samples were collected from volunteers attending an EDM festival in addition to asking the volunteers to answer questions regarding recent drug use, effects, and dosage. This group was targeted in an effort to attain authentic specimens from a population suspected to have a high likelihood of using designer drugs. The urine samples were analyzed via a battery of analytical methods in order to fully investigate the compounds present as well as the anticipation of detecting unknown analytes or metabolites. Results produced by the analysis on both Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Time-Of-Flight (LC/TOF) were key in the determination of unknown compounds. Samples were extracted using a solid phase extraction which targeted basic drugs to optimize the detection of designer stimulant and hallucinogen related compounds.

The GC/MS results were very promising with a quantity of designer drugs being detected including methylone, ethylone, butylone, dimethylone, 5-APB, fluoroamphetamine, and alpha-PVP. This presentation will describe the process to elucidate unknown peaks, several of which were minor metabolites of common compounds including cocaine, quetiapine, and dextromethorphan or were endogenous in nature. The most interesting unknown peaks were present in combination with alpha-PVP. The mass spectra of each of the two peaks displayed a prominent 126 ion, although the two peaks had separate retention times than all the other designer drugs present in the extensive in-house library. The samples were also analyzed on the LC/TOF and produced peaks with accurate masses and retention times that were unique to these unknown compounds as compared to the instrument database.

These two peaks of interest have yet to be identified and it is the goal of this presentation to allow the scientific community to comment and collaborate to aid in the identification of unpublished metabolites or novel compounds. The combination of structure prediction software, comparison of results from various analytical methods, and investigation of fragments using elemental composition serve as great tools in the elucidation of unknown compounds.

Metabolite Elucidation, Designer Drugs, LC-TOF

K8 Development of a Quantitation Method for Synthetic Cannabinoid Metabolites in Urine Using Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS)

*Craig Leopold, BS**, Arcadia University, 450 S Easton Road, Glenside, PA 19038; *Sherri L. Kacinko, PhD*, 3701 Welsh Road, Willow Grove, PA 19090; *Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; and *Karen S. Scott, PhD*, Arcadia University, 450 S Easton Road, Glenside, PA 19038

After attending this presentation, attendees will be able to perform a Liquid-Liquid Extraction (LLE) method followed by an LC/MS/MS method to extract, detect, and quantify synthetic cannabinoid metabolites of JWH-018, UR-144, AKB-48, AB-PINACA, ADB-PINACA, ADBICA, PB-22, 5F-PB-22, and BB-22 from urine.

This presentation will impact the forensic science community by demonstrating a validated method for the extraction and quantitation of metabolites of nine synthetic cannabinoids from urine samples. The parent drugs are currently scheduled by the Drug Enforcement Administration (DEA) as Schedule I compounds or have been recently identified as emerging cannabinoid agents being sold in synthetic cannabis blends. Development of an updated assay to detect and quantify the metabolites is important for forensic and toxicology laboratories for the assessment of prior consumption of the latest generation of synthetic cannabinoids.

Over the past few years, synthetic cannabinoids have become increasingly popular and prevalent in an effort by drug users to bypass current legislation and achieve a “legal” high. At the federal level in the United States, most are classified Schedule I substances by the DEA as they have a high potential for abuse and no medical purpose, so in an attempt to escape legal consequences, “manufacturers” produce compounds that are structurally different from currently scheduled drugs, but still give similar effects to achieve that high. JWH-018, UR-144, ADB-PINACA, AKB-48, PB-22, and 5F-PB-22 have been scheduled by the DEA while AB-PINACA, ADBICA, and BB-22 are currently not scheduled but have recently been identified as being components in synthetic cannabis blends in Japan and the United States. The structures of emerging synthetic cannabinoid compounds are believed to have similar properties to previously recognized compounds. As the number of compounds continues to increase, it is essential to develop a method that is versatile and can keep up with the rapidly emerging compounds as these newly emerged compounds may not register a positive result in common drug screening procedures.

An updated method was developed and validated to extract, identify, and quantify the N-pentanoic acid metabolites of JWH-018, UR-144, AKB-48, AB-PINACA, ADB-PINACA, and ADBICA; and the 3-carboxyindole metabolites of PB-22, 5F-PB-22, and BB-22 from urine, using LLE followed by LC/MS/MS. The metabolites were chosen based on the possibility of being active metabolites based on recent publications and also since there would be no detection issues as there could be with the various hydroxylated metabolites.

The liquid chromatograph and mass spectrometer conditions were optimized for the nine synthetic cannabinoid metabolites, including the mobile phase gradient and Multiple Reaction Monitoring (MRM) transitions. The LC conditions included a ten-minute run with initial conditions of 70:30 ratio of 0.1% formic acid in water (mobile phase A) and 0.1% formic acid in methanol (mobile phase B). Over eight minutes, the ratio switched to 10:90 of A:B and was then held for one minute, before re-equilibrating to the starting conditions at 9.1 minutes. The method achieved baseline separation and identification was based on their MRM transitions. Calibration models were produced in the range of 1ng/mL-100ng/mL for JWH-018, UR-144, AKB-48, PB-22, and 5F-PB-22 metabolites; 1ng/mL-50ng/mL for ADBICA, AB-PINACA, and ADB-PINACA metabolites; and 5ng/mL-100ng/mL for BB-22 metabolite ($R^2 > 0.98$). The limits of detection were at or less than 2ng/mL and limits of quantitation were at or less than 5ng/mL. The method was validated using Scientific Working Group for Toxicology (SWGTOX) guidelines for quantitative methods and once the method was validated, it was applied successfully to authentic urine samples. The range for authentic samples was 2ng/mL-250ng/mL. Specificity was determined by testing possible compounds that could produce a possible interference and then comparing the true negatives to the sum of samples that were true negatives and false positives. This method will be of use to the field of forensic toxicology as it incorporates a method to test for the consumption of currently scheduled compounds and recently emerging synthetic cannabinoids.

Synthetic Cannabinoids, Urine, LC/MS/MS

K9 Recreational Drug Use Trends and Emerging Analytes Identified in Blood, Urine, and/or Oral Fluid From Attendees at an Electronic Dance Music (EDM) Festival

Amanda L.A. Mohr, MSFS, Center for Forensic Science, Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Jillian K. Yeakel, MS, 3864 Courtney Street, Ste 150, Bethlehem, PA 18017; Melissa Frisica, MSFS, Center for Forensic Science Research and Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to assess and review the trends of recreational drug use generated by survey data and analytical testing of biological samples and compare user accounts of what they are ingesting with toxicological results within an EDM population.

This presentation will impact the forensic science community by providing data on the extent and nature of emerging analytes. Additionally, attendees will be able to discuss trends in Novel Psychoactive Substance (NPS) use within this population, which have not previously been studied in the United States.

EDM is a popular music genre in Europe and the United States and has a strong association with various specific types of drug use, especially NPSs, which is documented by surveys with EDM attendees and is reflected in online discussion groups associated with EDM culture. EDM festivals within the United States have recently been a focus of media attention due to drug-related deaths and mass hospitalizations or medical aid calls, which have caused cancellations of the events. The use of these novel and potentially toxic drugs within these venues makes EDM festivals an important site to collect information regarding recreational drug use and potentially characterize emerging analytes.

Participants were recruited during an EDM festival in Florida in 2014. The study received institutional review approval for human subject studies. After obtaining informed consent, each participant filled out a brief questionnaire regarding prescription medication and recreational drug use within the last week. Participants were asked to provide a blood, urine, and two oral fluid samples for laboratory-based drug screening and confirmation. One oral fluid sample was collected for presumptive screening using the Alere® DDS2 Mobile System and the other was collected with an Immunalysis Quantisal™ collection device for subsequent laboratory-based confirmatory analysis.

A total of 145 volunteers participated in the sample collection. The average age of the study participants was 23 years old. Not all subjects provided all three biological samples. Sixty-six blood samples, 105 urine samples, 125 oral fluid samples for the Alere® DDS 2, and 136 oral fluid samples for the Quantisal™ were provided by the participants. Blood samples were screened using Liquid Chromatography/Quadrupole/Time-Of-Flight/Mass Spectrometry (LC/Q/TOF). All urine specimens were screened via several analytical techniques including Enzyme Multiplied Immunoassay Technique (EMIT), Gas Chromatography/Mass Spectrometry (GC/MS), and LC/Q/TOF. The oral fluid sample collected for the Alere® DDS 2 Mobile System was screened on-site for the presence of cannabis, cocaine, opiates, methamphetamine, amphetamine, and benzodiazepines. Alcohol was confirmed and quantitated using a headspace GC/Flame Ionization Detector (GC/FID) for all blood and urine samples. Any sample which screened positive was sent for confirmation.

When asked whether or not the individual had taken any medicinal or recreational drugs within the past week, 70.7% of the participants answered “yes.” The most common substance participants indicated they had taken was marijuana (n=60), followed by cocaine (n=17). In terms of NPS, compounds like MDMA (3,4-methylenedioxy-N-methylamphetamine), “Molly,” and/or “ecstasy” were reported to have been used within the past week by 33 participants. Forty blood samples have been screened using LC/Q/TOF. Thirty percent of the blood samples (n=40) screened positive for at least one NPS drug. Of the 104 urine samples screened, only 16% were completely negative for the presence of any drugs and/or alcohol. Twenty-one percent of the urine samples were positive for a single drug, while 35% were positive for polydrug use. Approximately 40 urine samples screened positive for an NPS drug, with more than 80% confirming positive for which there was an analytical assay available. One hundred twenty-two oral fluid samples screened positive using the Alere® DDS 2. The two most common positive results were for cannabis (22%) and cocaine (10%).

Toxicology Section - 2015

The EDM festival culture has been largely understudied in the United States; however, this population has proved to be an invaluable resource in terms of learning about patterns of recreational drug use and emerging NPS. Data on which drugs are being ingested at these events can be useful for educating users about risks associated with NPS, provide opportunities for harm reduction, and enable forensic laboratories to target testing strategies for impairment or death investigations associated with these events.

NPS, Electronic Dance Music, Drug Testing

K10 Evaluation of Cases Admitted to Cukurova University Forensic Toxicology Laboratory From June 2009 to June 2014: A Retrospective Study

Pinar Efeoglu, MS, Cukurova University School of Medicine, Dept of Forensic Medicine, Balcali, Adana 01330, TURKEY; Nebile Gokce Daglioglu, PhD, Cukurova University, Faculty of Medicine, Dept of Forensic Medicine, Adana 01130, TURKEY; Mete K. Gulmen, PhD, MD, Cukurova University, School of Medicine, Dept of Forensic Medicine, Adana, 01330, TURKEY; Ismail E. Goren, BS, Cukurova University, Dept of Forensic Medicine, Balcali, Adana 01330, TURKEY; and Ahmet Hilal, MD, Çukurova Üniversitesi, School of Medicine, Forensic Medicine Dept, Adana, 01330, TURKEY*

After attending this presentation, attendees will better understand the gender, variety, and number of cases received per year to the Cukurova University Forensic Toxicology Laboratory in southern Turkey, which serves both the clinical and judicial fields.

This presentation will impact the forensic science community by informing attendees of the wide diversity of substances analyzed in the Cukurova University Forensic Toxicology Department.

Cukurova, with its historical name “Mediterranean”, covers Adana, Mersin, Osmaniye, and Hatay provinces and has geographical, economical, and cultural importance. One of the largest population densities of Turkey belongs this area with its seven million people. Throughout history, Cukurova has been an escape point from Europe to the Middle East, and the short transition point from North Middle East to Central Asia. It is also the center of transportation with its two main harbors.

Cukurova University Hospital is located in this region and provides service to surrounding subregions. Cukurova University Forensic Toxicology Laboratory is a unique academic unit that works in the field of forensic and clinic toxicology. Analysis of drugs of abuse, pesticides, volatile substances, and alcohol and carbon monoxide poisoning are performed in biological samples such as blood, urine, hair, and nails by using gas chromatography/mass spectrometry, liquid chromatography/tandem mass spectrometry, headspace gas chromatography, and ultraviolet spectrophotometry. Not only forensic samples but also routine hospital toxicology analyses are performed in this laboratory.

In this study, archives of cases received in this forensic laboratory during the period of June 2009-June 2014 were investigated. Cases were classified according to gender, applied unit, type of substances, and distribution of cases by year. Findings were statistically evaluated by the Statistical Package for the Social Sciences (SPSS) v20.0 software program.

After screening five years of data, it was determined that the number of cases gradually increased every year. A total of 865 cases were evaluated and it was found that 52.3 % of the cases admitted to the toxicology laboratory were clinical, 43.2 % were forensic samples, 2.8% were special request, and 1.7 % were from surrounding hospitals; 74.2 % were male and 25.8 % were female. Furthermore, it was found that 50.2 % of 452 clinical cases were from an emergency department, 22.3 % were from pediatric patients, 12.4 % were from psychiatry patients, 9.7 % from neurology, and the remainder were from other units of the hospital.

Of the 374 forensic cases received, 95.7 % were for drugs of abuse and 4.3 % were for alcohol. Tetrahydrocannabinol (THC) is the most widely determined substance in drug abuse cases and amphetamine and derivatives were commonly used in combination with THC.

Pesticide poisoning is also common due to one of the main sources of agriculture. Spraying for insects is carried out in March, April, and May in the region, so poisoning cases are more frequent in these months.

Carbon monoxide intoxication was more frequent in wintertime than in summertime due to household heating. The number of women who were exposed to carbon monoxide was greater than men, likely because women were much more frequently at home.

This study will present a retrospective study in terms of identification of cases received by Cukurova University Hospital Toxicology Laboratory.

Forensic Toxicology Lab, Demography, Cukurova University

K11 Analysis of the Anticoagulant Brodifacoum in Serum After an Incident of Pesticide Poisoning

*Stephen J. Melito, DO**, 92 Morgan Place, East Brunswick, NJ 08816; *Donna M. Papsun, MS*, 607 S Olds Boulevard, Fairless, PA 19030; and *Daniel S. Isenschmid, PhD, NMS Labs*, 3701 Welsh Road, Willow Grove, PA 19090

After attending this presentation, attendees will better understand the presentation of pesticide poisoning by brodifacoum from a clinical setting as well as with the analysis of brodifacoum in biological specimens.

This presentation will impact the forensic science community by illustrating how the combination of clinical diagnostics and forensic toxicology appropriately identifies a poisoning agent.

In 2008, the Environmental Protection Agency tightened restrictions on consumer-available rodenticides due to substantial risks posed to humans. Brodifacoum, a second-generation anticoagulant rodenticide, along with bromadiolone, difenacoum, and difethialone, are no longer available in less than one pound packaging marketed to the consumer.¹ Labeled as superwarfarins, these compounds are hazardous in humans due to their long half-life anticoagulation effects which cause excessive bleeding. Commercially, brodifacoum is the most commonly used in commercial rodenticides at a concentration of 0.005% and there have been reports of accidental and intentional poisonings by brodifacoum.

A 47-year-old woman with no history of bleeding disorder developed nausea and vomiting without diarrhea after eating at a restaurant. One week later, she discovered dark blood-like urine which prompted her to go to the emergency room. She underwent an Esophagogastroduodenoscopy (EGD) during her hospitalization with no complications. Post-procedure, she developed gum bleeding and coagulation labs revealed a Prothrombin Time (PT) of >120s with an International Normalized Ratio (INR) of >9.9 and a Partial Thrombin Time (PTT) of 147.8s. PT and PTT corrected with mixing study. The patient was also found to have bleeding into the collecting system of the kidneys. She received four units of Fresh Frozen Plasma (FFP) before being transferred to another hospital for higher level care and workup. She denied any personal or family history of bleeding disorders and had multiple surgical procedures in the past without any bleeding complications. She also noted no gum bleed, epistaxis, or previous history of hematuria or hematochezia. Coagulation studies showed a decrease in vitamin K dependent factors II, VII, XI, and X of 26%, 4%, 14% and 31%, respectively. Initially her INR corrected with FFP and daily vitamin K but became elevated again two days later despite daily vitamin K. Again her INR was corrected with FFP and with an increased dose of both oral and Intravenous (IV) vitamin K. A super warfarin was suspected.

A qualitative anticoagulant poisoning panel was performed on serum that confirmed positive for brodifacoum. Other analytes in this panel include warfarin, dicumarol, diphacinone, chlorophacinone, difenacoum, and bromadiolone. The extraction of brodifacoum from serum was achieved using protein precipitation by acetonitrile after the addition of chloro-warfarin as the internal standard. Then a solvent extraction was completed using Methyl Tert-Butyl Ether (MTBE); the organic layer was dried down and reconstituted with an 80:20 mix of 0.02% ammonium hydroxide in deionized water and 0.02% ammonium hydroxide in methanol. Analysis was achieved by using High-Performance Liquid Chromatography (HPLC) separation on a BEH C18 column with negative-ion Electrospray Tandem Mass Spectrometry (LC/MS/MS) for detection. The transitions monitored for brodifacoum were 523.1>135.1 and 523.1>80.9. Values that exceeded the method cut-off of 10ng/mL were reported as positive. The response of the sample was approximately 30x that of the cut-off calibrator.

The patient denied any exposure to rat poison and did not feel anyone was trying to poison her. She denied any current suicide attempts but did state an attempt five years prior by overdosing on her antidepressants. She was cleared by psychiatry. The case was reported to the state poison control center and health department. Also the patient's local law enforcement was notified of the findings. She was cleared by the hospital's risk management department and social work department and discharged on daily vitamin K with weekly follow-ups as an outpatient for INR levels.

Brodifacoum, Pesticides, Poisoning

K12 Effect of Sunlight on Methamphetamine in Urine

Dickens Wong Vui Foo*, Jabatan Kimia Malaysia, Rose Garden, Jalan Penampang, 88300 Kota Kinabalu, Sabah, MALAYSIA

After attending this presentation, attendees will understand the effect of sunlight exposure time to the methamphetamine concentration in urine.

This presentation will impact the forensic science community by providing results in an area with very little previous research. This presentation will discuss one of the factors that can affect the concentration of methamphetamine in urine.

Malaysia is a tropical country close to the equator and has hours of abundant natural sunshine almost every day. The strong sunlight could damage goods. Hence, forensic toxicology chemists are often challenged by lawyers in drug abuse trials concerning the accuracy of the analytical result, especially in cases where the specimen of the accused was kept in the enforcement officer's office or in a car exposed to sunlight during the transportation to the toxicology laboratory. The possibility of decomposition or degradation of a drug in the urine specimen by sunlight has become an issue.

In this study, the stability of methamphetamine in urine was evaluated after various exposure periods of sunlight. Nine urine specimens (marked "M1" to "M9") containing 1ug/mL to 5ug/mL methamphetamine were chosen for this study. The presence of methamphetamine in the urine specimens was identified by gas chromatography mass spectrometry prior to the transfer of 1mL of each specimen to a 2mL microtube. Twenty microtubes were prepared for each specimen. All prepared microtubes were capped properly and placed in the sun from 10:00 a.m. to 3:00 p.m. every sunny day. The microtubes were kept in a chiller after the experiment. One microtube from each specimen was collected when the preset interval period of the sunlight exposure had been attained. The concentration of the analyte after exposure to 5-310 hours of sunlight was determined by Enzyme Linked Immunosorbent Assay (ELISA) technique.

Results showed that the concentration of methamphetamine in all urine specimens decreased as the sunlight exposure time increased. No methamphetamine was detected in specimen M1 to M7 after 255 hours of sunlight exposure. The methamphetamine in M8 and M9 decreased in accordance with M1 to M7, and would likely be negative for methamphetamine if the sunlight exposure time was increased further. Although the temperature of the urine increased during the sunlight exposure process, previous research suggested that there was no significant effect of temperature to the loss of methamphetamine in urine.^{1,2} In conclusion, sunlight could reduce the concentration and eliminate the methamphetamine in urine and exposing the urine specimen to sunlight, especially for a long period, should be avoided.

Methamphetamine, Sunlight, Urine

K13 Analysis of Buprenorphine, Norbuprenorphine, Naloxone, and Their Glucuronides From the Urine Obtained in Drug and Driving Cases

Jeffery Hackett, PhD*, UCT, 2731 Bartram Road, Bristol, PA 19007; and Albert A. Elian, MS*, Massachusetts State Police Crime Lab, 59 Horsepond Road, Sudbury, MA 01776

After attending this presentation, attendees will better understand choosing the most efficient method for extracting buprenorphine, norbuprenorphine, naloxone, and related glucuronides from urine employing available Solid Phase Extraction (SPE) cartridges and Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS). Buprenorphine is being requested more often as a test in drug and driving cases. Buprenorphine does not cross-react with typical opiate immunoassays and cannot be detected in basic drug screens using Gas Chromatography/Mass Spectrometry (GC/MS) without derivatization. LC/MS/MS does offer an efficient alternative to GC/MS.

This presentation will impact the forensic science community by offering analysts operating in forensic facilities information regarding the extraction and analysis of buprenorphine, norbuprenorphine, naloxone, and the related glucuronides in urine samples obtained in drug and driving cases using SPE and LC/MS/MS. These drugs are now regularly being encountered in drug and driving casework and this method will greatly assist analysts in offering better interpretation to submitting agencies.

Method: 1mL samples of urine (calibrators, controls, and test samples each containing deuterated internal standards) were diluted with 3mL of 0.1M aqueous phosphate buffer (pH 6), vortex mixed and centrifuged. The supernatant liquid was applied to a pre-conditioned SPE mixed mode (C8/SCX) column. The SPE columns were conditioned with methanol, Deionized (DI) water and 0.1M phosphate buffer (3mL, 3mL, 1m, respectively). After loading samples at 1mL/minute, the SPE cartridges were washed with DI water, 1.0M acetic acid, and methanol (3mL of each, respectively). The SPE columns were dried and eluted with 3mL of a solution containing methylene chloride-isopropanol-ammonium hydroxide (78-20-2) and 3mL of a solution of methanol containing 4% ammonium hydroxide. The eluates were collected separately and combined to form one solution. The eluate solutions were evaporated to dryness under nitrogen at 35°C. The dried residues were dissolved in 100µL of mobile phase for LC/MS/MS. LC was performed in gradient mode employing a 50mm x 2.1mm (2.1µm) aromatic phase LC column using mobile phase consisting of acetonitrile and 0.1% aqueous formic acid at a flowrate of 0.5mL/minute.

Tandem mass spectrometry was performed in positive Multiple Reaction Mode (MRM). The following transitions were monitored (quantification transition ions underlined): buprenorphine (468.3 to 396.2, 414.3), buprenorphine-d4 (472.5 to 400.1, 415.3), Norbuprenorphine (414.3 to 340.1, 326.0), norbuprenorphine-d3 (417.3 to 343.4, 326.0), naloxone (328.2 to 253.0, 212.1), respectively. The glucuronides were monitored as follows: buprenorphine glucuronide (644.3 to 468.1, 396.3), norbuprenorphine glucuronide (590.3 to 414.3, 396.2), naloxone glucuronide (335.2 to 299.1, 273.1), naloxone-d5 (332.1 to 258.1, 273.1), respectively. In this presentation, representative chromatograms are shown to illustrate the efficiency of the chromatography and analysis of buprenorphine, norbuprenorphine, naloxone, and related glucuronides from 20 (completed) drug and driving cases

Results: The limits of detection/quantification for this method were determined to be 5ng/mL and 10ng/mL, respectively, for all of the analytes (i.e., buprenorphine/norbuprenorphine/naloxone, and glucuronides). The method was found to be linear from 10ng/mL to 1,000ng/mL ($r^2 > 0.999$). The analyte recoveries were found to be greater than 95% for all of the noted compounds. Interday and Intraday variation of the method were found to <8% and <10%, respectively. Matrix effects were determined to be <6%. Details regarding the concentrations of buprenorphine/norbuprenorphine/naloxone found in 20 genuine urine cases are presented.

Conclusion: This method demonstrates the efficient use of both SPE coupled with the use of LC/MS/MS for the analysis of buprenorphine/norbuprenorphine/naloxone and their related glucuronides in cases of driving under the influence of drugs. The ability to analyze buprenorphine, norbuprenorphine, naloxone, and their glucuronides in drug and driving cases will greatly assist toxicologists in offering the appropriate interpretation to the submitting agencies.

Buprenorphine Glucuronide, Naloxone, SPE

K14 Validation of the Neogen® Enzyme-Linked Immuno-Sorbent Assay (ELISA) Fentanyl Ready-to-Use (RTU) Kit for Whole Blood and Urine Specimens

Kristin E. Wegner, BS, Palm Beach County Sheriff's Office, 3228 Gun Club Road, West Palm Beach, FL 33406; and Nicholas B. Tiscione, MS, 3228 Gun Club Road, West Palm Beach, FL 33406*

After attending this presentation, attendees will understand the performance of the Neogen® ELISA Fentanyl RTU kit for screening whole blood and urine specimens as evaluated by the Scientific Working Group for Forensic Toxicology (SWGTOX) Standard Practices for Method Validation in Forensic Toxicology Laboratories guidelines.

This presentation will impact the forensic science community by demonstrating the validation of an ELISA method following SWGTOX guidelines.

Objective: The validation of a semi-quantitative method for the rapid screening of whole blood and urine specimens by a Dynex DSX® Automated ELISA System using the Neogen® Fentanyl (RTU) Kit.

Method: Neogen® Fentanyl kit assay instructions for incubation times, reagent volumes, and sample volumes were followed. Whole blood samples were diluted 1:5 with buffer before being loaded onto the instrument. Urine samples were diluted 1:2 with buffer by the instrument. Performance of the assay was evaluated at two decision points for each matrix (low control and cutoff control). Urine was evaluated at 1ng/mL and 5ng/mL and blood was evaluated at 0.5ng/mL and 1ng/mL. SWGTOX guidelines were followed for the validation of the assay. The validation included the evaluation of sensitivity, repeatability, specificity, carryover, plate drift, ruggedness/robustness, and a case sample comparison.

Results: Carryover was evaluated by running three replicates of a blank matrix control following a positive matrix control at 500ng/mL for both blood and urine. Carryover was not detected in the assay. The sensitivity for this method was evaluated by replicate analysis of a blank matrix control to determine the theoretical Limit Of Detection (LOD) and by the analysis of standards at successively lower levels to determine an experimental LOD. The theoretical LOD was determined to be 0.18ng/mL for blood and 0.03ng/mL for urine. The experimental LOD was determined to be 0.5ng/mL for both blood and urine assays. Repeatability was evaluated at 0.25ng/mL, 0.5ng/mL, 0.75ng/mL, 1ng/mL, and 1.5ng/mL for blood and 0.5ng/mL, 1ng/mL, 1.5ng/mL, 2.5ng/mL, 5ng/mL, and 7.5ng/mL for urine with three replicates at each level over five separate runs. The mean response ± 2 Standard Deviations (SD) at each decision point for both blood and urine did not overlap with the mean response ± 2 SD of standards prepared at $\pm 50\%$ of the concentration of the decision points. The repeatability was determined by calculating the Coefficient of Variation (CV) for 15 inter-run replicate measurements of each assay at each concentration. The CV was less than or equal to 3% for blood and 6% for urine. Specificity was evaluated in blood and urine by the analysis of negative matrix samples spiked at 250ng/mL, 500ng/mL, and 1,000ng/mL of norfentanyl and 5ng/mL, 10ng/mL, and 25ng/mL of acetyl fentanyl. Observed cross reactivity was similar to that stated by the manufacturer. For acetyl fentanyl, cross reactivity was between 29% and 35% for whole blood and between 50% and 59% for urine. For norfentanyl, cross reactivity was between 0.04 and 0.17% for whole blood and between 0.05 and 0.20% for urine. There were no false positives for fentanyl resulting from screening known samples, which contained morphine, hydromorphone, buprenorphine, hydrocodone, oxycodone, and oxymorphone. Two urine cases and one blood case containing fentanyl were positively identified. Plate drift was evaluated by analyzing 24 replicates at the concentration of the cutoff control for each matrix. The number of replicates analyzed was greater than the number of samples run in routine casework. Plate drift was not observed.

Toxicology Section - 2015

Whole Blood (n = 15)	Level (ng/mL)	Mean O.D.	SD	CV (%)	Mean + 2 SD	Mean – 2 SD
	0.25	1.848	0.029	1.6	1.906	1.790
Low Control	0.5	1.663	0.036	2.2	1.735	1.591
	0.75	1.528	0.026	1.7	1.580	1.476
Cutoff Control	1	1.379	0.029	2.1	1.437	1.321
	1.5	1.196	0.029	2.4	1.254	1.138
Urine (n = 15)	Level (ng/mL)	Mean O.D.	SD	CV	Mean + 2 SD	Mean – 2 SD
	0.5	1.451	0.042	2.9	1.535	1.366
Low Control	1	1.148	0.027	2.3	1.201	1.094
	1.5	0.984	0.020	2.0	1.024	0.943
	2.5	0.719	0.024	3.4	0.768	0.671
Cutoff Control	5	0.488	0.027	5.6	0.542	0.433
	7.5	0.371	0.008	2.1	0.386	0.355

Conclusion: The Neogen® Fentanyl ELISA kit is a highly sensitive, specific, and rapid screening procedure to detect fentanyl in blood and urine.

Fentanyl, Validation, ELISA

K15 Rapid Drug Screening Using a Combination of Flow Injection Tandem Mass Spectrometry (FI/MS/MS) and the Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) Method

*Kiyotaka Usui**, 2-1 Seiryomachi, Aoba-ku, Sendai, Miyagi, JAPAN; *Koichi Saito*, Sendai, Miyagi, JAPAN; *Tetsuo Kokaji*, Sendai, Miyagi, JAPAN; *Tomomi Aramaki*, Sendai, Miyagi, JAPAN; and *Masato Funayama*, Sendai, Miyagi, JAPAN

After attending this presentation, attendees will understand the usability of the combination of FI/MS/MS and the QuEChERS extraction method for rapid drug screening.

This presentation will impact the forensic science community by demonstrating a rapid detection method that reduces the time needed for the total drug screening process to approximately ten minutes. Using this method, toxicological findings can be returned to forensic pathologists during the autopsy process. Thus, the QuEChERS-FI/MS/MS combination method will facilitate determination of the cause of death and allow law enforcement to solve cases more quickly.

There is a compelling need for the rapid diagnosis of drug poisoning in both forensic and clinical toxicology. Currently, several drug-screening methods are available. For example, immunoassay techniques such as the Triage[®] kit are favored in forensic and clinical toxicology because results are obtained in a short time and sample pretreatment is not required; however, such methods can only be used to assay urine samples and can identify the class of drugs present, but not the drug of interest itself. Furthermore, these methods cannot measure all types of drugs and poisons and they have low sensitivity. Analytical methods such as Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) are also commonly used for drug screening; however, although these techniques have high sensitivity and selectivity and can detect a wide range of drugs and poisons, they usually require time-consuming sample pretreatment and column separation. From the start-up of the instruments to the reporting of the result, including analysis of the blank sample, a period of more than two hours is typical. While many studies have reported rapid drug screening methods using LC/MS/MS, in practice most of these methods require considerable time from the start-up of the instruments to the reporting of the results. Additionally, the use of these techniques is somewhat difficult for less-experienced analysts. Therefore, the limiting factors were addressed by developing a reliable and simple analytical technique using a combination of the QuEChERS method and an FI/MS/MS system, which returns results within 10 minutes.

Whole blood samples were collected from practical forensic cases (N=79) and pretreated using the QuEChERS method.¹ Briefly, 0.5mL of whole blood was diluted three-fold with distilled water. The diluted sample was placed in a plastic tube with 0.5g of the pre-packed extraction kit reagent, a stainless steel bead, and 1mL of acetonitrile. The mixture was shaken for 30sec and centrifuged for 1min. The supernatant was transferred to a 2.0mL centrifuge tube containing the solid-phase extraction sorbent for sample cleanup. The tube was mixed for 10sec and centrifuged for 1min. The extract was analyzed by both LC/MS/MS and FI/MS/MS (analysis time=1.5min). All product ion spectra obtained by FI/MS/MS were automatically processed by Library View[™] software, and the results were compared with those of the LC/MS/MS analysis using Dice's coefficient.

The combination of QuEChERS and FI/MS/MS enabled completion of the entire drug screening process, from the start-up of the instruments through the extraction process and data analysis, within 10min. For actual forensic cases (N=79), the qualitative results roughly matched (96% concordance rate) with the results obtained with the standard LC/MS/MS technique. The false-positive rate with the combined QuEChERS-FI/MS/MS method was 3.4% and the false-negative rate was 3.9%. Although some drugs present at low concentrations were not detected in the analysis of forensic cases, the QuEChERS-FI/MS/MS method was able to detect a wide-range of drugs in whole blood in a relatively short time.

Flow Injection MS/MS, QuEChERS Extraction, Rapid Drug Screening

K16 Detection of Amitriptyline and Nortriptyline in Decomposed Skeletal Tissues by Microwave-Assisted Extraction and Ultra High-Performance Liquid Chromatography

Heather M. Cornthwaite, MSc, 935 Ramsey Lake Road, Sudbury, ON P3E2C6, CANADA; Caroline C. Betit, MSc, 935 Ramsey Lake Road, Sudbury, ON P3E 2C6, CANADA; and James Watterson, PhD, Laurentian University, 935 Ramsey Lake Road, Sudbury, ON P3E 2C6, CANADA*

After attending this presentation, attendees will understand how to develop a microwave-assisted extraction methodology using bone tissue and be provided with an example of its practical application using vertebral bone.

This presentation will impact the forensic science community by adding to the body of data illustrating the utility of skeletal tissues as a matrix for toxicological analysis and by demonstrating an efficient method for preparation of skeletal tissue samples.

The use of Microwave Assisted Extraction (MAE) followed by Microplate Solid Phase Extraction (MPSPE) and Ultra High Performance Liquid Chromatography (UHPLC) to detect Amitriptyline (AMI) and Nortriptyline (NORT) from postmortem skeletal tissues is described. Rats (n=4) received 60mg/kg amitriptyline and were euthanized by CO₂ asphyxiation approximately 20min post-dose. The remains decomposed to skeleton outdoors and vertebral bone was collected. Bones were cleaned with phosphate buffer (PBS, 0.1M, pH 6), methanol, and acetone, then dried under ambient conditions and pulverized to a powder. Bone samples (n=3, 0.5g), as well as one drug-free sample, underwent MAE using methanol in a closed vessel system for a total of 60 minutes. The extraction solvent was replaced with fresh methanol after 10, 20, 30, and 60 minutes of irradiation. The methanolic extracts were evaporated and reconstituted in 1mL PBS. Internal standard (Desipramine, DMI, 500ng) and 100µL glacial acetic acid were added to each extract. Acetonitrile:methanol (1:1, 3mL) was added to each extract, followed by storage at -20°C overnight to precipitate proteins and lipids. Following centrifugation, the supernatants were evaporated to 1mL, diluted to 3mL using PBS and acidified with 100µL glacial acetic acid.

Diluted supernatants underwent further clean-up by MPSPE, using CleanScreen® XCEL™ 1 48 well plates. Wells were conditioned with methanol (3mL), distilled water (3mL) and PBS (3mL). Following loading of samples, columns were washed with PBS (3mL) and 0.1M acetic acid (3mL). Columns were dried (~5 in Hg, 5min) and washed with methanol (3mL). Columns were then dried again under vacuum (~10 in Hg, 10min). Basic compounds were eluted with 3% NH₄OH in 20:80 isopropanol: dichloromethane (3mL). Extracts were evaporated to dryness and reconstituted in 0.1% formic acid in 10:90 acetonitrile:water (500µL). Samples were analyzed using an Acquity UHPLC with a Photo-Diode Array (PDA) detector. The column used was a Selectra DA (100mm x 2.1mm, 3.0µm particle size). Samples were run using a binary gradient elution (A: 0.1% (v/v) formic acid, 10% (v/v) acetonitrile, and 90% (v/v) water; B: 0.1% (v/v) formic acid, 10% (v/v) water, and 90% (v/v) acetonitrile). The mobile phase gradient began with 90:10 A:B, held for 3min, followed by a linear increase to 40:60 A:B over 8min, followed by reversion back to 90:10 over 1min for a total run time of 11min at a constant flow rate of 0.300mL/min. The autosampler was maintained at 25°C, with the column temperature set to 50°C. The wavelengths chosen for analysis were 245nm for AMI and NORT as well as 290nm for DMI. Analyte stability to MAE in methanol was assessed and both analytes were stable for at least 60mins irradiation time. Recovery was at least 95% of maximal value within the first 10min of MAE for all samples assayed. The MPSPE/UHPLC method was linear between 25-10,000ng/mL, with precision and accuracy <20% in triplicate analyses, with a limit of detection of 25ng/mL for both AMI and NORT. The vertebral bone analyzed using this method detected AMI (2.8µg/g -15µg/g) and NORT (1.8µg/g-4.3µg/g) in all samples assayed.

Forensic Toxicology, Bone, Microwave-Assisted Extraction

K17 A Validated Method for the Determination of Salvinorin A and Salvinorin B in Forensic Toxicology Samples

Sarah Kerrigan, PhD, Sam Houston State University, 1003 Bowers Boulevard, SHSU Box 2525, Huntsville, TX 77341; and Tracy Gastineau, MS*, 24819 Bridgewater Drive, Magnolia, TX 77355

After attending this presentation, attendees will be able to describe a simple and effective way to identify salvinorins in urine using Solid Phase Extraction (SPE) and Gas Chromatography/Mass Spectrometry (GC/MS).

This presentation will impact the forensic science community by providing a scientifically validated method for the determination of Salvinorin A and B in urine.

Salvia divinorum is a perennial plant from the Lamiaceae (mint) family found in the Sierra Mazateca region of Oaxaca, Mexico, and has been used in religious and medicinal rituals for centuries. *Salvia divinorum* is also used as a recreational drug due to its profound hallucinogenic properties. As many as 35 countries have enacted legislation to control *S. divinorum* and/or salvinorin A, its principal psychoactive component. Street names include Diviner's Sage, Maria Pastora, Sally-D, and Magic Mint. Salvinorin A and its major metabolite (Salvinorin B) are of forensic interest, but are rarely reported during routine toxicological testing. Salvinorin A is the only known naturally occurring non-nitrogenous hallucinogen with a high affinity for the Kappa-Opioid Receptor (KOR). Although it is not federally controlled at present, its rapid onset of action and powerful hallucinogenic effect contribute to its abuse potential.

An optimized and scientifically validated method for the determination of salvinorin A and salvinorin B in biological matrices is reported. SPE and GC/MS using Selected Ion Monitoring (SIM) were used throughout. Both the extraction method and GC/MS parameters were optimized to achieve optimal chromatographic separation and detection. In the absence of a commercially available deuterated salvinorin at the time of the study, testosterone-D3 was used as the internal standard. A GC inlet temperature of 250°C and an initial oven temperature of 260°C produced optimal results. The temperature program involved a 0.5min hold at 260°C with a ramp up to 290°C with a 30°C/min rate and a final hold for 17 minutes. The retention times were 6.9min for Salvinorin B and 7.9min for Salvinorin A.

The method was evaluated using recommendations of the Scientific Working Group for Toxicology (Scientific Working Group for Forensic Toxicology (SWGTOX) standard practices for method validation in forensic toxicology, 2013). Analytical recovery, limit of linearity, limit of detection, quantitation, precision, bias, carryover, interference, and dilution integrity were evaluated. Both Salvinorin A and Salvinorin B were linear from 0ng/mL-1,000ng/mL. The limits of detection and quantitation for Salvinorin A were 5ng/mL and 10ng/mL, respectively. The limit of detection for Salvinorin B was 20ng/mL. Precision and bias were evaluated at three concentrations and produced %CVs and bias of <20%. Carryover was not present at 1,000ng/mL and no interferences were observed from common drugs of abuse. Interferences from other salvinorins and divinatorins were also evaluated. Dilution integrity was evaluated using biological matrices that were diluted 1:10 prior to SPE. These results also demonstrated acceptable precision and bias. This validated method provides an efficient and reliable method to quantitatively identify salvinorins of forensic interest in biological matrices using GC/MS.

Salvinorin A, GC/MS, Urine

K18 Identification of Methcathinone in Urine by Gas Chromatography/Mass Spectrometry (GC/MS) Using a One-Step Simultaneous Dispersive Liquid-Liquid Extraction (LLE)/Cyclohexanone Derivatization

*Jennifer Leach**, 840 S 12th Street, Apt 7, Allentown, PA 18103; *Thomas A. Brettell, PhD*, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and *Brandi Skymba*, 162 E Phillips Street, Coaldale, PA 18218

After attending this presentation, attendees will have a better understanding of how cyclohexanone can be used as a simultaneous extraction and derivatizing agent.

This presentation will impact the forensic science community by providing a simple one-step dispersive (LLE)/derivatization method using GC/MS to identify methcathinone in urine.

Over the last decade, abuses of prescription and illegal drugs have caused serious problems in the United States. Recently a new class of drugs, known as synthetic cathinones, has spread worldwide. These synthetic cathinones are marketed as “bath salts,” “legal high drugs,” and “plant food.” Synthetic cathinones are beta-ketone phenylalkylamine derivatives and are often termed “bk-amphetamines” for the beta-ketone moiety. One of the synthetic cathinones that has been abused illegally is methcathinone. Crime laboratories are in need of methods to detect and identify these drugs not only in solid-dosage form but also in biological fluids such as urine from suspects of driving under the influence.

Skymba and Brettell have previously investigated cyclohexanone as a derivatizing reagent for cathinones using GC/MS.¹ A method was developed using cyclohexanone to form the Schiff-base derivative, creating a more complicated mass spectrum and better separation of the synthetic cathinones. This GC/MS method was developed to screen, identify, and differentiate 11 similar cathinone compounds often present in illicit drug submissions to crime laboratories. Primary and secondary amines will react with cyclohexanone via a Schiff-base reaction to form two distinct, different types of derivatives. Cyclohexanone forms an imine derivative with primary amines and enamine derivatives with secondary amines. The method was found to be reproducible and can be used to screen unknown samples and identify multiple cathinones in one sample.

In this presentation, a method will be described which expands the role of the cyclohexanone to an extraction solvent as well as a derivatizing agent. The method uses 300uL of cyclohexanone as the extraction solvent in a one-step dispersive LLE/derivatization in which methcathinone can be detected and identified from 1mL of urine using GC/MS.

In this method, the GS oven temperature parameters were set with an initial temperature of 120°C which then increased 15°C/min to 275°C. The column used was a 30m x 0.25mm x 0.25µm phenylmethylsilicone capillary column (Rxi®-5Sil MS) using helium as a carrier gas with a linear gas velocity of 36cm/sec. Cyclohexanone was used as the solvent and a sample volume of 1µL was injected in the split mode with a split ratio of 22:1. A retention-time optimization study provided the most advantageous separation conditions with methcathinone eluting with a retention time of 14.3 minutes using these conditions.

A simple, one-step dispersive LLE/derivatization method will be presented that uses cyclohexanone as the extraction solvent and GC/MS to identify methcathinone in urine.

Brettell, Ph.D., “Investigation Into Cyclohexanone as a Schiff-Base Derivatizing Agent for the Detection of Cathinones with Gas Chromatography/Mass Spectrometry,” Abstract #A204, Proceedings of the American Academy of Forensic Sciences, 65th Annual Scientific Meeting, Washington, DC. 2013.

Forensic Toxicology, Methcathinone, Dispersive LLE

K19 Quantitative Analysis of Methylphenidate (Ritalin®) and Ritalinic Acid in Oral Fluid by Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS)

Carmen T. Mulet, BS, IFRI/FATF, 11200 SW 8th Street, Miami, FL 33199; Lorena A. Leon, 12940 SW 64 Lane, Apt 304, Miami, FL 33183; Luis E. Arroyo, PhD, Florida International University, Modesto Maidique Campus, 11200 SW 8th Street, OE-107, Miami, FL 33199; and Anthony P. DeCaprio, PhD, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Miami, FL 33199*

The goal of this presentation is to introduce attendees to the use of human oral fluid for the quantitation of Methylphenidate (MPH) and its major metabolite, Ritalinic Acid (RA), through chromatographic and mass spectral analysis. Attendees will be familiarized with the advantages of a non-conventional biological matrix when applied to the forensic and clinical monitoring of these drugs.

This presentation will impact the forensic science community by informing attendees about an efficient, simple, and fast analytical procedure utilizing a non-invasive technique for monitoring MPH and RA in human oral fluid via the introduction of a dilute-and-shoot LC/QqQ/MS method of analysis.

MPH is an amphetamine derivative commonly used in the treatment of Attention-Deficit Hyperactivity Disorder (ADHD) in children, adolescents, and adults, a condition affecting 3%-5 % of the United States population. The 2011 National Survey of Children's Health reported that 11% of children aged 4-17 years were diagnosed with ADHD by a health care provider in the United States, with 6.1% of children in that age group having been prescribed medication for treatment of ADHD. In recent years, methylphenidate HCl has become one of the most frequently abused prescription drugs due to its psychostimulant effects. In addition, the drug has become popular with college students as a "study drug." According to the Drug Abuse Warning Network (DAWN) Report, the number of emergency department visits involving the non-medical use of ADHD-stimulant medications increased from 5,212 to 15,585 between 2005 and 2010. When administered orally, MPH is rapidly absorbed and hydrolyzed to its inactive metabolite RA. Current analytical methods for analysis of MPH and RA involve the analysis of blood and urine matrices using liquid-liquid extraction, solid-phase extraction, and Gas Chromatography/Mass Spectrometry (GC/MS). These methods are time consuming and sample collection is invasive and tedious. Due to the rising abuse of MPH, development of quick and non-invasive monitoring methods is important.

This presentation will demonstrate human oral fluid as a suitable matrix for analysis of MPH and RA using Electrospray Ionization (ESI) Liquid Chromatography/Mass Spectrometry (LC/MS) as a sensitive and specific method for screening and quantitation. Oral fluid samples were collected using an oral fluid collection device containing a cotton pad. They were vortexed, centrifuged for 30min at 3,200rpm and filtered into polypropylene serum tubes. The extracts were stored at -20°C until use. An Agilent 6460 triple quadrupole MS-equipped with Jet Stream ESI technology was used in the triggered Multiple Reaction Monitoring (MRM) mode for the characterization of the analytes. The ESI source was operated at 325°C in positive mode, with an optimized fragmentor voltage of 75V. The tMRM transitions were 234→84 and 234→56 for MPH and 220→84 and 220→56 for RA, with a cycle time of 500ms. The advantage of using multiple transitions is suggested as a fingerprint mass spectral tool for unambiguous identification of the target compounds. Gradient elution was performed on a Poroshell 120 EC-C18 column (2.1 x 100mm x 2.7µm) using MeOH+0.1% formic acid as organic phase and 5mM ammonium formate + 0.1% formic acid as phase modifier, with a total run time of 5min. Six-point linear calibrations with a weight of 1/x based on the internal standards (+)-methylphenidate-d9 HCl and (+)-threo-Ritalinic acid-d10 HCl, ($r^{23}0.99$) were obtained for concentrations between 0.50ng/mL and 100.00ng/mL for the drugs of interest, with quality controls showing an RSD<13%. The limits of detection for MPH and RA were 0.20ng/mL and 0.30ng/mL, respectively, indicating the validity of the method for identification and confirmation at low concentrations.

Methylphenidate, LC/QqQ/MS, Oral Fluid

K20 Assessment of Three Time-of-Flight/Mass Spectrometry (TOF/MS) Drug Screening Technologies Using Different Fragmentation Modes

Helen Piper, BS, 3550 Bartram Road, #31, Willow Grove, PA 19190; Alexander L. Maggitti III, BS, 3701 Welsh Road, Willow Grove, PA 19090; Jared Castellani, BS, 150 Ridge Pike, #108-A, Lafayette Hill, PA 19444; Francis X. Diamond, BS, 3701 Welsh Road, Willow Grove, PA 19090; Matthew M. McMullin, MS, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe and distinguish between three different fragmentation techniques in Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS) instrumentation and assess their utility for different types of toxicological analyses.

This presentation will impact the forensic science community by describing novel approaches to improving the sensitivity and specificity of emerging TOF/MS instrumentation in the forensic toxicology laboratory and by assisting laboratory managers and technical staff in selecting the appropriate instrumentation for specific analyses.

There is increasing interest in the use of High Resolution Accurate Mass Spectrometry (HRAMS) for toxicological drug screening. LC/TOF is a very powerful technique due to its increased specificity and sensitivity over immunological screening, its ease of sample preparation, and rapid run time compared to traditional Gas Chromatography/Mass Spectrometry (GC/MS) screening, and its capabilities for retrospective data analysis. Analysis by LC/TOF can be performed in multiple modes, all of which use a calculated exact mass based on the chemical formula of the parent compound and an expected retention time to identify analytes. Fragmentation allows for additional data characteristics to be used for identification thus eliminating some of the false positives caused by artifacts, minor metabolites, degradation products, drug analogs, and isomers. These false positives may lead to unnecessary confirmatory testing and/or an excess of candidate compounds requiring thorough data evaluation for a simple presumptive screening identification.

Three ionization modes were evaluated using an Agilent 1290 HPLC/6530 QTOF mass spectrometer with Jet Stream® technology for the screening of spiked postmortem samples and samples collected from an Electronic Dance Music (EDM) festival population for novel psychoactive substances as well as therapeutic drugs and traditional drugs of abuse. The modes were conventional Quadrupole Time-of-Flight (QTOF) and two All-Ions ionization modes: Collision-Induced Dissociation in the Source (CIDS) and Collision-Induced Dissociation in the Collision Cell (CIDCC). The conventional QTOF mode uses targeted MS/MS analysis, while the CIDS and CIDCC All-Ions modes provide fragmentation data through the use of alternating fragmentor voltages in the source or collision energies in the collision cell, respectively. The elution profiles of each of the ions, parents, and fragments are correlated for use in compound identification.

The All-Ions modes proved more advantageous for screening than the QTOF mode, especially for analytes present at lower concentrations. The QTOF mode is a data-dependent acquisition mode in which the MS/MS data collected for a particular sample is dependent on the precursor ions detected through MS data collection within the same injection. This leads to an increase in analysis time, a decrease in sensitivity, and an overall decrease in the amount of information obtained from a single injection; fewer data points are collected for each ion observed. The All-Ions CIDCC mode is similar to the QTOF mode in that the collision cell of the QTOF is utilized to generate mass spectra of precursor and fragment ions while the fragmentor voltage in the source is maintained at a low level preventing fragmentation prior to the collision cell; however, in this mode, the quadrupole is not used to filter for precursors observed; all ions within the mass range are passed to the analyzer for the entire run. The All-Ions CIDS mode cycles through the low and two higher source fragmentor voltages with the collision cell turned off thus allowing for collection of QTOF-like data using a conventional TOF instrument. Overall, both All-Ions modes performed better than the QTOF mode for broad-spectrum toxicological drug screening.

Toxicological Screening, TOF, QTOF

K21 Analysis of Phosphide Zinc and Aluminium Phosphide

Geetanjali Sachdeva, MSc, Forensic Science Lab, Haryana, 1329/13, Urban Estate, Kurukshetra 136118, INDIA*

After attending this presentation, attendees will better understand phosphide and how to diagnose it, especially Aluminium Phosphide (ALP). ALP is a potent poison and negligence in handling and transport can cause serious effects.

This presentation will impact the forensic science community by discussing the adverse effects of ALP, including how the number of ALP-related cases are increasing daily, especially in the northern region of India.

This abstract is based on analysis of ALP. Attendees will understand what the term toxicology means and the role of the forensic toxicologist expert. The word “toxicology” is derived from the Greek word “toxicon” which was used as a poisonous substance in arrowheads. Mathieu Orfila is considered to be the modern father of toxicology. The expertise of forensic toxicologists is primarily utilized in establishing the cause of death and elucidating its circumstances in postmortem investigation.

ALP is an inorganic phosphide used to control insects and rodents in a variety of settings. It is mainly used as an indoor fumigant at crop transport, storage, or processing facilities for both food and non-food crops. It may also be used as an outdoor fumigant for burrowing rodent and mole control or in baits for rodent control in crops. ALP is available in pellet and tablet form, in porous blister packs, sachets, or as dusts. ALP is generally known as a suicide poison; sometimes it is used in a homicide and occasionally it is accidentally ingested. It can easily be bought and has no effective antidote. Its toxicity results from the release of phosphine gas as the tablet gets into contact with moisture. Physical properties of ALP and zinc phosphide differ, as ALP is gray in color while zinc phosphide is black.

ALP can be detected in biological and non-biological matrices as well as other items taken from the scene of a crime. Viscera, postmortem blood, and other samples such as gastric lavage, clothes, etc. can be analyzed for ALP.

Diagnosis is made by clinical suspicion symptoms and history obtained from relatives, parents, and others. Sometimes the symptoms of poisoning are vague, even in fatal poisoning. This poison is mainly absorbed in the stomach and small intestine and some part may be passed out through excretion, sweat, and respiration. Chemical tests such as the silver nitrate test, alizarin test, and instrumental examination such as **Gas-Liquid Chromatography** (GLC) and biochemical examination of the gastric aspirate and viscera are carried out to diagnose phosphide poisoning. Treatment includes early gastric lavage with potassium permanganate or a combination of coconut oil and sodium bicarbonate, administration of charcoal, and palliative care. Specific therapy includes intravenous magnesium sulphate and oral coconut oil. Moreover, acidosis can be treated with early intravenous administration of sodium bicarbonate. This presentation will review the epidemiological, toxicological, and clinical/pathological aspects of ALP poisoning and its management.

Potent Poison, Diagnosis, Antidote

K22 A Total Sample Preparation Screening Solution for Acidic, Neutral, and Basic Drugs Using ISOLUTE® Multimode Solid Phase Extraction (SPE) Prior to High-Performance Liquid Chromatography With Tandem Mass Spectrometry (HPLC/MS/MS) Analysis

Victor Vandell, PhD, Biotage, 10430 Harris Oaks Boulevard, Charlotte, NC 28269; and Frank Kero, PhD, Biotage, 10430 Harris Oaks Boulevard, Ste C, Charlotte, NC 28269*

The goal of this presentation is to explain the evaluation of a multimode SPE sorbent for screening of acidic, basic, and neutral drugs from biological fluids.

This presentation will impact the forensic science community by demonstrating the utility of a multimode sorbent for effectively screening drugs of abuse from a variety of biological fluids.

Introduction: Sample preparation methodology that extracts and concentrates an analyte prior to analytical analysis is typically necessary to facilitate accurate quantitative and qualitative results. Typically, the sample preparation method is limited to drugs with the same functionalities (i.e., basic or acidic) to efficiently extract multiple drugs from matrices like urine. Here an all-encompassing method that can be used to extract a broad range of drugs independent of their functionality is described. The multimode silica based sorbent utilizes both a cationic and anionic functionality along with a hydrophobic mechanism to retain all of the drugs analytes prior to extraction and concentration.

Method: Urine and whole blood samples were spiked with a broad array of drug classes containing basic, acidic, and neutral functionalities. The drug classes examined were barbiturates, opiates, benzodiazepines, synthetic cannabinoids, amphetamines, and cathinones. The samples were loaded onto ISOLUTE® Multimode sorbent in cartridge format. Sample extraction methodologies for urine and whole blood were developed with optimized wash steps to maximize cleanliness and minimize observed ion suppression. The drugs were extracted in a two-step process to elute the acidic and neutrals and then the basic analytes. The samples were dried down, reconstituted, and analyzed using an Applied Biosystems® 4000 QTRAP® with an Agilent 1200 liquid chromatographic system.

Results: A preliminary suite of drugs was tested on silica-based mixed-mode SPE sorbents. The drugs tested were opiates and benzodiazepines fortified in urine at 10ng/mL concentrations. A total of 14 replicate samples were run. The observed averaged recoveries for the benzodiazepines ranged from 50%-101% with intra-run %RSDs less than 10% for the analytes in urine. The observed averaged recoveries for the opiates ranged from 78%-110% with intra-run %RSDs less than 10% in urine.

Conclusion: A full screening method for the extraction of a broad panel of drugs with good recoveries is presented.

Sample Preparation, Drugs of Abuse, LC/MS

K23 Adulterants and Diluents in Urine Samples After Consumption of Cocaine: What Compounds Are Typically Found by Liquid Chromatography (LC) Combined With High-Resolution Tandem Mass Spectrometry (HRMS/MS)?

Werner Bernhard, DSc*, IRM University of Bern, Buehlstrasse 20, Bern, CH-3012, SWITZERLAND; Stefan Koenig, PhD, Institute of Forensic Medicine, Buehlstrasse 20, Bern 3012, SWITZERLAND; Franziska Penitschka, BSc, Institute of Forensic Medicine, Buehlstrasse 20, Bern 3012, SWITZERLAND; Lars Ambach, MSc, Institute of Forensic Medicine Bern, Buehlstrasse 20, Bern 3012, SWITZERLAND; Susanne Nussbaumer, PhD, Institute of Forensic Medicine, Buehlstrasse 20, Bern 3012, SWITZERLAND; and Wolfgang Weinmann, PhD, Institute of Forensic Medicine, Buehlstrasse 20, Bern 3012, SWITZERLAND

After attending this presentation, attendees will understand that in forensic urine samples which test positive for cocaine, in addition to metabolites of cocaine, pharmacologically active compounds are usually found. These compounds were added as adulterants to the illicit street drug. Acquisition of mass spectra in SWATH® mode on a Quadropole Time-of-Flight (QqToF) instrument allows retrospective searches for adulterants and their metabolites.

This presentation will impact the forensic science community by presenting a rapid and reliable analytical method to detect potentially toxic and hazardous adulterants in urine samples. Since this additional forensic toxicological information can be routinely collected, it can be helpful in expanding police intelligence.

Goals: Cocaine consumption is observed as a wide-spread phenomenon and in most cases the cocaine abusers also consume a considerable amount of adulterants, diluents, or even toxic contaminants without being aware of possible side effects, long-term adverse health effects, or acute toxicity.

In order to assess the exposure of cocaine users to such substances, an High-Performance Liquid Chromatography/Quadropole Time-of-Flight (HPLC/QqToF) method for urine samples was developed.

Methods: Urine samples were diluted with a mixture of water/acetonitrile/formic acid/ammonium formate (97.5/2.5/0.1%/5.0mM) and three internal standards were added (EME-D₃, Tramadol-¹³C₃, THC-D₃). The diluted samples were injected onto a core shell column (C8, 50 x 2.1mm, 2.6µm) and analyzed on a QqToF instrument with typical run times of 15 minutes from injection to injection.

Results: In the past two years, more than 4,000 urine samples (coming from traffic controls or traffic accidents) were analyzed by LC combined with HRMS/MS and then processed against a home-built high-resolution library. This library currently contains approximately 1,000 spectra which are relevant for drug screening and also includes most of the currently observed adulterants, diluents, and contaminants. All spectra were acquired by the data independent scan mode (sequential windowed acquisition of all theoretical mass spectra) which generates a digital archive of each acquired sample. The scan parameters were optimized in order to meet the complexity of these urine samples. The following parameters were found to be most favorable for significant library hits: scan range from 50 to 950 Da, scan windows of 25 Da, scan time of 35 msec for each scan window, and collision energy of 35eV±15eV (collision energy spread).

In most of the acquired samples, if tested positive for cocaine or its metabolites, adulterants and diluents can be observed. Among the typical compounds are levamisole, phenacetin, lidocaine, and procaine. In some cases, diltiazem and benzocaine were found. Acquisition of mass spectra in sequential windowed acquisition of all theoretical mass spectra mode also allows retrospective searches for additional compounds. During the same period as the urine samples were screened, 684 cocaine hydrochloride samples were analyzed with High-Performance Liquid Chromatography/Diode Array Detection (HPLC-DAD). The following adulterants were found: Levamisole+Phenacetin+others (30%), Levamisole+Phenacetin (26.3%), Levamisole only (20.0%), Levamisole+others (10.4%), Phenacetin+others (5.1%), others only (3.2%), Phenacetin only (2.9%), and none (2.0%).

Conclusions: A fast and reliable analysis of urine samples for adulterants commonly found in cocaine was developed. Results from urine samples obtained with the new method confirm the results from the analysis of cocaine powder samples. The analysis of the illicit cocaine hydrochloride samples indicate that the vast majority of the cocaine contains pharmaceutically active adulterants. These adulterants are an additional health hazard for cocaine consumers.

High Resolution Tandem MS, Cocaine, Adulterants

K24 Impact of Novel Accurate Mass MS/MSALL Acquisition and Processing Techniques on Forensic Toxicological Screening

Adrian M. Taylor, MSc, PhD, 71 Four Valley Drive, Concord, ON L4K 4V8, CANADA*

After attending this presentation, attendees will be better informed about a novel data-independent mass spectrometric technique that allows Tandem Mass Spectrometry (MS/MS) of All possible candidates (MS/MSALL) and provides significant improvements in identification. Attendees will be aware of the ability to retrospectively analyze the data for compounds that were not originally targeted. This presentation will describe how powerful a technique rapid forensic toxicology screening by high-resolution mass spectrometry is, while showing that some compounds cannot be unambiguously identified with high-resolution MS measurements alone.

This presentation will impact the forensic science community by illustrating that data-independent techniques, such as SWATH™ acquisition (the MS/MS of all possible candidates), significantly improve identifications and enable retrospective analysis of the data.

Introduction: MS/MS fragmentation yields confident identifications of these compounds, but how to ensure quality MS/MS of these compounds? Data dependent techniques, although very powerful, cannot guarantee the measurement of all possible MS/MS candidates. Targeted MS/MS ensures acquisition of the target compounds, but limits the number of compounds.

Objectives: To evaluate the impact of improvements to SWATH™ acquisition, including variable precursor window sizes, overlapping windows, and deconvolution of MS/MS from multiple precursors.

Methods: Urine was spiked with more than 120 drugs and compounds often found in forensics screening panels. The data was collected on a Triple TOF® 5600 system using one of the following methods: (1) a TOF/MS survey scan with Information Dependent Acquisition (IDA) -triggering of up to 20 product ion scans; or, (2) SWATH™ acquisition. For SWATH™ acquisition, the precursor isolation window width was varied for each MS/MS experiment, or the windows were overlapped between each cycle. Data was processed in PeakView® software 2.0, using a research prototype of MasterView™ software.

Results: Astemizole and amlodipine both demonstrated the advantage of having narrower SWATH™ isolation windows. The overlap 20 Da SWATH™ window acquisition (after demultiplexing was performed) resulted in MS/MS that were significantly reduced in interferences. The library match purity scores were improved from 2.2% to 97.5% and 38.8% to 92.7%, respectively. Having narrower isolation windows improves the specificity of MS/MS data, but at a cost. Either accumulation times must be decreased (which would make signal to noise worse) or cycle times will get longer (reducing the number of points across a peak). It is shown with the example of berberine that using overlap SWATH™ acquisition that the demultiplexed MS/MS can approach the quality of a true 10 Da SWATH™ acquisition MS/MS, while having an improved cycle time. Deconvolution of SWATH™ MS/MS was also shown to improve library match purity scores. Unprocessed SWATH™ MS/MS had significantly lower purity scores for many compounds. Simple background subtraction resulted in MS/MS of much better quality. Two other deconvolution techniques were tried. Method A was similar to techniques used for deconvolving Gas Chromatography/Mass Spectrometry (GC/MS) signals, and was implemented to run on an NVIDIA 660 graphics card. Method B is a novel technique making use of Principal Components Variable Grouping (PCVG) to obtain a SWATH™ MS/MS. When the techniques were combined, results were equivalent to those achieved using unit resolution IDA. For a few compounds, IDA was not triggered, resulting in no identification. While the SWATH™ acquisition was able to confidently identify these compounds with good purity scores.

Conclusion: SWATH™ acquisition methods acquire MS/MS for all compounds, at every time point, achieve identification results comparable to unit resolution IDA methods and overlap SWATH™ acquisition can improve cycle times and improve identification results.

Unknown Screening, Data Independent Acquisition, Comprehensive Analyte Coverage

K25 Analysis of Acetyl Fentanyl in Postmortem Blood and Urine Specimens by Gas Chromatography/Mass Spectrometry (GC/MS)

Marissa J. Finkelstein, BA*, University of Florida, College of Medicine, 4800 SW 35th Drive, Gainesville, FL 32608; Chris W. Chronister, PhD, University of Florida, Pathology Labs, 4800 SW 35th Drive, Gainesville, FL 32608; Christina Stanley, MD, Rhode Island Office of State ME, 50 Orms Street, Providence, RI 02904; Laurie M. Ogilvie, MS, RI Dept of Health/Labs, 50 Orms Street, Providence, RI 02904; and Bruce A. Goldberger, PhD, University of Florida College of Medicine, Dept of Pathology, 4800 SW 35th Drive, Gainesville, FL 32608

After attending this presentation, attendees will better understand the quantitation of acetyl fentanyl in biological specimens utilizing Solid Phase Extraction (SPE) and GC/MS. In addition, attendees will better understand the postmortem distribution of acetyl fentanyl.

This presentation will impact the forensic science community by providing the first reported analytical method for the quantitative analysis of acetyl fentanyl in postmortem blood and urine specimens.

In 2013, the Centers for Disease Control and Prevention issued an alert regarding a new illicit drug, acetyl fentanyl. Acetyl fentanyl was implicated in the death of 15 decedents in Rhode Island from March 2013 through December 2013.¹ Acetyl fentanyl is an analog of fentanyl, and its pharmacological effects include altered mood, euphoria, respiratory depression, and central nervous system depression. Acetyl fentanyl is a μ -opioid receptor agonist with potency reportedly 15 times greater than morphine, but one-third the potency of fentanyl, based on animal studies.²

Due to the novelty of the analyte, it was important to develop a sensitive and specific method for the extraction of acetyl fentanyl from postmortem specimens. This study followed method validation procedures published by the Scientific Working Group for Forensic Toxicology (SWGTOX) to develop and validate a method to quantify acetyl fentanyl in postmortem blood and urine.

SPE (SPEware CEREX Trace -B) was utilized to isolate acetyl fentanyl from the biological matrices. A 1.0mL sample of blood and urine was aliquoted and fortified with isotope-labeled internal standard solution containing $^{13}\text{C}_6$ -acetylfentanyl. The samples were buffered with pH 6.0, 0.1M phosphate buffer, vortexed, and centrifuged. The samples were transferred to preconditioned SPE columns. The columns were sequentially washed with deionized water, 100mM acetic acid, methanol, and dried for five minutes under N_2 . The analytes were eluted with a 78:20:2 (v:v:v) methylene chloride:isopropanol:ammonium hydroxide elution solvent. The eluents were dried at 37°C under N_2 , reconstituted with ethyl acetate, and submitted for GC/MS analysis.

The GC/MS parameters included splitless injection with an initial temperature of 140°C, hold for 0.5 minutes, ramp at 30°C/minute to the final temperature of 320°C with a final hold time of seven minutes. The total run time was 13.5 minutes. The helium flow rate was 1mL/minute. GC/MS analysis was conducted in Selected Ion Monitoring (SIM) mode utilizing the following ions: acetyl fentanyl, m/z 231, 188, 146 and $^{13}\text{C}_6$ -acetyl fentanyl, m/z 237, 194, 152. The assay was linear from 1.0ng/mL to 50ng/mL. The lower limit of quantitation was defined as the lowest non-zero calibrator, 1.0ng/mL, and the experimental limit of detection was 0.5ng/mL and 0.75ng/mL in blood and urine, respectively.

Specimens were obtained from the Rhode Island Office of State Medical Examiners and University of Florida Health Pathology Laboratories — Forensic Toxicology Laboratory for the analysis of acetyl fentanyl. The deaths occurred from March to December 2013. Acetyl fentanyl was detected in 14 decedents: nine males and five females, aged 23-57 years old. The results of the acetyl fentanyl analyses are shown in Table 1. According to the results indicated, acetyl fentanyl demonstrates postmortem redistribution with heart-to-femoral blood concentration ratios ranging from 0.97-2.84, with a mean of 1.59 in a group of eight fatalities.

Table 1. Acetyl fentanyl concentrations from casework.

	Femoral Blood (ng/mL)	Heart Blood (ng/mL)	Antemortem Blood (ng/mL)	Postmortem Urine (ng/mL)	Ratio of Heart-to-Femoral Blood Concentration
Mean	338.6	386.7	136.6	3705.3	1.59
Range	89-945	17-915	57-178	41-9825	0.97-2.84

Toxicology Section - 2015

SPE followed by GC/MS analysis was shown to be an acceptable method for the quantitation of acetyl fentanyl in postmortem blood and urine specimens, and the assay provided a sensitive and specific method while limiting interferences typically found in postmortem blood and urine.

Acetyl Fentanyl, Method Validation, GC/MS

K26 Postmortem Distribution of Acetyl Fentanyl

Xiang Zhang, MD*, OCME, 900 W Baltimore Street, Baltimore, MD 21223; Rebecca Jufer Phipps, PhD, State of MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223; Barry S. Levine, PhD, OCME, 900 W Baltimore Street, Baltimore, MD 21223; Patricia Aronica, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223; James Locke, 900 W Baltimore Street, Baltimore, MD 21223; Melissa A. Brassell, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223; Wendy S. Warren, DO, Armed Forces Medical Examiner System, 115 Purple Heart Drive, Dover AFB, DE 19902; Mary G. Ripple, MD, 900 W Baltimore Street, Baltimore, MD 21223; and David R. Fowler, MD, OCME, 900 W Baltimore Street, Baltimore, MD 21223

After attending this presentation, attendees will have a better understanding of the analysis of biological specimens for acetyl fentanyl and the postmortem distribution of acetyl fentanyl.

This presentation will impact the forensic science community by providing medical examiners and toxicologists with an analytical method and postmortem concentrations for acetyl fentanyl, a relatively new drug of abuse in the United States.

Acetyl fentanyl (*N*-(1-phenethylpiperidin-4-yl)-*N*-phenylacetamide) is a potent synthetic opioid with structural similarity to fentanyl. Animal studies have estimated acetyl fentanyl to be about one-third as potent as fentanyl.¹ Acetyl fentanyl has recently gained public attention when it was linked to 12 fatal overdoses in Rhode Island.²

The Office of the chief Medical Examiner of the State of Maryland has investigated three deaths related to acetyl fentanyl use. The cause and manner of death was acetyl fentanyl intoxication/undetermined for each of the three following cases.

Case 1: A 23-year-old White male college student was found unresponsive on his bedroom floor. He had attended a banquet the night before, visited a few bars, then returned home where he watched television with a friend for several hours before going to bed. The friend found him later the next day and he was pronounced deceased at the scene. The decedent's bedroom contained pills, powders, and drug paraphernalia. It was reported that the decedent had a history of drug abuse and had been in rehab approximately one year prior.

Case 2: A 36-year-old African American male was found lying on the floor with vomit and blood on the carpet next to him. He was reportedly visiting with friends and had used cocaine with them. It was also reported that he may have used heroin. He was transported to the hospital where resuscitation attempts were unsuccessful. The decedent did have prior arrests for possession of a controlled substance.

Case 3: A 17-year-old Hispanic male was at a friend's house. He was reportedly offered a powder that another individual was snorting. Soon after, the decedent became unresponsive. Treatment with Narcan™ and resuscitative efforts were unsuccessful.

Acetyl fentanyl was identified in an alkaline drug screen, which involved an alkaline extraction of specimens followed by detection with Gas Chromatography/Nitrogen Phosphorous Detection (GC/NPD) and confirmation by Gas Chromatography/Mass Spectrometry (GC/MS). Acetyl fentanyl elutes shortly before fentanyl on an HP-5 column and prominent GC/MS ions are 231, 146, and 188. Further evaluation of the standard liquid-liquid alkaline extraction screening procedure in use in the laboratory indicated adequate sensitivity for the detection of acetyl fentanyl, which was detected at concentrations less than 5ng/mL. Subsequently, a quantitation method was developed for acetyl fentanyl. Briefly, internal standard (d5-fentanyl) was added to specimens which were alkalized and extracted with n-butyl chloride:ether then back extracted into sulfuric acid and finally alkalized and extracted into methylene chloride, evaporated and reconstituted with methanol. The extract was injected into the GC/MS which was operated in the selected ion monitoring mode. The ions monitored included 231, 146, 188 (acetyl fentanyl) and 250, and 194 (d5-fentanyl). The method was linear from 25ng/mL to 800ng/mL. Case specimens with concentrations above 800ng/mL were diluted with distilled water to ensure the results were within the calibration curve. The results (ng/mL or ng/g) are summarized below.

Case	Heart Blood	Femoral Blood	Liver	Kidney	Urine	Vitreous Humor	Additional Toxicology Findings
1	700	460	1800	1200	1600	500	Urine: alpha-pyrrolidinovalerophenone positive
2	180	180	180	250	380	160	Blood Benzoylcegonine 1.3 mg/L
3	500	430	430	220	1500	350	None

Toxicology Section - 2015

Acetyl fentanyl was detected at much higher concentrations relative to what is typically seen for fentanyl intoxications, which is consistent with its lower potency relative to fentanyl. Although there were some differences between heart blood and femoral blood concentrations, the greatest difference was seen in the case with the highest concentration, and the heart blood concentration was within 35% of the femoral blood concentration. The liver and vitreous humor concentrations were close to the blood concentrations. Urine also contained a higher concentration of acetyl fentanyl relative to blood, making it a suitable specimen to screen for acetyl fentanyl use.

Kraner, PhD, OCME, 619 Virginia Street, W, Charleston, WV 25302*

After attending this presentation, attendees will better understand the postmortem toxicology investigation involving the recreational use of acetyl fentanyl, one of a new group of psychoactive compounds being recreationally abused in the United States.

This presentation will impact the forensic science community by providing useful information pertaining to acetyl fentanyl, an opioid drug rarely encountered in forensic casework.

Among the new psychoactive substances encountered in forensic investigations in the United States is the anilidopiperidine class opioid, acetyl fentanyl. Abuse of this compound has resulted in more than 50 fatalities in the United States since 2013.

A 28-year-old male was found unresponsive on the bathroom floor at a residence he shared with a roommate, who had last known him to be alive approximately 12 hours earlier. A tourniquet fashioned from a belt was secured around his arm and a syringe was found nearby. The decedent, who had a history of substance abuse, including the use of anabolic steroids, was pronounced dead at the scene. External examination revealed needle track marks along the inside of the arm and foamy secretions at the mouth. Autopsy revealed marked pulmonary edema and mild diffuse cerebral edema, with no contributory natural disease or physical injury identified.

Immunoassay of urine for a panel of drugs of abuse gave a positive presumptive result for fentanyl alone. The presence of acetyl fentanyl was confirmed through Gas Chromatography/Mass Spectrometry (GC/MS) analysis of urine and Liquid Chromatography/Time-of-Flight/Mass Spectrometry (LC/TOF/MS) analysis of subclavian blood. Acetyl norfentanyl and its putative metabolite N-phenyl-1-(2-phenylethyl)piperidin-4-amine were detected in the blood, liver, and urine. An existing Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) procedure for fentanyl and norfentanyl confirmation and quantitation was modified in order to determine acetyl fentanyl in autopsy blood, urine, vitreous fluid, and liver. LC was performed using a Waters® ACQUITY® Ultra-Performance Liquid Chromatograph (UPLC); and tandem MS analysis was performed using a Waters® TQ-D detector with ionization in electrospray positive mode. Method validation consisted of examining bias, calibration model, carryover, and matrix effects. Acetyl fentanyl was detected in subclavian blood, liver, vitreous fluid, and urine at concentrations of 235ng/mL, 59.6ng/gm, 131ng/mL, and 234ng/mL, respectively. Tadalafil was present at 79ng/mL. Urine was analyzed for a panel of anabolic steroids revealing the presence of testosterone at 34.7ng/mL and epitestosterone at 2.5ng/mL, with oxandrolone also present in the urine. Acetyl fentanyl was detected by GC/MS analysis in a methanolic rinse of a syringe found at the scene.

Currently, limited information indicates that acetyl fentanyl acts as a mu-opioid receptor agonist with potency less than that of fentanyl, but greater than morphine. Taking into consideration of comparable average acetyl fentanyl blood concentration of 213ng/mL in three other forensic cases evaluated by a private forensic toxicology laboratory, the cause of death in this case report was determined to be acetyl fentanyl intoxication and the manner was deemed to be accidental.

Along with meager recent reports addressing a host of emerging novel opioid analogs, this case underscores the need for awareness and consideration of the potential involvement of such drugs when investigating apparent recreational drug-related deaths.

Forensic Toxicology, Acetyl Fentanyl, Postmortem

K28 Trazodone and M-Chlorophenylpiperazine (m-CPP) Concentrations in Postmortem Blood

*C. Richard Crooks, PhD**, Aegis Sciences Corporation, 365 Great Circle Road, Nashville, TN 37228; *David M. Schwope, PhD*, Aegis Sciences Corporation, 365 Great Circle Road, Nashville, TN 37228; and *Jana A. James, MS*, 209 Hatfield Drive, Franklin, TN 37064

After attending this presentation, attendees will be able to describe expected concentrations of trazodone and m-CPP, a metabolite of trazodone, in postmortem blood.

This presentation will impact the forensic science community by providing data that will assist forensic toxicologists in interpreting trazodone and m-CPP concentrations in postmortem casework.

Introduction: Trazodone has been used as an antidepressant for more than 30 years. Structurally, it is unique and unrelated to the tricyclic and tetracyclic antidepressants, as well as the newer SSRI and SNRI antidepressants. m-CPP is the major metabolite of trazodone; but is also considered a “designer” drug that can be abused by itself. Although postmortem trazodone blood concentrations have been documented, reports of postmortem m-CPP concentrations in blood are lacking.

Method: This study is a compilation of data obtained from 30 cases over a five-month period (femoral or heart blood). Trazodone samples were prepared by analysis using a dual Liquid-Liquid Extraction (LLE). Prior to extraction, each specimen was fortified with internal standards and pH adjusted using ammonium hydroxide. Solvent was evaporated to dryness and reconstituted in 150 μ L 10mM ammonium acetate, 0.1% formic acid High-Performance Liquid Chromatography (HPLC) water (mobile phase). Samples were analyzed via a Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) instrument comprised of a Shimadzu[®] HPLC and ABSciex[™] API 3200 tandem mass spectrometer. Ionization was attained by electrospray (positive mode) with Multiple Reaction Monitoring (MRM) mode employed for detection and quantification. Gradient chromatographic separation starting at 20% B (0.1% formic acid in acetonitrile) was achieved using a C₁₈ column (100 x 2.1mm, 3 μ m particle). Flow rate was 0.7mL/min with an overall run time of 3.0 minutes. Conservative Limits Of Quantification (LOQ) were 20ng/mL for both analytes. The assay was validated for linearity from 5ng/mL-250ng/mL trazodone and m-CPP ($r^2 > 0.980$ and concentrations within $\pm 20\%$ of target). Precision was characterized by CVs of 4.2% and 3.0% for trazodone and m-CPP, respectively, at 250ng/mL, and 6.3% and 7.9% at 20ng/mL. Accuracy was characterized by deviations of -3.2% and -3.0% for trazodone and m-CPP, respectively, at 250ng/mL, and 5.2% and -1.0% at 20ng/mL. No quantifiable carryover was observed at the method Upper Limit Of Quantification (ULOQ).

Results: Of 19 femoral blood specimens containing trazodone at >20 ng/mL, m-CPP was not detected in five specimens (LOD 5ng/mL), detected at $>$ LOD but <20 ng/mL in six specimens, and quantified at >20 ng/mL in eight specimens (trazodone mean of 596ng/mL, range 225ng/mL-1,383ng/mL, and m-CPP mean of 36.0ng/mL, range 21.4ng/mL-69.5ng/mL). Of 11 heart blood specimens containing trazodone at >20 ng/mL, m-CPP was not detected in three specimens (LOD 5ng/mL), detected at $>$ LOD but <20 ng/mL in two specimens, and quantified at >20 ng/mL in six specimens (trazodone mean of 836ng/mL, range 188ng/mL-2,145ng/mL, and m-CPP mean of 90.4ng/mL, range 26.6ng/mL-125ng/mL).

Conclusions: Trazodone and m-CPP concentrations are presented from 30 postmortem cases obtained over a six-month period. Trazodone concentrations were similar to literature values, with m-CPP detected $>$ LOD in 22 of 30 cases. This data set will assist forensic toxicologists in casework where trazodone or m-CPP intake has occurred.

Trazodone, m-CPP, Postmortem Blood

K29 A Case of Suicide Using Veterinary Drug T-61® With Subsequent Submergence in the Sea

*Claudia Trignano**, *viale italia 14, Sassari, ITALY*; *Maria Nieddu, BS, University of Sassari, Dept of Chemistry and Pharmacy, Sassari, ITALY*; *Antonio Nieddu, MD, Sassari, Sassari, ITALY*; *Santina Cantatore, Viale degli Aviatori 1, Foggia 71100, ITALY*; *Stefania C. Bello, MD, Ospedale Colonnello D'Avanzo, viale degli Aviatori, Foggia 71100, ITALY*; and *Margherita Neri, MD, PhD, University of Foggia, Dept Forensic Pathology, Viale degli Aviatori 1, Foggia 71100, ITALY*

After attending this presentation, attendees will understand the suicide case of a man who used Tanax® (T-61®), a drug used for euthanasia in veterinary practices, with subsequent submergence in water.

This presentation will impact the forensic science community by presenting the results of the postmortem examination which showed elements that excluded drowning as cause of death. Instead, histological findings, autopsy evidence, and toxicological analysis (a high level of embutramide and mebezonium iodide in the blood) resulted in the conclusion that death was a result of Tanax® injection.

The present case concerns an acute fatality resulting from self-administration of Tana® (T-61®) in a 35-year-old man, who was found near water and at a first look, appeared like an accidental drowning.

T-61®, consisting of a mixture of embutramide, mebezonium, and tetracaine, is a pharmaceutical used for euthanasia of animals because of its narcotic and muscle relaxant (curariformlike) activity. Embutramide is a general anesthetic that possesses a strong narcotic effect that rapidly induces deep anesthesia. Mebezonium iodide is a quaternary ammonium that paralyzes the skeletal muscles, resulting in a respiratory collapse. Finally, tetracaine, a local anesthetic, is used to reduce painful tissue reactions at the injection site.

A man was found dead near the sea wearing underpants, socks, shoes, and a backpack full of stones; beside his clothes four apparently empty used syringes and a bottle were found. He worked in a drug warehouse, had no known mental disorder, and seemed to be in good health.

The prosecutor arranged for an autopsy on the body to clear up the circumstances of his death and distinguish between homicide and suicide by drowning. A complete autopsy was performed 24 hours after death.

At the external examination, the man showed peculiar lesions on both inner arms, two needle puncture marks, and a remarkable cyanosis of the face, lips, and nails.

All internal organs were congested. The pleural cavities contained 12cc of yellowish fluid. The lungs were edematous with areas of hemorrhage mainly seen on the right side. The pericardial cavity contained 2cc of yellowish fluid. The heart showed few epicardial petechia. The abdominal cavity contained 15cc of yellowish fluid. The stomach was empty. The liver was congested and had steatotic appearance on cut sections. Other organs were unremarkable except of edema. Histopathologic examination showed wide foci of early contraction band necrosis in heart samples. The lungs presented alveolar septa mildly thickened by edema and capillary congestion, alveolar edema. Steatosis was confirmed in the liver. The kidneys presented air bubbles in glomerular capillaries and immunohistochemistry performed with antibody anti-CD 61 and fibrinogen showed a vital reaction, platelet aggregates (anti CD 61 antibody) at the edge of air globules and an adsorbed fibrinogen (anti-fibrinogen antibody) layer to the interface of air globules. In addition, the immunohistochemical study was completed using antibody anti-heat shock proteins researching the renal tissue heat shock proteins (HSP 70, 27, 90) which are a group of proteins that are rapidly induced in response to physiological stress, including hyperthermia, infections, tumors, ischemic stimuli, and exposure to toxicants. The reaction revealed a strong positivity for HSP 27, an intermediate positive reaction for HSP 70, and a mild positivity for HSP 90. During the autopsy, femoral blood and urine were collected for toxicological analysis.

Embutramide and mebezonium iodide were found in both biological matrices using a direct and sensitive liquid chromatography/tandem mass spectrometry method for the simultaneous determination of the two drugs. Lidocaine was used as an internal standard. Limits of detection and quantitation were 0.01mg/L and 0.05mg/L, respectively, for both compounds.

Embutramide concentrations in blood and urine were 10.1mg/L and 0.40mg/L, respectively. The mebezonium iodide concentration was 0.65mg/L in blood and 0.07mg/L in urine. The chromatographic method was additionally optimized for determination of diazepam; diazepam was found in both samples (0.015mg/L in blood and traces in urine). The blood sample collected during the postmortem examination was tested by gas chromatography for detection of ethanol which was found at a concentration of 0.40g/L.

Toxicology Section - 2015

The urine was further examined for amphetamine and related compounds, cannabinoids, methadone, opiates, cocaine, and its metabolites, all with negative results.

Tanax® (T-61®) Injection, Suicide, Drowning

K30 Development and Validation of a Method Using Gas Chromatography/Mass Spectrometry (GC/MS) After Liquid-Liquid Extraction (LLE) for the Detection and Quantification of Clotiapine in Blood and Urine and Its Application to a Postmortem Case

Giulio Mannocchi*, Sapienza University Of Rome, S.a.i.m.l.a.l., 336, Viale Regina Elena, Rome 00161, ITALY; Flaminia Pantano*, Sapienza University Of Rome, S.a.i.m.l.a.l., 336, Viale Regina Elena, Rome 00161, ITALY; Roberta Tittarelli, Sapienza University Of Rome, S.a.i.m.l.a.l., 336, Viale Regina Elena, Rome 00161, ITALY; Miriam Catanese, Sapienza University Of Rome, S.a.i.m.l.a.l., 336, Viale Regina Elena, Rome 00161, ITALY; Federica Umami Ronchi, Sapienza University Of Rome, S.a.i.m.l.a.l., 336, Viale Regina Elena, Rome 00161, ITALY; and Francesco P. Busardo, MD, via del vespro, 129, Palermo, ITALY

The goal of this presentation is to inform attendees of possibly fatal complications due to clotiapine intake by considering the autopsy results and the toxicological findings, including substance concentration and distribution in biological samples.

This presentation will impact the forensic science community by providing a reliable method for the detection and quantification of clotiapine in blood and urine samples by means of GC/MS after LLE.

Introduction and Goals: Clotiapine is an atypical antipsychotic of the dibenzothiazepine chemical class. It was first introduced in a few European countries in 1970. Despite the high incidence of extrapyramidal side effects, it has demonstrated efficacy in treatment-resistant schizophrenic patients.

Here, a method for the detection and quantification of clotiapine in blood and urine samples by GC/MS after LLE has been developed and fully validated. The method has been applied to a fatal case involving a 45-year-old man found dead in his private apartment.

Methods: For the extraction, blood, urine, and gastric contents were extracted according to the following procedures: to 1mL of each liquid sample were added 1mL of deionized water and 500ng of methadone-d9 as internal standard. Samples were extracted at pH 8-8.5 (50mg of solid $\text{HCO}_3^-/\text{CO}_3^{2-}$ -buffer added) with 4mL of extraction solution (n-hexane/dichloromethane (85/15v/v) for 15min. After centrifugation (4,000 rpm, 3min) the organic layer was evaporated to dryness under nitrogen flow. The residue was reconstituted with 50 μ L of ethyl acetate.

GC analysis was carried out on an Agilent® HP 7028A GC coupled with an Agilent® MSD 5975. The capillary column used was an HP-5MS (17m x 0.25mm I.D. coated with a 0.25 μ m film). The GC conditions were as follows: the column temperature was programmed from 120°C to 290°C with an increase of 10°C/min; the injection port and the transfer line temperature was 270°C; helium was used as carrier gas with flow rate of 1mL/min; the split injection mode had a ratio of 15:1. The mass analyzer operated by electron impact (-70eV) in the Selected Ion Monitoring (SIM) mode. Quantitative analysis was carried out recording ions m/z 209-244-343 for clotiapine and m/z 78-165-303 for methadone-d9. The underlined ions were used for quantitative analysis.¹

Application to a Postmortem Case: A 45-year-old man died in bed in his private apartment. Relatives could offer very little information about the circumstances of death, but positive information about mental illness (schizophrenia) was reported. The autopsy showed the presence of bladder over-distension due to massive urinary retention and contained 3.7L of urine. All other organs were unremarkable, with only a moderate pulmonary edema being found. The toxicological analysis, using the method developed above and validated showed the following concentrations: 1,318ng/mL in peripheral blood, 487ng/mL in urine (the clotiapine concentrations in urine samples were creatinine-normalized) and 1,860ng/mL in the gastric contents. No other drugs nor alcohol were detected in the biological samples.

Conclusions: A reliable method for the detection and quantification of clotiapine in blood and urine samples has been developed and validated. The application of the method to the reported case allowed identification of clotiapine at very high concentrations in blood, urine, and gastric contents, although there is little evidence in literature about its toxic values. In this case, the cause of death, taking into consideration the autopsy and toxicological findings, was due to a post-renal failure due to a severe bladder over-distention induced by clotiapine.

K31 Pesticide Poisoning Deaths in Istanbul and Nearby Cities in Turkey

*Erdoğan Özdemir**, The Council of Forensic Medicine, Ministry of Justice. Çobançeşme Mah., Kimiz Sok.no:1 Bahçelievler, Istanbul, TURKEY; *Yigit Sezer*, Bahçelievler Mah Yıldızli Sok 5/10, Istanbul, TURKEY; *Yusuf Özer*, Council of Forensic Medicine of Istanbul, Ministry of Justice, Istanbul, TURKEY; *Safa Celik*, Adli Tip Kurumu Baskanligi, Istanbul, TURKEY; and *Sermet Koc*, Adli Tip Kurumu Morg Dairesi Baskanligi, Bahcelievler, Istanbul 34196, TURKEY

After attending this presentation, attendees will better understand pesticide poisoning, its impact, prevention, and the concerns about safety parameters.

This presentation will impact the forensic science community by providing results from a seven-year retrospective study in the vicinity of Istanbul, Turkey. This presentation will add to research being conducted by forensic medicine, forensic toxicology, and public health organizations by contributing to the understanding of the proper usage of pesticides in agriculture and the different methods of consumption for other purposes, either accidental or suicidal.

Although some kinds of agricultural pesticides are strictly banned in developed countries, they are easily found in local markets and pharmacies in most of the developing countries. Despite the high amount of consumption ratios of the developed countries, pesticide poisoning rates are higher in developing and underdeveloped countries. Despite the regional studies, extensive and comprehensive data about the manners of pesticide poisoning in Turkey are still lacking.

Pesticides are chemicals that are used to reduce the deleterious effects of various species such as insects, rodents, weeds, and fungi which cause the qualitative and quantitative loss of agricultural products during the production, storage, and consumption processes. Pesticides are categorized as fungicide, herbicide, rodenticide, repellent, or insecticide. Mechanism of action varies according to the type of the pesticide. Effects of irresponsible and uncontrolled consumption of pesticides to human health and the environment are also important issues and should not be ignored. Poisoning is generally encountered accidentally during agricultural usage or as a result of suicidal and homicidal exposure.

In the present study, 29,438 forensic autopsy cases performed in the mortuary department of the Council of Forensic Medicine, Turkey, from 2007 to 2013 were evaluated retrospectively for pesticide poisoning cases. Thirty-four pesticide poisoning cases were determined and studied for a detailed epidemiological and medicolegal analysis. Of these cases, 73.5% were male and 26.5% were female. The mean age of the cases was 42.5 years. Most of the cases (59%) were reported from Istanbul. The most common pesticide encountered was dichlorvos (DDVP) (29.4%), followed by endosulphan (8.8%).

Pesticide poisoning-related deaths are still an important public health issue in society. All safety regulation measures must be taken by all related authorities integratively in the prevention of the deleterious effects of irresponsible consumption of pesticides in agriculture and deliberate poisonings. Further study is needed to arrive at more detailed and comprehensive results of pesticide poisoning data from all regions of Turkey to understand pesticide poisoning in its entirety.

Pesticide, Poisoning, Epidemiology

K32 The Role of Cytochrome P450 2B6 (CYP2B6) Genetic Polymorphisms in Unexpected Methadone Fatalities

Taha Ahmad, MSFS, 180 Mallory Avenue, Jersey City, NJ 07304; Samie Sabet, Marshall University School of Medicine, One John Marshall Drive, Huntington, WV 25755; Lauren L. Richards-Waugh, PhD, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; and Gary O. Rankin, PhD, Marshall University School of Medicine, One John Marshall Drive, Huntington, WV 25755*

After attending this presentation, attendees will understand the potential role of cytochrome P450 2B6 (CYP2B6) genetic polymorphisms in methadone metabolism and overdose. CYP2B6 is one of the key enzymes involved in the metabolism of methadone. The research presented explores the association of specific Single Nucleotide Polymorphisms (SNPs) in the CYP2B6 gene to methadone metabolism and whether the presence of such SNPs increases the likelihood of fatal methadone intoxication in the Caucasian population. This research may provide insight as to why some individuals succumb to methadone intoxication.

This presentation will impact the forensic science community by serving as a key aspect for the development of genetic testing to be used for screening patients placed on methadone therapy. The hypothesis of this study is that one or more SNPs located within the CYP2B6 gene contributes to or is linked to the methadone poor metabolizer phenotype and identifying such individuals before treatment may decrease the number of fatalities due to methadone intoxication.

West Virginia and Kentucky ranked in the top ten states for increases in fatal methadone overdoses in 1999-2005. CYP2B6 plays a significant role in stereo-selective metabolism of (S)-methadone to 2-ethyl-1,5-dimethyl-3,3-diphenylpyrrolidine (EDDP), an inactive methadone metabolite. Elevated (S)-methadone can cause cardiotoxicity by prolonging the QT interval of the heart's electrical cycle. Large inter-individual variability in the pharmacokinetics of methadone causes ambiguity in the relationship between dose, plasma concentrations, and side effects. While other pharmacogenetic studies have been conducted involving methadone-related intoxications, these studies did not include methadone-only cases. Rather, the studies used cases involving mixed drug intoxications and/or had small sample sizes.

The current study examines 228 cases involving fatal methadone intoxications, 136 of which are attributed to methadone alone. A control group of 268 cases without methadone detected was also studied. Genomic DNA was extracted from blood stain cards prepared during autopsies performed at the West Virginia and Kentucky Offices of the Chief Medical Examiner using the QIAamp® DNA Micro DNA Kit following the manufacturer's protocol for dried blood spots with modification for greater DNA concentration. SNP genotyping was achieved using TaqMan® SNP Genotyping kits from Life Technologies™ following the manufacturer's protocols for real-time polymerase chain reaction and allelic discrimination analyses. Allelic and genotypic frequencies were determined for the six SNPs on the CYP2B6 gene (rs2279344, rs3211371, rs3745274, rs4803419, rs8192709, and rs8192719) in the fatalities attributed to methadone intoxication (n=228) and the control (n=268) cases.

The frequency distributions for each of the six SNPs genotyped were in Hardy-Weinberg equilibrium based on a Chi-squared goodness of fit test with two degrees of freedom. The frequency of minor allele carriers was significantly different between the observed genotypic frequencies and general population ($p < 0.05$) for all the SNPs, except rs8192709, in the West Virginia/Kentucky population for all of the methadone overdose cases and the methadone-only overdoses. A Tukey test showed there was a significant difference in the mean blood methadone concentrations (mg/L) between the variants for SNP rs3211371 in the methadone only fatalities ($p=0.003$). This was not observed in the other SNPs genotyped, but there was an apparent enrichment of the minor allele in the methadone cases.

The results of this study indicate that SNP rs3211371 on the CYP2B6 gene is likely linked with a slow-metabolizer phenotype for methadone and may contribute to unexpected methadone fatality. An individual carrying at least one copy of the minor allele for any of the SNPs studied could have a poor methadone-metabolizer phenotype leading to an increased risk of fatal methadone intoxication.

Methadone, Genetic Polymorphisms, CYP2B6

K33 A Case of Suicide Due to Oral Ingestion of Phorate Revealed by Gas Chromatography/Mass Spectrometry (GC/MS): A Contribution to Clarify the Human Toxicokinetic and the Mechanism of Death

Marco Savito, MD, Viale Degli Aviatori 1, Foggia 71121, Italy; Carmela Fiore, MD, Ospedale Colonnello D'Avanzo, Viale degli Aviatori 1, Foggia 71100, ITALY; Palmira Fortarezza, MS, Ospedale Tatarella, Cerignola, ITALY; Angelo Montana, MD, University of Catania, Via Santa Sofia, Catania, ITALY; and Cristoforo Pomara, MD, PhD, University of Foggia, Dept Forensic Path, University of Malta, Dept of Anatomy, Faculty of Med & Surg Biomedical Sci, Foggia, Misida, Malta 71100, ITALY*

The goal of this presentation is to examine a case of suicide by organophosphates (phorate) revealed by GC/MS. The analytical method, the postmortem toxicological concentration of phorate revealed in gastric content, and the modality of death are discussed.

This presentation will impact the forensic science community by informing attendees of the importance of both the analytical method developed and used for quantifying postmortem phorate and of the useful information about the pathological pathway leading to the related death.

Text: Organophosphates (OP) are the most frequently used insecticides worldwide. These compounds are esters, amides, or simple derivatives of phosphoric and thiophosphoric acids and cause 80% of the reported toxic exposures to insecticides. Phorate (phosphorodithioic acid O,O-diethyl S-(ethylthio)methyl ester) is a systemic and contact restricted-use pesticide; it is primarily formulated as granules to be applied at planting in a band or directly to the seed furrow. It is also used as a nematocide.

Phorate has been classified as a Class I, high-risk toxic OP compound with an LD50 of 1.1-3.7mg/kg bw for rats. Due to its severe acute risk for human health, the World Health Organization has classified phorate as a technical product of extreme hazard; however, it is continuously being used in several countries. Its mechanism of action acts like inhibition of acetylcholinesterase activity by phosphorylating the serine hydroxyl group of the substrate binding domain, which results in accumulation of acetylcholine and induces a "cholinergic syndrome" that induces overstimulation of nicotinic, muscarinic, and central acetylcholine receptors, including various Central Nervous System (CNS) effects such as headache, drowsiness, dizziness, confusion, blurred vision, slurred speech, ataxia, coma, convulsions, and blockage of the respiratory center.

Case Report: A case of suicide in a 70-year-old gardener is described; he was found by his daughter finishing a drink with white granular powder mixed with water. She immediately saw him become disoriented and sweaty and alerted emergency health workers, but the man suddenly collapsed. During transport to the emergency department, despite resuscitation attempts, the man died.

Autopsy was performed 48hrs after death. External examination was unremarkable; the autopsy revealed hyperinflated, overexpanded, and ballooned lungs occupying the entire thoracic cavity. The stomach contained 100mL of a brown liquid that was sampled. Other organs showed an intense vascular congestion. The organ specimens were fixed in 10% buffered formalin and embedded in paraffin. Histological examination of samples revealed generalized stasis. In particular, the lungs presented an eosinophilic proteinaceous material and some hemosiderin-laden macrophages in the alveolar cavities, associated with blood congestion of the interstitial vascularization.

The etiopathogenetic definition was outlined by a comprehensive toxicological screening performed on cardiac blood, urine, and gastric contents using a combination of immunoassay and chromatographic techniques. A Liquid-Liquid Extraction (LLE) was performed. At the time of autopsy 1mL of blood, urine, and gastric contents were collected and stored at -20°C. In detail, the LLE was performed for five minutes with cyclohexane, after the organic layer was evaporated until dry under a stream of nitrogen at room temperature. The dry residues were then taken up with 100µL of acetone for the GC/MS analysis. Phorate calibrators of 0.5mg/L, 1mg/L, 2mg/L, and 5mg/L were prepared in blank human blood. Phorate concentration, detected in the gastric contents, was 3.29mcg/mL. No others exogenous substances were found. The complete toxicological results with graphics and tables will be presented.

According to current research, a lethal ingestion of phorate is rarely reported in the literature. Human toxicokinetic data are available but limited. Results related to toxicity and pharmacodynamics data were obtained through animals studies. The acute phorate toxicity due to poisoning can manifest in three different phases: acute cholinergic crisis, Intermediate Syndrome (IMS), and delayed polyneuropathy.

Toxicology Section - 2015

In this case study, according to macroscopic and microscopic findings, the cause of death was most likely respiratory failure and pulmonary dysfunction due to acute cholinergic crisis. In conclusion, this presentation provides useful information about the modality of death and a clear indication of a toxic concentration of phorate detected in gastric contents.

Phorate, Cholinergic Crisis, Toxicological Findings

K34 Heroin-Related Deaths in the West of Scotland Between 2008 and 2011

Carlijn Fransien van der Sluijs, Msc, Den Haag, Netherlands; Tony Martin, PhD, Possilpark Health and Care Centre, Possilpark, Glasgow, UNITED KINGDOM; and Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will be able to detail the demography, toxicology findings, and pathology of Heroin-Related Deaths (HRDs) in the west of Scotland between 2008 and 2011.

This presentation will impact the forensic science community by providing an evaluation of the role of morphine in HRDs, Drug-Related Deaths (DRDs), and non-Drug-Related Deaths (non-DRDs) in 767 cases during a three-year period.

In this study, HRDs in the west of Scotland between 2008 and 2011 were analyzed and compared to non-DRDs in the same period. A total of 767 cases were identified in which morphine was detected postmortem. Information on these cases was extracted from the Glasgow University Forensic Medicine (GUFM) database and analyzed using Excel®.

In 2009, the General Register Office for Scotland reported 545 DRDs in Scotland, with 37% occurring in the Greater Glasgow and Clyde area. A large proportion of these deaths occur due to the use of heroin, which was implicated in 59% of all DRDs in Scotland. Heroin continues to be reported in a large number of DRDs in the west of Scotland, often leading this area to be referred to as the heroin capital of Europe.

There were 323 HRDs identified over the study period. The mean age in these cases was 34.9 years, 84% were male, and the majority of people died in their own home (54.9%). In cases which were not classified as DRDs, the average age was 45.9 years, 69% were male, and 46% of people died in a hospital. Areas within Greater Glasgow and Clyde with the highest percentage HRDs were Glasgow West, Glasgow East, and Renfrewshire. In this population, the median blood morphine concentration in HRDs was 0.26mg/L, which was significantly higher than the morphine concentration in non-DRDs: 0.09mg/L. In the minority of HRDs (37%), only heroin was implicated in the cause of death. Alcohol (35%) and methadone (24%) most often contributed to the cause of death. In 23 cases of all non-DRDs, heroin was administered for medical care prior to death. The median blood morphine concentration in those cases was 0.16mg/L, which was lower than blood morphine concentration in HRDs, but not statistically significant.

The majority of heroin-related fatalities are male with an average age of 34.9 years at death, which means a considerable loss of life compared to the average life expectancy in Scotland. Most deaths occurred at home, indicating there was little time from heroin use to death. Next to heroin, alcohol and methadone were involved in the cause of death in almost 60% of cases. Overall, the mean blood morphine concentration in heroin fatalities was more than 50% higher than in non-DRDs (0.37mg/L vs. 0.24mg/L).

Heroin, Demographic, Postmortem

K35 Analysis of N-Bombs: Quantitation of NBOMe-type Novel Psychoactive Substances (NPS) in Biological Fluids by Liquid Chromatography With Tandem Mass Spectrometry (LC/MS/MS)

Donna M. Papsun, MS, 607 S Olds Boulevard, Fairless, PA 19030; Heidi Schimmelbusch, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to describe the characteristics and effects of NBOMe-class compounds, implement methods for their analysis in biological fluids using LC/MS/MS, and learn about the concentrations of these analytes detected in biological fluids in forensic cases.

This presentation will impact the forensic science community by describing a comprehensive assay for the detection of this emerging class of NPS with known adverse effects. The detection and quantitation of these drugs in toxicology casework will also be discussed.

NBOMes, known as N-Bombs by the drug-using community, are a group of psychedelic substituted phenethylamines being seen with increasing frequency in recreational drug products being sold online and through underground suppliers in the United States. They are derivatives of the 2C family of phenethylamine stimulants first described by Alexander Shulgin throughout the 1980s. 25I-NBOMe is the N-benzyl methoxy derivative of 2C-I; the substitution is considered to increase the potency and psychoactivity of the compound. Substitutions of the other members of the 2C class result in additional members of the NBOMe series. These compounds have gained popularity among recreational drug users as an alternative to LSD and are often impregnated onto blotter papers or administered in powder and liquid formulations. Members of the NBOMe series have been linked to fatal intoxications, characterized by violent behavior, psychosis, and extreme sympathetic stimulation. Case reports of NBOMe use have included hospitalizations and deaths. Due to the substantial risk of toxicity from this group of compounds, and the need to confirm their use, it was necessary to develop testing for the detection of NBOMes for forensic toxicology applications.

A method for the detection of four members of the NBOMe class — 25I-NBOMe, 25B-NBOMe, 25C-NBOMe, and 25H-NBOMe — is described. Since the NBOMes have been reported to be active in sub-milligram doses, a positive ion mode LC/MS/MS procedure was developed for the determination of these compounds in serum, plasma, and whole blood.

Samples were prepared for analysis by a simple protein precipitation process using acetonitrile. Ultra Performance Liquid Chromatography (UPLC) conditions for the LC/MS/MS method included 0.1% formic acid in water vs 0.1% formic acid in methanol, at 0.400mL/min on a BEH C18, 2.1mm x 50mm column. The test is routinely performed qualitatively; however, quantitative values were achieved using the standard addition approach. The calibration range for the standard addition method used a calibration curve from 0.5ng/mL-50ng/mL of each drug. A qualitative urine extraction for the detection of NBOMe samples was developed separately. The NBOMes were extracted from urine using a solid-phase extraction after pH adjustment. Conditions for analysis by UPLC are similar to the blood method.

Since September of 2013, this study has encountered 25 positive cases for the NBOMe drugs, including 22 whole blood samples, one serum/plasma sample, and three urines. Of the 25 cases, 14 screened positive for 25I-NBOMe, three for 25C-NBOMe, five for 25B-NBOMe, and three cases contained more than one of the target drugs (25I-NBOMe plus 25B-NBOMe; 25I-NBOMe plus 25H-NBOMe; and, 25C-NBOMe plus 25H-NBOMe). Of the cases with demographic information available (n=18), the median age was 18 years and included 11 males and seven females.

Available samples were subsequently subjected to quantitative analysis using the standard addition method. Of 12 blood cases tested, 25I-NBOMe was detected in seven of these cases with mean and median concentrations of 2.63ng/mL and 1.82ng/mL, respectively (range 0.79ng/mL-6.3ng/mL). 25C-NBOMe was detected in three of the blood samples, with mean and median results of 2.96ng/mL and 2.18ng/mL (range 2.16ng/mL-4.53ng/mL). In one sample, 25H-NBOMe was present at a concentration of 2.10ng/mL in conjunction with 4.53ng/mL of 25C-NBOMe.

Toxicology Section - 2015

Although quantitation of NBOMe drugs have been previously reported in isolated cases, this is the first documented attempt to develop a comprehensive panel for the most popular NBOMe drugs which can be easily revalidated for new members of the drug class when they appear. The method can be used qualitatively as a screen or with standard addition for confirmation and quantitation. This LC/MS/MS approach provides the sensitivity and specificity necessary for the detection and quantitation of NBOMes in forensic toxicology casework.

NBOMe, Novel Psychoactive Substances, Toxicology

K36 Phencyclidine (PCP) in San Francisco: A Review of 50 Postmortem and Human Performance Toxicology Cases Between 1997 and 2013

Alexander C. San Nicolas, MSFS*, 300 Davey Glen Road, 3801, Belmont, CA 94002; and Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Terrace, 850 Bryant Street, San Francisco, CA 94103

After attending this presentation, attendees will understand the frequency of PCP detection as well as the concentration ranges of PCP in Postmortem (PM) and Human Performance (HP) cases in the City and County of San Francisco.

This presentation will impact the forensic science community by expanding the existing body of scientific knowledge of demographic characteristics in PCP-positive PM cases, Driving Under the Influence (DUI) and other police cases (including toxicologic findings in these cases), commonly analyzed specimens, and ranges of blood concentrations typically encountered in such cases.

The Forensic Laboratory Division (FLD) of the Office of the Chief Medical Examiner (OCME) analyzes evidence from postmortem and human performance cases on behalf of 14 law enforcement agencies operating within the City and County of San Francisco. For PCP, commercially-available Enzyme Linked Immunosorbent Assay (ELISA) kits are used to screen blood (cardiac/central blood in PM cases, venous blood in HP cases) and/or urine received by the FLD. The ELISA cutoffs for blood and urine PCP are 10ng/mL and 50ng/mL, respectively. Following a positive ELISA screen, confirmation and/or quantitation is performed in blood (peripheral blood in PM cases; a new aliquot of venous blood in human performance cases) and/or a fresh aliquot of urine by Gas Chromatography/Mass Spectrometry (GC/MS) with a Limit Of Quantitation (LOQ) of 0.01mg/L. The assay uses tripeleamine as Internal Standard (IS). The observed retention times are: 8.16min (PCP) and 9.96min (IS). The Target (underlined) and Qualifier ions (m/z) for PCP are 91, 200, 242 and for IS are 58, 91, 185, and 197.

In order to determine PM and HP cases involving PCP in San Francisco over the period of interest, the in-house database was manually interrogated.

Twenty HP cases were confirmed to have PCP in blood, in which subjects averaged 42.4 years of age (range: 20–57 years), were predominantly male (n=20; 75%), with a racial distribution of Hispanic (50%), White (30%), Other (5%), Unknown (5%), and Not Available (10%). The PCP blood concentrations in these cases were (mg/L): mean 0.06 (median 0.05, range 0.01–0.11, standard deviation 0.03). PCP was encountered by itself in seven of the 20 cases and in combination with other psychoactive compounds in the remaining 13 cases. The most commonly encountered drugs detected in PCP-positive cases were amphetamines (n=5), cocaine/benzoylcocaine (n=3), ethanol (n=2), methadone (n=2), and THC (n=2).

In addition, there were 30 PM cases involving PCP, 24 of which had peripheral blood concentrations. Thirteen of the 24 also had PCP confirmed in urine. Another four cases had PCP only in urine, one had PCP in cardiac/central blood, and one had PCP measured in liver. Decedents averaged 42.6 years of age (range: 21–62 years), were predominantly male (n=30; 83%), with a racial distribution of White (50%), White Hispanic (40%), Black (7%), and Native American (3%). The manners of death were: 16 accidents, six suicides, five natural deaths, two homicides, and one undetermined. The PCP peripheral blood concentrations (n=24) were: mean 0.23, median 0.13, range 0.01–0.59, standard deviation 0.19. PCP was encountered by itself in only two of the 24 cases. In all other cases, it was present in combination with other psychoactive drugs: morphine/codeine (n=10), cocaine (n=9), ethanol (n=9), amphetamines (n=6), and methadone (n=5).

This presentation offers valuable information on the demographic distribution of PCP users and decedents in the City and County of San Francisco and offers PCP reference blood concentrations. The San Francisco data suggests that PCP remains a popular recreational drug found in many types of cases. These data show that 35% of PCP-positive living subjects apprehended for DUI and other related offenses were more likely to have PCP on its own. In comparison, only 7% of PCP-positive decedents had PCP by itself, suggesting PCP serves as only one compound of a typical poly-substance death involving PCP. Comparison of mean blood concentrations indicates statistically-significant differences in blood concentrations with PCP-positive decedents having concentrations averaging more than 3.5 times higher than those of living subjects. The data presented is useful to forensic toxicologists, medical examiners, pathologists, coroners, attorneys, as well as other law enforcement agents, who need to understand and interpret PCP concentrations in HP and PM toxicologic specimens, for the purpose of their medicolegal investigations.

Phencyclidine (PCP), Postmortem Toxicology, Human Performance Toxicology

K37 **Determination of Methamphetamine Concentrations in Thighbones Buried in Soil**

*Ken-ichiro Nakao, MS**, 8-1 Kawada-cho, Shinjuku-ku, Tokyo 162-8666, JAPAN; and *Kazuhiko Kibayashi, MD**, Tokyo Women's Medical University, Dept of Legal Medicine, School of Medicine, 8-1 Kawada-cho, Shinjuku-ku, Tokyo 162-8666, JAPAN

After attending this presentation, attendees will understand the interpretation of methamphetamine concentrations in the bone tissue of decomposed or skeletal remains.

This presentation will impact the forensic science community by demonstrating the role and importance of toxicological analysis of bone in the diagnosis of death from drug abuse.

Bone samples are used for toxicological analysis of decomposed or skeletal remains. To determine the relationship between the concentrations of methamphetamine in bone and those in blood or muscle, the methamphetamine concentrations in mouse thighbone were determined and these concentrations were compared with those in heart blood and muscles. The methamphetamine concentrations in thighbones buried in soil for 7 to 180 days were also determined.

Male ddY mice were intraperitoneally injected with methamphetamine at doses of 1mg/kg, 5mg/kg, or 10mg/kg or with saline, once a day for seven days (n=25 per group). Heart blood samples were collected under general anesthesia by cardiac puncture and the thigh muscles and thighbones were also removed. Thighbones were buried in soil and left in a chamber maintained at 16.2°C and 62% humidity for 0, 7, 30, 90, or 180 days (n=5 at each time point). Five hundred microliters of heart blood or 0.5g thigh muscle were analyzed using Liquid Chromatography coupled with Tandem Mass Spectrometry (LC/MS/MS). Thighbone samples were sterilized with distilled water and acetone and were dried at 50°C for 24h. The dried thighbones were pulverized with a bead homogenizer and were evaluated using LC/MS/MS.

In all mice groups, methamphetamine concentrations in thighbone samples were higher than those in heart blood and thigh muscle samples. Significantly higher concentrations of methamphetamine were determined in thighbone samples of mice administered a dose of 1mg/kg or 10mg/kg methamphetamine ($p<0.05$). Although methamphetamine was detected in all thighbone samples after a burial period of 7-180 days, methamphetamine concentrations in buried thighbone samples were significantly lower than those in thighbones without burial in all mice groups ($p<0.05$). The results of this study indicate that: (1) methamphetamine accumulates in bone and shows higher concentrations in bone than in blood or muscle; (2) methamphetamine is detectable in bone for up to 180 days after burial; and, (3) methamphetamine shows lower concentrations in buried bone than in blood and muscle; this may be because of its diffusion into the soil.

Methamphetamine, Bone, Decomposition

K38 Supported Liquid Extraction (SLE) as a New Technique for the Clean-Up of Hair Extracts Containing Drugs of Abuse

Jakub Klobut, MSc, Arcadia University, 450 S Easton Road, Glenside, PA 19038; Frank Kero, PhD, Biotage, 10430 Harris Oaks Boulevard, Ste C, Charlotte, NC 28269; Amanda L.A. Mohr, MSFS, Center for Forensic Science, Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will understand a novel method for the clean-up of hair extracts in order to detect drugs of abuse using SLE.

This presentation will impact the forensic science community by introducing a faster and more efficient method for detecting drugs in the hair matrix.

Hair analysis has been regarded as a complementary matrix to blood and urine in forensic cases as it is a very stable matrix, thus allowing for a detection window that is days to years post-exposure. Analyzing hair for the presence of drugs of abuse consists of many steps, initially starting with sampling and cutting of the hair into small segments, which is followed by decontamination, extraction, and clean-up of the hair extract prior to qualitative and quantitative analysis. Drug residues in hair have previously been reported at trace levels, which progressively degrade by oxidation and/or hydrolysis, so the optimization of analyte extraction and clean-up steps are critical components to ensure the quality of method performance.

The objective of this research was to apply a reduced workflow preparation technology to a range of basic drugs extracted from hair. SLE has been used for the determination of drugs in conventional matrices, such as blood and urine, both of which showed high recovery. In the SLE process, the sample is pH adjusted, then loaded in an aqueous phase to ensure the analytes of interest load as neutral compounds. To date, no peer-reviewed literature discussing the application of this technique in hair has been published.

In this study, Biotage® ISOLUTE® SLE+ was compared to traditional Solid Phase Extraction (SPE) for the determination of cocaine, methadone, opiates, and amphetamines using control samples. These samples were prepared by spiking washed drug-free hair in deionized water and Dichloromethane (DCM) prior to spiking with the drugs (methamphetamine, amphetamine, morphine, 6-monoacetylmorphine, codeine, methadone, cocaine, and benzoylecgonine) at a concentration of 0.5ng/mg and 2ng/mg.

Validation of the SLE method was carried out according to the Scientific Working Group for Toxicology guidelines using the control hair samples, which were weighed (20mg) and, together with standards and negative controls, were tested according to specific procedure. One mL of phosphate buffer pH=7.4 and 50µL of β-glucuronidase solution was added to controls containing amphetamines. Samples were sonicated for one hour at 40°C and incubated for one hour. Prior to extraction, 100µL of 10% ammonium hydroxide was added. In controls containing opiates and methadone, 1mL of 0.1M hydrochloric acid was added before sonication for one hour at 40°C and overnight incubation at the same temperature. Before extraction, 100µL of 5% ammonium hydroxide was added to the supernatant. For controls with cocaine, 1mL of methanol was added and samples were sonicated for one hour at 40°C and incubated over night at 40°C. Before extraction, 100µL of 5% ammonium hydroxide was added to the supernatant. Deuterated internal standards for all drugs were used. A set of split samples was extracted by both SPE and SLE+ in order to compare results. Before applying samples (1mL) onto ISOLUTE® SLE+ cartridges, samples were pH adjusted to pH>10 in aqueous environment in buffer. Prior to evaporation, 100µL of 1mg/mL tartaric acid in ethyl acetate was added to samples containing amphetamine. The extracts were then evaporated and derivatized using pentafluoropropionic acid (PFPA):ethyl acetate (2:1) for amphetamines and BSTFA + 1%TCMS for other drugs. The samples were analyzed using Gas Chromatography Mass Spectrometry (GC/MS) in selected ion monitoring mode.

In order to verify the SLE+ method, hair samples from rats, containing amphetamine and methamphetamine, and human hair from forensic and clinical cases were tested in similar fashion. SLE+ was determined to be a suitable alternative to SPE for the quantitation of cocaine, benzodiazepines, methadone, morphine, codeine, and 6-monoacetylmorphine in hair. Amphetamines and methamphetamines were detected in rat hair at concentration ranging from <0.1ng/mg to >5ng/mg with comparable results between the two clean-up methods. Similarly, a wide range of concentrations (from lower than low limit of quantitation to higher than upper limit of quantitation) were determined in human hair samples.

SLE+ provides better efficiency and less solvent waste than SPE and is a suitable clean-up method for hair analysis.

SLE, SPE, Hair

K39 Surface-Enhanced Raman Analysis of Synthetic Cannabinoids Using Gold Nanoparticles and Various Aggregating Agents

Thaddeus Mostowtt, MFS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand the principles of Surface-Enhanced Raman Spectroscopy (SERS), how SERS can be used to lower the limit of detection of synthetic cannabinoids, the effect of using different aggregating agents when combined with gold nanoparticles to enhance the limit of detection, and how SERS can be a fast and easy analysis for drug detection in toxicological samples.

This presentation will impact the forensic science community by demonstrating the application of SERS as a useful procedure for detecting trace levels of synthetic cannabinoids in solution that is rapid, sensitive, and applicable to a variety of biological matrices.

The use and abuse of synthetic cannabinoids has increased significantly in recent years due to their easy access and growing popularity in young adults. Initially, these drugs, known as “Spice” or “K2,” were sold in retail outlets or via the internet and labeled as “not for human consumption” to avoid any possible regulation of the products by the Food and Drug Administration. This popularity led to an increase in emergency room visits due to synthetic cannabinoid intoxication in recent years. As more of these drugs become illegal, new synthetic legal versions of these drugs are being made. This presents problems for the hospitals and the forensic investigator as standard methods may not detect the target drug.

The most common method of screening detection for drugs of abuse in biological samples is the immunoassay; however, this method presents some disadvantages, particularly for newly synthesized compounds. Other problems include cross-reactivity between different synthetic cannabinoids, hook effects, and high cut-off values for determining if the drug is present. More advanced methods have also been used, such as Gas Chromatography/Mass Spectrometry (GC/MS), however these procedures involve complex sample preparation and long run times.

A potential solution to this issue is Raman spectroscopy. This procedure is an under-utilized technique for the detection and identification of drugs due to its perceived low sensitivity for analytes in solution using traditional procedures; however, when Raman spectroscopy is performed in the presence of metallic nanoparticles, signal can be enhanced several orders of magnitude, which is known as SERS. The addition of aggregating agents, generally ionic salts, further increase the signal via the creation of hot-spots due to displacement of the stabilizing agent which leads to a change in the surface charge of the metallic nanoparticle and the ionic strength of the solution. This method has already been confirmed to work for the toxicological detection of benzodiazepines with limits of detection ranging from 1ng/mL-200ng/mL and for THC with limits of detection less than 10ng/mL. In addition, this method can be made portable and used for on-site detection allowing for a faster analysis time.

In this project, gold nanoparticles were prepared using a sodium citrate, hydroxylamine, or borohydrate reduction and aggregating agents were used to enhance the Raman signal of five different synthetic cannabinoids: JWH-018, JWH-073, JWH-081, JWH-122, and JWH-250. Seven different aggregating agents including MgCl₂, CaCl₂, KCl, NaCl, MgSO₄, KNO₃, and Na₂SO₄ were examined at varying concentrations to optimize sensitivity of detection. Other factors, including the concentration of nanoparticles and time and temperature, were also examined. Upon analysis, the Raman spectrum of each synthetic cannabinoid could be easily distinguished when compared to the Raman signal of the powder form of the drug. Nanogram-per-milliliter concentrations can be detected of each synthetic cannabinoid.

These results demonstrate that SERS can be utilized to detect trace amounts of synthetic cannabinoids in aqueous solutions. Therefore, following the extraction of the analyte, SERS can be used as a detection method of synthetic cannabinoids in toxicological samples, which can be useful in a hospital setting, workplace drug testing, and in forensic toxicology laboratories.

SERS, Synthetic Cannabinoids, Toxicology

K40 Characterization of Binding of Ricin Toxin to Cultured Human Lung Cell Line A549

Oluseyi A. Vanderpuye, PhD*, Forensic Science, 504 College Drive, Rm 118, Hartnett Bldg, Albany, GA 31705; Jaderica A. Smith, BS, 5959 Fairington Road, Apt 3H, Lithonia, GA 30038; and James J. Hardy, BS, Albany State University, 504 College Drive, Dept of Natural and Forensic Sciences, Albany, GA 31705

After attending this presentation, attendees will better understand the targets and nature of ricin toxin binding to a human lung cell line and its relationship to potential ricin poisoning incidents. The goals are to understand how ricin-binding proteins on human lung cells can be identified and how some of their properties can be determined. As human lungs are one of the target organs of ricin poisoning, more information on proteins that are involved in enabling ricin toxicity could be helpful in further understanding events in toxicity and in designing or using molecules that reduce ricin toxicity *in vivo*.

This presentation will impact the forensic science community by providing information on ricin target proteins on human lung cells. This is significant since there is more information of ricin binding to animal tissues than there is for human cells. After attending this presentation, attendees will better understand how the interaction of ricin with human lung cell lines can be characterized by electrophoresis and fluorescence microscopy.

The plant protein ricin is a highly toxic protein with no antidote. Toxicity of ricin depends on binding to cell surface galactose and endocytosis. Little work has been done on the characteristics of ricin binding to human lung cells and most studies of the interaction of ricin with cells have involved cells sourced from animals and not humans. The objectives of this study were: (1) to identify lung cell proteins that are bound by ricin; (2) to visualize the binding of ricin to intact lung cells; and, (3) to initiate the development of methods to isolate the lung cell proteins that bind to ricin.

Lung cell ricin-binding was characterized by using lung cell proteins that were separated by sodium dodecyl sulfate polyacrylamide electrophoresis and followed by transfer of the protein profile to nitrocellulose for probing with biotinylated ricin. Major proteins of 150kDa, 100kDa, and 60kDa were bound by ricin in A549 cells and the proteins bound differed from those recognized by ricin in SW-13 adrenal cells, salivary fluid, and serum. SW-13 cells had ricin binding proteins of approximately 100kDa and 60kDa in common with A549 cells but differed in containing a low molecular weight molecule of less than 25kDa which bound ricin. The binding of ricin and RCA-I to intact lung cells was compared by fluorescence microscopy. The protein RCA-I also originates from the plant *Ricinus communis* and has been reported to bind to the same carbohydrate molecules recognized by ricin. Binding to intact A549 lung cells was much stronger for RCA-I than for ricin. Reduction of binding to cells by human serum was also higher for RCA-I than for ricin.

The electrophoretic mobilities of the A549 cell ricin-binding proteins were examined by SDS-polyacrylamide electrophoresis under reducing and non-reducing conditions to see if effects attributable to disulfide bonds could be detected. Three major A549 cell protein bands of approximate molecular masses 150kDa, 100kDa, and 65kDa were bound by ricin after electrophoresis under reducing and electro-transfer to nitrocellulose membranes. The electrophoretic mobility of the 150kDa protein was the same under reducing and non-reducing conditions. The mobility of the approximately 100kDa protein was 8.5mm from the origin under non-reducing conditions compared to 10mm under reducing conditions. The mobility of the approximately 60kDa protein was 15mm from the origin under non-reducing conditions and 17mm from the origin under reducing conditions. Based on these findings, the 100kDa and 60kDa A549 cell proteins that bind ricin may contain disulfide bonds which when intact make these proteins assume a more compact shape.

Batch affinity chromatography was performed on proteins extracted from A549 cells by using the non-ionic detergent Triton™ X-100. The proteins bound by the different matrices, Cibacron Blue-agarose, heparin-agarose, Concanavalin A-agarose, and RCA-I agarose were tested for binding to ricin after SDS gel electrophoresis and transfer of the separated proteins profile to nitrocellulose membranes. The profile of protein that bound to Concanavalin A contained the 100kDa and approximately 60kDa and two proteins in the region of approximately 120kDa to 150kDa as major proteins that were enriched generally compared to proteins that were associated with the other matrices. Therefore, the main ricin-binding proteins in A549 cells also appear to bind to the carbohydrate-binding protein Concanavalin A which binds to carbohydrate structures distinct from those that bind to ricin as well as to different aspects of some structures that bind to ricin.

Toxicology Section - 2015

The conclusions from this study are that: (1) A549 lung cells contain three major ricin-binding proteins; (2) RCA-I, a lectin that is related to ricin, binds to A549 lung cells much more efficiently than ricin; (3) human serum is more effective at competing with RCA-I for binding to A549 cells than it is for competing with ricin for binding to A549 lung cell; (4) two of the major ricin-binding proteins from A549 cells may contain disulfide bonds; and, (5) the major ricin-binding proteins in A549 cells have carbohydrates that are also bound by the lectin Concanavalin A. These observations may help in the eventual isolation of these proteins to determine details of their roles in the toxicity of ricin for human lung cells.

Ricin, Lung, Glycoproteins

Toxicology Section - 2015

K41 The Psychological Autopsy: Psychiatry & Behavioral Science and Toxicology in a Working Relationship — Suicide—A General Overview

Dean De Crisce, MD, Special Treatment Unit-Annex, 15 Paddock Street, Avenel, NJ 07001*

After attending this presentation, attendees will understand and appreciate the recent trends in suicide-related deaths in the United States, groups of individuals at high risk for completed suicides, preventative factors in reducing suicide, and the common means and methods utilized in completed suicides.

This presentation will impact the forensic science community by demonstrating the scope and factors involved in suicide-related deaths in the United States in an effort to assist postmortem analysis and allow the identification of intervention and prevention strategies.

Suicide is a top-ten cause of death in the United States and the second leading cause of violent death following accidental injury. According to the Center for Disease Control and Prevention, the rate of completed suicides has increased in the last ten or more years, and has varied based on demographic factors such as race, region of residence, age, and gender. It is estimated there are at least ten times the number of self-harm attempts as there are completed suicides. The highest rates of completed suicide have been in White males, aged 45 to 64 years, living in western states; however, there are substantial numbers of suicide deaths across all demographics and states.

Much of the literature regarding suicide deaths has been the result of research incorporating postmortem analysis and psychological autopsies. Firearms have been the most common method of completed suicide in recent years, followed by suffocation and toxic ingestion. According to the American Foundation for Suicide Prevention, the majority of those completing suicide suffer from mood disorders, substance use disorders, schizophrenia, and personality disorders; approximately two-thirds of those individuals expressed their intent prior to their death.

Public and mental health literature has investigated risk factors for suicide. Risk factors for suicide include major mental disorders, substance use, prior suicide history, family history of suicide, trauma, serious medical illness, environmental and interpersonal losses, access to lethal methods, barriers to accessing treatment, and exposure to suicide. Protective factors that may decrease risk of suicide include strong social support, mental health and substance abuse treatment, restricted access to lethal methods, and life-affirming cultural and religious participation.

Suicide is a preventable cause of death. Far beyond the individual, the effects impact society emotionally, legally, and financially. More research is needed to identify clinical and sociologic interventions to reduce this tragic loss. Forensic science, through postmortem analysis and psychological autopsy, serves as a major contributor to understanding this phenomenon.

Suicide, Psychological Autopsy, Toxicology

Toxicology Section - 2015

K42 The Psychological Autopsy: Psychiatry & Behavioral Science and Toxicology in a Working Relationship — Medicines of the Mind

Dan T. Anderson, MS, Los Angeles County Dept of ME-Coroner, 1104 N Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will understand the different classes of antidepressant and antipsychotic medications in society, analytical profiles of recently approved Food and Drug Administration drugs, how these medications are evaluated in context with the cause and manner of death, and how these drugs are interpreted when the manner of suicide is disputed by a family, leading to a psychological autopsy being performed.

This presentation will impact the forensic science community by serving as a reminder of the importance of toxicology testing, along with its scope in assessing cause and manner of death.

Antidepressant and antipsychotic medications are widely prescribed in our society to treat signs and symptoms of depression as well as psychosis. Antidepressants can be categorized into several subcategories to include older generation drugs such as the tricyclic and monoamine oxidase inhibitors. Newer generations of the antidepressant medication include Selective Serotonin Reuptake Inhibitors (SSRIs) and Serotonin-Norepinephrine Reuptake Inhibitors (SNRIs) and combinations thereof. Antipsychotic medication is generally segregated into two types: “typical” antipsychotic drugs that have the potential of severe side effects to the patient and “atypical” medications that are considered a newer generation class of drugs with lesser side effects. The public has definitely been educated about these drugs and, even with the emerging drugs, by the bombardment of advertisements in magazines, newspapers, and television segments. With such prevalence and public knowledge, prescription medication needs to be assessed in routine medical examiner/coroner cases where the cause and manner of death may or may not be known.

The role of a postmortem toxicologist is varied. The first is to assist the medical examiner/coroner/pathologist in assessing the case and determine the level of analytical testing necessary based on the case history, death scene investigation, incoming mode and manner of death, drug or prescription medications collected, autopsy findings, family accusations, and any other possible question that would have to be answered tomorrow with today’s analysis. The second role is actually analyzing the biological specimen for the presence or absence of drugs/prescription medications with the appropriate quality control measures in place to ensure accurate and precise results. The last role is to provide the results to the medical examiner/coroner/pathologist and possibly assist with the interpretation of the drugs and their concentrations in respect to their autopsy findings and investigations.

For cases where the cause and manner of death is not evident, a general comprehensive toxicology screen is performed and generally accounts for a wide array of drugs and prescription medication available in society; however, for cases where the cause and manner of death appears to be obvious, such as non-drug related suicide involving a hanging or gunshot wound to the head, toxicology testing may not be all that complete. Its important to note that in order to evaluate the psyche of the decedent, a more comprehensive panel of drug tests, including antidepressant and antipsychotic medications, may need to be assessed to understand their level of contribution toward the actual cause and manner of death.

Toxicology, Antipsychotics, Antidepressants

Toxicology Section - 2015

K43 The Psychological Autopsy: Psychiatry & Behavioral Science and Toxicology in a Working Relationship — Psychological Autopsy and the Assessment of Motive

Michael Welner, MD, 224 W 30th Street, Ste 806, New York, NY 10001; and Dan T. Anderson, MS, Los Angeles County Dept of ME-Coroner, 1104 N Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will understand the purpose of psychological autopsy and the methodology necessary, including the requisite sources of information, for informing the probabilities involved in death investigation. Attendees will also be informed about confounders to the interpretation of data and legal thresholds for testimony.

This presentation will impact the forensic science community by demonstrating how medicine, toxicology, and other forensic data are properly integrated into death investigation at the psychological level. Attention to the assessment of motives is an essential component of death investigation as well, and this presentation enables the participant to learn its judicious integration into death investigation. Finally, this presentation inventories those cases in which special caution is reserved for the potential ambiguity in motive and contributions to errors.

Death investigation confronts the challenge of resolving the likelihood of suicide vs. homicide vs. accident or natural causes. It is the ideal platform upon which psychiatric and psychological understanding can be infused into the work of the coroner and vice versa. It is also an overlooked aspect of criminal responsibility and pre-sentencing determinations in murder and manslaughter cases. Death investigation is often a vivid illustration of the necessity to embed toxicology analysis into otherwise plentiful but equivocal data. Highly publicized deaths of celebrity actors and musicians revisit these challenges of accidental death vs. intentional overdose and even murder.

Forensic psychiatric assessment draws from human evidence, namely, interviews of collateral informants. Accounting for the conflicts and agendas of these witnesses is important but does not diminish the vital contribution of those informants to reconstructing the choices and movements of the deceased and potential nefarious actors antecedent to death. This includes patterns and sequence of medications and substances ingested, accounting for pertinent medical history and timing.

Like other forensic behavioral science assessment, death investigation is a contemporaneous examination that assesses factors specific to the time of the death event and its immediate past. Unlike other forensic assessment, psychological autopsy is typically routed to consulting forensic pathologists for their own consideration but is more restricted in open court testimony to an inventory of suicidal risk factors.

The assessment of motive is essential to any consideration of homicide and as such is a component of psychological autopsy when murder is under consideration. Different source materials inform a similar endpoint of “why” and “why then,” reconstructing both timing and progression. The complexity of this exercise requires openness to evidence of primary, secondary, and tertiary motive; conscious and unconscious motive; and, material and psychological gain. Reconstructive evidence focusing on the circumstances of the death event advances a range of forensic psychiatric questions and forensic medicine contributions to justice.

Psychological Autopsy, Death Investigation, Motive

K44 The Psychological Autopsy in Practice: Applying Behavioral Science to Mode-of-Death Investigations and a Case Study

Lauren Reba-Harrelson, PhD*, PO Box 1404, Columbus GA 31902

After attending this presentation, attendees will be able to identify basic methodology and types of data considered in a comprehensive approach to conducting a psychological autopsy and apply information obtained through this practice to a mode-of-death determination.

This presentation will impact the forensic science community by demonstrating the possible utility of the psychological autopsy as a collaborative clinical practice tool for establishing mode of death in complex determinations related to alleged suicide.

This presentation provides an overview of the structure and function of the psychological autopsy, a comprehensive, objective retrospective analysis a decedent's state of mind, and actions at the time of death. The history of the psychological autopsy will also be described and a case example will be provided to engage attendees in the process of conceptualizing data obtained in the process of the psychological autopsy and making associated decisions associated with determining the mode of death.

The classification of the mode of death (natural, accident, suicide, or homicide) hinges on the intention of the decedent in relationship to the death. Since its conception in the late 1950s, the psychological autopsy has been used in some medical examiner and coroner's offices as a tool by which final death determinations can be made, particularly in unclear cases of alleged self-inflicted death.¹ In certain contexts, the mode of death may be undermined or equivocal or an outside party protests the death determination. In such circumstances, the psychological autopsy allows investigative principals of behavioral science and specialized knowledge of mental health professionals to be applied to the process of classifying deaths through a comprehensive analysis of many aspects of a decedent's mind around the time of death.² It accomplishes this through a thorough analysis of a wide variety of collateral sources (e.g., interviews and personal, educational, professional, and investigative documents) to identify lifestyle and behavioral history, as well as a breadth of cognitive and personality factors that contribute to that history, and more specifically, the decedent's role in the death.

While relatively rare in the practice of most medical examiners' or coroners' offices, the psychological autopsy can provide a unique opportunity for collaboration between forensic mental health professionals and personnel in disciplines integral to death investigations. The majority of death determinations may not necessitate the assistance of mental health professionals, namely because a medical examiner or coroner typically uses the determined method of death as a guideline for the mode of death. Moreover, based on time, cost, and expert availability, a psychological autopsy may not be possible or necessary. Further, some criticism of the utility of the psychological autopsy, both as a research tool and in practice, may contribute to limiting its use.^{3,4} Limitations of the practice will be addressed, as well as the utility of a rigorously and objectively approached analysis of aspects of the decedent's life in the context of cases in which the mode of death is in question. Ultimately, it is opined that a comprehensively conducted psychological autopsy may help to elucidate factors contributing to a decedent's intentions surrounding death not otherwise clarified through more traditional means of medicolegal death investigation. Approaches to facilitating collaborations between mental health professionals qualified to conduct psychological autopsies and offices of medical death investigations will also be discussed.

Psychological Autopsy, Mode of Death, Suicide

K45 The Psychological Autopsy as an Aid to Scientific Investigation: The Application of the Italian Model to a Cold Case Murder

*Laura Volpini, PhD**, via dei Sulpici, 62, Rome 00174, ITALY; *Luciano Garofano, PhD**, Via G. D'Annunzio n.9, Parma 43100, ITALY; *Jacopo Taloni, MS*, Rome, ITALY; and *Cristina Mazza, Str. Mammagiolla 3B, Viterbo, ITALY*

The goal of this presentation is to inform attendees of the Italian model of the psychological autopsy which is adopted in murder cases and cold cases, in addition to problematic death cases.

This presentation will impact the forensic science community by comparing the traditional application of the psychological autopsy with the new Italian model.

Concerning the psychological autopsy in Italy, De Leo et al., beginning with and integrating models of Farberow and Shneidman, Ebert, and Canter, defines it as the analysis of the victim's characteristics and the interactive processes that link the victim and offender.¹⁻⁴ The model proposes guidelines for the analysis of the psychological connection between the victim and the offender and focuses on behavioral risks, relational vulnerabilities, and possible levels of victim-offender connection.

The goal of this study is to determine what kind of relationship there was between the victim and the offender and, consequently, which hypotheses can be utilized for the possible motive and clues about the likely murderer. This study proposes an analysis of possible communicative goals of violent action, reconstructed on the basis of the analysis of the crime scene and other scientific evidence. The investigative hypotheses that emerge from this analysis are then cross-referenced with other findings of investigation.

The psychological autopsy, together with the analysis of violent and communicative action, represents the Italian model for the analysis of unsolved murders and cold cases.⁵

This presentation will describe the application of the model by De Leo in the scientific investigation in a cold case which is well known to the Italian news media. In 1990, the murder of a young 19-year-old girl occurred in the office where she worked. Analysis consisted of review of legal documents, videotapes of television programs in which her sister and parents participated at the time, letters written by the victim, and psychological interviews conducted with her sister and mother.

In the first phase of the investigation, an analysis was made of the contents of documentary material, which was "questioned" with the psychological autopsy guidelines. At this same time, scientific investigations identified the alleged murderer's DNA on the girl's shirt and bra and, via old autopsy photos, identified an alleged bite on the girl's left breast.

In the second phase of the investigation, letters of the victim and psychological interviews of her mother and sister were analyzed to determine the murderer's possible motive and to document the laundry habits at the victim's home.

The identification of the murderer was determined to be the victim's boyfriend. The substantial findings of the interdisciplinary approach adopted in this case led to the boyfriend's conviction with a 24-year prison sentence for the first case, followed by "not guilty" decisions in the second and third case.

Psychological Autopsy, Scientific Investigation, Interdisciplinary Group

K46 Utility of Oral Fluid in Driving Under the Influence of Drugs (DUID) Investigations

Christine Moore, PhD, DSc, Immunalysis Corporation, 829 Towne Center Drive, Pomona, CA 91767*

After attending this presentation, attendees will better understand the potential role of oral fluid testing for investigations into DUID. Attendees will learn that drugs as well as alcohol are responsible for, or at least a factor in, traffic accidents.

This presentation will impact the forensic science community by emphasizing the advantages and viability of testing oral fluid in DUID situations.

Currently, blood or urine is collected for toxicological analysis in suspected cases of DUID; these take time to obtain from a driver, allowing drugs to dissipate from the body. Specimens collected proximate to the traffic stop have a higher probability of containing recently ingested substances which may be potentially impairing. Oral fluid has significant advantages over currently used biological samples, specifically fast, easy collection at the roadside or at a detention facility; rapid collection allows drugs currently circulating in the body to be preserved for analysis. Technological improvements have promoted the use of oral fluid analysis for various applications, including DUID. Additionally, collection devices have been improved, laboratory procedures have become routine, and drug test panels have been expanded.

Over the last decade, numerous roadside surveys in the United States and Canada have established the validity and viability of oral fluid collection for the determination of DUID; drug prevalence rates of 14%-16% have been reported, with marijuana accounting for approximately half of the positive results. An overview of various survey results, drug prevalence rates in drivers, as well as field studies involving both roadside tests and confirmatory specimen analysis will be presented.

Because more and more field studies involving oral fluid are being performed, guidelines for the implementation of data-collection projects have been developed by a subcommittee of the Joint American Academy of Forensic Sciences/Society of Forensic Toxicology (AAFS/SOFT) Drugs and Driving committee. The guidelines are intended for the use of researchers planning to collect information on drug intake from stopped drivers. Focal points of field studies include ways to identify drivers under the influence of drugs in a more efficient and effective manner and to deter drug intake prior to driving by demonstrating reliable drug detection.

In a separate consensus meeting of experts recruited from survey respondents and members of the National Safety Council Alcohol, Drugs and Impairment Division, previously recommended drug concentrations for blood and urine analysis were updated to include oral fluid as a sample matrix.¹ Both of these initiatives will be discussed in the presentation.

Oral Fluid, Drugged Driving, Roadside Testing

Toxicology Section - 2015

K47 An Evaluation of Oral Fluid Testing Devices During Drug Influence Evaluations

Kyle J. Clark, MA, Institute of Police Technology and Management, 12000 Alumni Drive, Jacksonville, FL 32224*

After attending this presentation, attendees will understand the effectiveness of oral fluid testing when used in a law enforcement capacity and compare its effectiveness to a current accepted test.

This presentation will impact the forensic science community by providing an understanding of the needs and limitations available to Driving Under the Influence (DUI) enforcement regarding drug-impaired driving as well as the evaluation of the effectiveness of an oral fluid testing device in this context.

Oral fluid testing is rapidly advancing in accuracy and efficacy within the DUI enforcement community. The biggest hurdle for the acceptance of evidential oral fluid testing deals with the accuracy of the test. A secondary hurdle is the length of time required for the testing process. Both of these hurdles have a significant impact on law enforcement roadside investigations. A testing process that is inaccurate can result in the improper release of a drug-impaired driver, leading to drug-using drivers becoming more confident in their ability to escape detection, and can reinforce the behavior. Inaccurate results can also result in the improper arrest of an innocent motorist, resulting in the deprivation of civil rights. Law enforcement officers have limitations in the detention of motorists in the absence of evidence of a crime and courts have limited the length of detention of a motorist in non-criminal traffic infractions. A roadside testing process that consumes too much time can violate constitutional protections provided in the United States Constitution against unreasonable seizure. For roadside testing to be a viable tool for law enforcement, it must meet both of these requirements, coupled with legislative provisions permitting its use.

A recent certification training conducted as part of a drug evaluation and classification program provided a pool of 95 subjects who were suspected of drug impairment. These subjects were examined for physiological indicators of drug usage as part of a drug-influence evaluation using methods proven effective in both laboratory and field studies. During the evaluation, candidate Drug Recognition Experts (DREs), under the supervision of an experienced DRE instructor, identified physiological signs in the form of pupil size and nystagmus, pupillary reaction to light, psychophysical indicators of divided attention impairment, and collected vital signs to opine if the subject was impaired and the most likely category (categories) of drug responsible. Toxicological samples were collected from each subject in the form of oral fluid and urine and tested onsite. The results of the oral fluid tests were compared with the results of the urine testing and both were compared with the opinions reached during the drug-influence evaluation. This presentation will provide an evaluation of the Alere™ DDS2® device for both its accuracy when compared with the drug-recognition expert opinions and the results obtained from MEDTOX® VERDICT® urine field screening devices, as well as the time element required for the testing process.

Drug, Impairment, Oral

K48 The Perilous Practice of Predicting the Past: Does Retrograde Extrapolation Accurately Predict Prior Blood Alcohol Level?

Ronald L. Moore, Esq., JD, 15635 Alton Parkway, Ste 120, Irvine, CA 92618*

After attending this presentation, attendees will better understand the accuracy of retrograde extrapolation in predicting prior blood alcohol levels in arrested subjects.

This presentation will impact the forensic science community by challenging the accuracy of predictions of Blood Alcohol Concentration (BAC) often made by forensic scientists in court using data from arrested subjects.

Retrograde extrapolation is often used in criminal prosecutions to predict the alcohol level at the time of driving for people arrested for Driving Under the Influence (DUI). The calculations are based on either a blood or breath test taken at a later time. The accuracy of these predictions is often vigorously challenged in legal proceedings. A considerable body of literature exists on alcohol metabolism that is often used to substantiate or undermine such calculations. Much of this data is from laboratory studies rather than under real-world testing conditions.

In the present study, data was collected from the case files of two southern California law firms with significant DUI defense case loads. Cases selected for the study were those where arrest reports indicated that the subject submitted to a pre-arrest breath test at roadside, which was then followed by either a blood or breath test after arrest. A total of 234 cases qualified: 160 males and 74 females, with an average age of 33 years (range 17 to 79 years). A comparison was made between the average of the pre-arrest results to the average of the post-arrest results to determine the direction of alcohol metabolism (rising or falling) during the intervening period and the magnitude of the change over the interval. On average, it took 28 minutes from driving to the first field breath test and, on average, an additional 45 minutes to complete the post-arrest chemical test. Of the 234 subjects, the blood alcohol level went up or remained the same in 108 subjects and went down in the remaining 126 subjects. In addition, calculations were made using typical retrograde extrapolation procedures to estimate the BAC at the time of the first chemical tests based on the time and results of the second set of chemical tests (using an elimination rate of 0.015g% per hour, applied to the time difference between the pre-arrest tests and the post-arrest tests). Fully 75% of the predicted BACs were higher than the actual BAC measured by field breath test. There was a significant difference between the likelihood of overestimating the field BAC based on whether the post-arrest test was blood or breath. If the second test was blood, 86% of the BAC estimates were higher than the field breath test, while if the second test was breath, only 65% of the estimates were higher than the field breath test. This presentation will graphically present this data and give further statistical treatment.

Retrograde, Extrapolation, BAC

K49 Evaluation of the Impact of Expanding Enzyme-Linked Immuno-Sorbent Assay (ELISA) Screening in Driving Under the Influence of Drugs (DUID) Investigations

Aileen Lu, HBSc, 651 Brooke Road, Apt 58-E, Glenside, PA 19038; Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038; Ayako Chan-Hosokawa, MS, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will better understand the prevalence of the therapeutic drugs carisoprodol, meprobamate, and zolpidem in blood samples from DUID arrests. Attendees will be able to use the data to justify the use of ELISA testing for these compounds as part of a standardized drug screening approach in DUID investigations.

This presentation will impact the forensic science community by increasing knowledge of rates of these therapeutic drugs among the population of drivers arrested for DUID. The results should encourage other laboratories to test for these impairing drugs in DUID cases.

Historically, investigating agencies in North America have employed different standards and approaches to DUID testing. Many laboratories or agencies requesting testing in DUID cases rely on immunoassay (ELISA) screening methods which frequently do not employ zolpidem (Ambien®) or carisoprodol (Soma®) assays as part of their scope. A recently published set of standardized guidelines by Logan et al. added carisoprodol and zolpidem to the recommended scope of drug testing in DUID arrests.¹ These central nervous system depressant drugs have been reported to appear frequently in DUID cases in a 2012 survey of toxicology laboratories across the United States. There is still significant variability in terms of the scope of testing employed by different toxicology laboratories. This results in incomplete datasets in which drug incidence patterns are difficult to ascertain.

The purpose of this study was to determine what the incidence of carisoprodol and zolpidem are in a DUID population, in order to assess the frequency with which potentially impairing drugs might go undetected.

A large dataset (n=1,672) of drug screen results from DUID investigations between June 2013 and June 2014 was provided by NMS Labs in Willow Grove, PA. Toxicology results were obtained on blood samples using a Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS) method that was validated according to Scientific Working Group for Toxicology (SWGTOX) guidelines. The method tests for approximately 280 common therapeutic and abused drugs and their metabolites. Positive cases were confirmed and quantified by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) or Gas Chromatography/Mass Spectrometry (GC/MS). Results specifically for zolpidem and carisoprodol and its metabolite meprobamate were evaluated, as well as data on other drugs and alcohol present in these cases.

Zolpidem was found to be positive in 5.3% of cases (n=89). Among the cases which tested positive for zolpidem, many were positive for other drugs among which opiates (20%, n=18), benzodiazepines (19%, n=17), and alcohol (18%, n=6 (33 of 89 tested)) were most prevalent. Carisoprodol and/or meprobamate were positive in 5.9% of cases (n=99). Among the cases which tested positive for carisoprodol and/or meprobamate, other drugs present included opiates (62%, n=61) and benzodiazepines (53%, n=53).

Following assessment of these results, ELISA screening kits from Neogen® for carisoprodol, meprobamate, and zolpidem were validated, and a further 300 random blood samples in DUID investigations that had been tested according to a more limited protocol were subjected to ELISA testing for these three drugs. Positive results were confirmed using a Solid Phase Extraction (SPE) extraction method followed by LC/MS/MS or GC/MS.

DUID, Carisoprodol, Zolpidem

K50 Sleep-Driving Is a Nightmare: Driving Under the Influence of Zolpidem Cases in Colorado

Sarah Urfer, MS, ChemaTox Laboratory, Inc, 5401 Western Avenue, Boulder, CO 80301; and Jaime Morton, ChemaTox Laboratory, Inc, 5401 Western Avenue, Boulder, CO 80301*

The goal of this presentation is to assist attendees in identifying signs and symptoms of zolpidem impairment and evaluate whether the zolpidem levels correlate with observed impairment, based on a study of all zolpidem-positive cases from July 2009 to July 2014 which were tested by ChemaTox Laboratory. The study focused on identifying the following: behaviors that appear in multiple reports, the most frequent multiple-drug intoxication combinations with zolpidem, and the concentrations of zolpidem in both single- and multiple-drug intoxication cases. Selected cases are examined in detail to highlight specific traits.

This presentation will impact the forensic science community by informing attendees that if a laboratory is not looking for zolpidem in their routine testing, it is likely missing these cases. Relying on law enforcement to request zolpidem testing is not sufficient to detect many of these cases, as people often do not inform officers they are taking zolpidem. The popularity of zolpidem, along with the sensationalized publicity surrounding the possible side effects, have led to common themes in cases. These themes include involuntary driving/intoxication, sleep driving, tolerance to the drug effects, and residual levels from the night before. All of these possible issues should still be considered; however, knowing and understanding the common features of these cases and the available research on the topic are critical for the most accurate evaluation of a case. It is imperative that the forensic science community and the public be educated about the dangers associated with driving under the influence of zolpidem.

Introduction: Zolpidem, commonly known as Ambien®, is a z-drug. Z-drugs comprise a class of non-benzodiazepine sedative-hypnotics typically prescribed for the treatment of insomnia. Zolpidem has a relatively short half-life of 2-5 hours and is rapidly eliminated. Zolpidem is intended to be taken immediately prior to going to sleep when the individual taking it is able to devote eight full hours to resting. Incidents of individuals driving under the influence of zolpidem, often to a substantially impaired degree, are becoming more frequent. In the past few years, the proportion of zolpidem-involved Driving Under the Influence of Drugs (DUID) cases tested by ChemaTox has increased. In 2011, zolpidem was the sixth most common drug/drug class in DUID cases tested by ChemaTox; by 2013, it had become the fourth most common drug. The zolpidem medication guide infamously cautions the user against “sleep-driving.” Concern about potential residual levels recently led the FDA to significantly decrease its dosage guidelines. Although more research and education have been provided in the forensic community, the most typical defense used in DUID-zolpidem cases in Colorado is that of involuntary intoxication. Of the cases submitted to ChemaTox, incidence of true involuntary intoxication is rare. Although individuals suspected of DUID-zolpidem often experience confusion, blood levels within expected therapeutic range, and lack of memory of the incident, this does not negate individual responsibility. Analysis was conducted of several typical and remarkable zolpidem-involved cases undertaken by ChemaTox within the years 2009-2014.

Objective: To identify signs and symptoms of zolpidem impairment and evaluate whether zolpidem levels correlate with observed impairment in all zolpidem-positive cases received by ChemaTox between July 2009 and July 2014. The study focuses on identifying the following: behaviors that appear in multiple reports, the most frequent polydrug intoxication combinations with zolpidem, and the concentrations of zolpidem in both single drug and polydrug intoxication cases. Selected cases are examined in detail to highlight specific traits.

Methods: Zolpidem-positive blood samples from DUID cases submitted to ChemaTox within the timeframe studied were evaluated. Samples were screened via Enzyme-Linked Immunosorbent Assay (ELISA). Confirmation testing was performed via Gas Chromatography/Mass Spectrometry (GC/MS) or Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), both with limits of detection of 20ng/mL and limits of quantitation of 50 g/mL for zolpidem. Samples were tested via ELISA and GC/MS or LC/MS/MS for any other requested drugs. Law enforcement case reports are not routinely provided to the laboratory. Reports were requested for all cases and, when available, were analyzed for documented indicia of impairment, subject demographics, and whether zolpidem or other drug use was admitted by the subject.

Toxicology Section - 2015

Results: In DUID cases undertaken by ChemaTox between 2009 and 2014, the most common drugs/drug classes detected were, in descending order, D-9-tetrahydrocannabinol, benzodiazepines, amphetamines, zolpidem, opiates, cocaine, oxycodone, and tramadol. Zolpidem was confirmed in 203 cases (concentration range: <50ng/mL-2,400ng/mL). In available police reports, documented indicia of impairment included erratic weaving and lane travel, “ping-ponging” or colliding with multiple stationary objects, difficulty keeping eyes open, hallucinations, poor memory of recent events, difficulty following instructions and answering questions, and poor reaction time.

Conclusion/Discussion: If a laboratory does not routinely test for zolpidem, it is likely failing to detect impairment in zolpidem-involved cases. Relying on law enforcement to request zolpidem testing is not sufficient as subjects frequently do not inform officers that they are taking zolpidem. The popularity of zolpidem along with sensationalized publicity surrounding the possible side effects have led to trending defense strategies, including involuntary driving/intoxication, sleep driving, tolerance to drug effects, and residual concentrations. All of these potential explanations should be considered; however, familiarity with common themes of these cases and available research are critical for accurate case evaluation. It is imperative that the forensic community and the public be educated about the dangers associated with driving under the influence of zolpidem.

Zolpidem, DUID, Driving Impairment

K51 Synthetic Cannabinoids in Operating While Intoxicated (OWI) Casework: Field Observations and Outsourced Testing

William R. Johnson, BA, Wisconsin State Lab of Hygiene, Toxicology Section, 2601 Agriculture Drive, Madison, WI 53718*

After attending this presentation, attendees will better understand how synthetic cannabinoid impairment presents at roadside. This presentation will also enhance existing case evaluation skills which are used in pursuing initial negative results that might be augmented by additional testing.

This presentation will impact the forensic science community by providing insight into the prevalence of synthetic cannabinoids in recent Wisconsin OWI casework and will include some cases utilizing Drug Recognition Experts (DREs). Casework examples will demonstrate the utility of targeted external analyses for potentially impairing substances not included in a laboratory's routine scope of testing.

Synthetic cannabinoids usage has been increasing at a rate faster than most forensic laboratories can develop and validate analytical procedures. In cooperation with the Wisconsin Bureau of Traffic Safety, select casework including 16 DRE cases listing potential synthetic cannabinoids use were forwarded to NMS Labs for synthetic cannabinoids testing since March 2012, based on information provided by law enforcement agencies. This work encompasses a total of 48 cases (n=43 males, n=5 females) at least two of which involve a motor vehicle death. Where narratives or DRE evaluations were available, subjects often self-reported cannabis or synthetic cannabinoids use, including brand and frequency. The results of routine ethanol and drug testing were fairly unremarkable. Twenty-six of 48 cases (54%) were negative for synthetic cannabinoids. Twenty-two of 48 cases (46%) had at least one synthetic cannabinoid compound detected and five of 48 cases (10%) had between three and seven synthetic cannabinoids detected. The synthetic cannabinoids compounds identified and their prevalence include: JWH-018 5-chloropentyl (n=1); JWH-018 (n=4); JWH-022 (n=3); JWH-081 (n=2); JWH-122 (n=5); JWH-210 (n=3); AM-2201 (n=12); UR-144 (n=5); and, XLR-11 (n=11).

While acknowledging standardized field sobriety tests were not specifically validated for synthetic cannabinoids or equally applied across these specimens, the types of impairment noted were mostly consistent with the cannabis category. It is also worth noting individuals under the influence of synthetic cannabinoids can demonstrate impairments consistent with other drug categories. Another challenge of testing for synthetic cannabinoids is the stability of these compounds in whole blood which has not been fully represented in the literature. While the challenge of analytical testing for these and other synthetic compounds will remain for some time, laboratories should be aware of outside resources and funding that may provide that testing as casework warrants.

Synthetic, Cannabinoid, Impairment

K52 Development of an Analytical Method for Nootropic “Smart” Drugs in Biological Fluids

Mollie Mares, BS, 1845 Clarendon Drive, Easton, PA 18040; Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038; Donna M. Papsun, MS, 607 S Olds Boulevard, Fairless, PA 19030; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will better understand the class of nootropic (“smart”) drugs, be able to describe the relative merits of different models of analysis, and implement a method to identify, confirm, and quantitate the drugs in biological fluids.

This presentation impacts the forensic science community by describing the development of an analytical method for newly emerging drugs that are subject to misuse and abuse and can cause mind-altering effects. The drugs are not currently regulated and are emerging online and in illicit supply chains.

Smart drugs, also known as nootropics, are an emerging area of growth in recreational drug use with implications for forensic toxicology. The drugs have stimulant properties and are alleged to boost brain function and cognition. The media attention on these drugs has increased within the last few years. The drugs have developed an underground following and are commonly sold online and in illicit supply chains. Most have not been approved or scheduled in the United States and are therefore of concern to regulators such as the Food and Drug Administration and Drug Enforcement Administration. There are ongoing investigations in the applications of smart drugs in the treatment of Alzheimer’s disease, Huntington’s disease, and attention-deficit hyperactivity disorder. The stimulant properties of the drugs have led to their use in academic doping and as drugs of abuse. Some drugs are also prohibited by the World Anti-Doping Agency.

The goal of this project was to develop a single analytical method for screening, confirmation, and quantification of a series of the more widely known smart drugs in blood and urine. Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Mass Spectrometry (LC/MS) were investigated to determine the optimum approach for sensitivity and ability to detect a broad range of compounds, specifically piracetam, pramiracetam, aniracetam, modafinil, adrafinil, ciproxifan, and noopept.

Analytical methods included the use of GC/MS. Analysis was performed using an Agilent® 6890/5973 GC/MS system with an Agilent® DB-5MS column (15m x 0.25mm; 0.25µm). Temperature programs starting at 70°C and injection port temperatures as low as 175°C were evaluated. The racetam class of drugs which contain a pyrrolidineacetamide structure (e.g., piracetam, pramiracetam, and aniracetam) were thermally unstable and degraded into three to five derivative structures. The structures of the degradation products were tentatively identified based on molecular weight and their mass spectra were added to a database to assist with identification of breakdown artifacts in future toxicological analysis. Adrafinil, a modafinil prodrug, was found to degrade to modafinil during GC/MS analysis by water loss, resulting in an inability to distinguish between the two substances. Even at low injection port temperatures, degradation persisted. Derivatization of the compounds using BSTFA with 1% TMCS to form TMS derivatives as a means of stabilizing the compounds was also investigated, but also failed to produce single stable chromatographable analytes.

As a result of the demonstrated thermal instability of these drugs, LC/MS was investigated. A successful analytical method was developed using an Agilent® 1100 series system with an Eclipse Plus C18 column (4.6mm x 100mm; 3.5µm), a gradient consisting of 10mM ammonium acetate buffer (pH 4) and 50:50 acetonitrile:isopropanol (v/v), a flow rate of 0.6mL/min, and positive (aniracetam, piracetam, pramiracetam, noopept, ciproxifan) and negative (modafinil and adrafinil) ionization. The ions that were monitored are as follows: aniracetam 220.1m/z; piracetam 143.1m/z; pramiracetam 270.1m/z; noopept 319.1m/z; ciproxifan 271.1m/z; modafinil 272.1m/z; and, adrafinil 288.2m/z. All of the peaks were baseline resolved.

Following characterization of the above conditions, extracts of blood and urine samples were prepared using supported liquid extraction procedures and evaluated for recovery cleanliness, reproducibility, limits of detection and quantitation, accuracy, and precision. In conclusion, LC/MS provided a superior means of identification for the target compounds due to the stability of the compounds under these analytical conditions. The methods evaluated were effective for the detection of the targeted compounds in biological fluids, such as whole blood and urine, at toxicologically meaningful concentrations.

Smart Drugs, Nootropics, LC/MS

K53 Adverse Effects of Synthetic Cannabinoids: A Case-Oriented Review

*Susan M. Gurney, PhD**, Drexel University, Dept of Biology, 3245 Chestnut Street, PISB, Philadelphia, PA; *Karen S. Scott, PhD*, Arcadia University, 450 S Easton Road, Glenside, PA 19038; *Sherri L. Kacinko, PhD*, 3701 Welsh Road, Willow Grove, PA 19090; *Brandon C. Presley, BS*, NMS Labs, 2300 Stratford Avenue, Willow Grove, PA 19090; and *Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090

After attending this presentation, attendees will be able to describe the adverse effects reported in humans who have taken synthetic cannabinoids.

This presentation will impact the forensic science community by providing a review of internationally reported cases. It will highlight the importance of performing quantitative analysis on synthetic cannabinoid samples in order to gain a full understanding of the effects of this class of drug and of the individual compounds.

The term “synthetic cannabinoids” refers to artificial substances which are intended to mimic the physiological effect of cannabis. A wide variety of such compounds have been developed, partly in an attempt to avoid the legal penalties associated with the manufacture, distribution, and use of cannabis. These drugs differ in their chemical composition and, therefore, also differ in their effects on humans and their likelihood of detection by toxicological methods. The scientific understanding of synthetic cannabinoid compounds is hampered by a lack of awareness of this variety and, in practical terms, it is important to be able to correlate observed clinical effects with their likely toxicological causes. The reports presented will include data from small (<11 people) and large (>168 people) populations without toxicology confirmation, in addition to reports with qualitative confirmation and reports with quantitative analysis.

Synthetic cannabinoid drugs were first produced for research purposes in 1980. Since then, synthetic cannabinoid drugs have been manufactured in clandestine laboratories internationally, and sold in the United States in the form of smoking mixtures. Common brands of synthetic cannabinoids have been marketed, including Spice and K2. The first report of synthetic cannabinoid drugs in the United States was in 2008, when a synthetic cannabinoid compound was found in botanical material. Since then, the popularity of synthetic cannabinoids use has increased, as has the number of compounds which have been developed. With these different compounds and new compounds emerging onto the market, it has been challenging for forensic toxicologists to identify the individual drugs and metabolites in samples. Without quantitation of these drugs, it is difficult to understand the true effects these drugs are having on the user. This is why reports which include this data and dose response information are beneficial to the understanding of the adverse effects of these drugs. The adverse-effect profile of these drugs has not been studied in humans, and only infrequently in animal models; thus, much of the information about their toxicity comes from emergency department treatment reports and forensic case studies.

Case reports have been published describing adverse effects including data collected from emergency department admissions, mental health admissions, and clinical and forensic case reports. The current state of knowledge of adverse effects, both clinical and forensic in humans, includes non-serious physiological effects similar to smoking marijuana, and adverse effects including kidney damage, pulmonary dysfunction, cardiovascular effects, central nervous system effects, seizures, and psychosis. Reports to date include samples which have single synthetic cannabinoid compounds and mixtures of multiple compounds. With so many different synthetic cannabinoid compounds emerging and on the market, it is challenging to determine if these adverse effects are associated with specific compounds or with the class of drug. There is growing toxicological and pharmacological evidence of impairment, psychosis, tissue injury, and isolated deaths attributable to this emerging class of drugs.

Designer Drugs, Synthetic Cannabinoids, Adverse Effects

K54 4-Methoxy- α -PVP: *In Silico* Metabolite Prediction, Assessment of Metabolic Stability With Human Liver Microsomes, and Metabolite Identification After Human Hepatocyte Incubation With High Resolution-Mass Spectrometry

Kayla N. Ellefsen, MS*, National Institute on Drug Abuse/NIH, Biomedical Research Center, Ste 200, Rm 05A721, Baltimore, MD 21224; Madeleine J. Swortwood, PhD, National Institute on Drug Abuse, 251 Bayview Boulevard, BRC 05A721, Baltimore, MD 21224; Ariane Wohlfarth, PhD, 251 Bayview Boulevard, Office 05A505, Baltimore, MD 21224; Marta Concheiro-Guisan, PhD, 251 Bayview Boulevard, Rm 05A729, Baltimore, MD 21224; and Marilyn A. Huestis, PhD, Chemistry & Drug Metabolism, Intramural Research, NIDA, NIH, 251 Bayview Boulevard, Rm 05A721, Baltimore, MD 21224

After attending this presentation, attendees will better understand different approaches of investigating metabolic pathways and of selecting potential 4-methoxy- α -PVP metabolites to be targeted in human specimens.

This presentation will impact the forensic science community by demonstrating the applicability of utilizing *in silico* software predictions and *in vitro* metabolism experiments to elucidate the metabolic profiles of these emerging novel psychoactive substances.

Introduction: Synthetic cathinones emerged on the designer drug market as popular “legal” alternatives to illicit drugs during the late 2000s and are marketed as “legal highs” not for human consumption to avoid regulation. These novel psychoactive substances are continuously developed to circumvent legislative and regulatory efforts. As such, limited pharmacological and toxicological information is available. Recently, 4-methoxy- α -PVP was identified for the first time in illegal products purchased in Japan in 2013.¹ No metabolism studies have been performed on this compound. Complete metabolic profiles are needed for these novel psychoactive substances to enable identification of their intake and to link adverse effects and educate the public about the dangers of these “designer drugs.”

Objectives: To evaluate *in silico* metabolism predictions, perform metabolic stability assessment with Human Liver Microsomes (HLM), and to identify metabolites after human hepatocyte incubation with High-Resolution Mass Spectrometry (HRMS) for 4-methoxy- α -PVP.

Methods: *In silico* predictions were performed with MetaSite software, which predicts metabolites based on enzyme-substrate recognition and site reactivity of the molecule. To investigate the kinetics of 4-methoxy- α -PVP, 1 μ M drug was incubated with 50-donor-pooled human liver microsomes at 0, 3, 8, 13, 20, 30, 45, and 60min. For the human hepatocyte experiments, 10 μ M drug was incubated at 37°C with pooled cryopreserved human hepatocytes at 0, 1, and 3h based on HLM half-life. Diclofenac also was incubated as a control for human hepatocyte functional viability. Chromatographic separation of HLM samples, diluted 1:100 with mobile phase A (0.1% formic acid in water), was achieved with an Accucore™ C18 column (2.6 μ m, 100mm x 2.1mm) with mobile phase A and B (0.1% formic acid in acetonitrile) within 20min. Hepatocyte samples were diluted 1:5 with mobile phase A, and separated utilizing a Synergi 4 Hydro-RP column (80A, 150mm x 2mm) within 30min. Data from HLM and human hepatocyte samples were collected with a Thermo Scientific™ QExactive™ high-resolution mass spectrometer, and analyzed by WebMetabase software-assisted data mining. HLM and hepatocyte data were acquired using a high-resolution, full-scan, data-dependent mass spectrometry method. In addition, hepatocytes were acquired with and without an inclusion list of predicted metabolites generated by MetaSite, and with an All-Ion-Fragmentation (AIF) mass spectrometry method to identify potential unexpected metabolites. Scans were thoroughly data mined with different data processing algorithms utilizing WebMetabase.

Results: 4-methoxy- α -PVP exhibited a long half-life of 79.7min in HLM, with an intrinsic clearance of 8.7 μ L/min x mg. In addition, this compound is predicted to be a low-clearance drug with an estimated human hepatic clearance of 8.2mL/min/kg. Based on the structure of this synthetic cathinone and the results obtained, the following biotransformations were proposed: O-demethylation, aliphatic ring hydroxylation, ketone reduction, iminium formation, pyrrolidine ring hydroxylation followed by dehydrogenation of the corresponding lactam, pyrrolidine ring opening followed by oxidation to carboxylic acid, iminium formation and aliphatic hydroxylation, dihydroxylation, ketone reduction and O-demethylation, and ketone reduction and hydroxylation. The most dominant metabolite in the HLM and human hepatocyte samples was 4-hydroxy- α -PVP, also predicted *in silico*.

Conclusions: These are the first data identifying 4-methoxy- α -PVP metabolites that could document drug intake for forensic and clinical investigations. It is necessary to elucidate the metabolic pathways of these new psychoactive substances to enable linkage to adverse effects and document 4-hydroxy- α -PVP intake. This presentation will impact the forensic science community by demonstrating the applicability of utilizing *in silico* software predictions, and *in vitro* metabolism experiments to elucidate the metabolic profiles of these emerging novel psychoactive substances.

4-Methoxy-A-PVP, In Silico Prediction, In Vitro Metabolism

K55 Identification of Major Metabolites in Human Blood and Urine Associated With the Ingestion of Alpha-Pyrrolidinopentiophenone (Alpha PVP)

Melissa Friscia, MSFS, 429 Grand Avenue, Langhorne, PA 19047; Sarah E. Wolf, 18527 Woodard Road, Watertown, NY 13601; Amanda L.A. Mohr, MSFS, Center for Forensic Science, Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Francis X. Diamond, BS, 3701 Welsh Road, Willow Grove, PA 19090; Jillian K. Yeakel, MS, 3864 Courtney Street, Ste 150, Bethlehem, PA 18017; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will be able to identify the metabolic profile associated with use of alpha-PVP and identify its major metabolites. Attendees will be able to describe the process of using human liver microsomal incubations to verify the identity of novel drug metabolites.

This presentation will impact the forensic science community by providing an example of the use of various laboratory-based analytical and *in vitro* tools for metabolite identification of Novel Psychoactive Substances (NPS).

The purpose of this project was to collect biological samples from volunteers attending Electronic Dance Music (EDM) festival and evaluate samples for emerging NPS. Blood samples screening positive for alpha-PVP were further investigated for the presence of potential metabolites that had been produced *in vitro* using Human Liver Microsomes (HLM).

Alpha-PVP is an emerging novel psychoactive substance of the pyrrolidinophenone family, which has been identified in forensic casework samples over the last three years. Limited data exists on the mechanisms of action of alpha-PVP; however, it is believed to produce similar effects to Methylenedioxypyrovalerone (MDPV), which acts as a norepinephrine-dopamine reuptake inhibitor, producing stimulant-like effects and euphoria. Its metabolic profile has been investigated in a rat model with analysis of the urine by Gas Chromatography/Mass Spectrometry (GC/MS); however, there have been no reports of its metabolism in humans.

The analysis of several urine specimens found to contain alpha-PVP also disclosed the presence of other compounds with similar mass spectral characteristics. This prompted the investigation of the identity of these compounds to verify their origin as alpha-PVP metabolites. Several tools including High Resolution Accurate Mass Spectrometry (HRAMS) on a Liquid Chromatograph/Quadrupole/Time-Of-Flight/Mass Spectrometer (LC/Q/TOF), Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), GC-MS, and comparison of the profile of authentic human urine specimens from drug users with analysis of the products of incubation of the parent compound with a human liver microsome preparation were used to identify the metabolites.

Metabolites of alpha-PVP were produced by incubating a solution of alpha-PVP with pooled HLM. Phosphate buffer (pH 7.4) was spiked with 5,000ng of alpha-PVP. NADPH, a co-factor for the enzymatic reaction, was added to the buffer solution and allowed to incubate for two hours at 37°C. Following filtration, the samples were analyzed using LC/Q/TOF to generate exact mass data. Incubated samples were compared with controls that were incubated without the essential NADPH co-factor to help identify products of metabolism.

Authentic human blood samples from cases in which paired urine samples had tested positive for alpha-PVP were extracted using a basic liquid-liquid extraction using 0.1M borate buffer (pH=10.4) into n-butyl chloride and ethyl acetate. The organic phase was evaporated to dryness and reconstituted in 90:10 5mM ammonium formate and 0.1% formic acid in acetonitrile and analyzed using LC/Q/TOF.

Human blood and urine samples that had screened positive for alpha-PVP by LC/Q/TOF were further examined using extracted ion chromatograms for the exact masses of potential metabolites produced using the HLM incubation procedure described above.

One of the major alpha-PVP metabolite candidates from the HLM experiments had a retention time and accurate mass (246.1645g/mol) equivalent to $C_{15}H_{21}NO_2$, which is consistent with methoxetamine, an unrelated NPS compound with dissociative anesthetic properties; however, the fragment ions in the high energy mass spectra were not consistent with those present in the methoxetamine standard.

The identity of the apparent alpha-PVP metabolite was established as resulting from hydroxylation of the side chain on alpha-PVP (Figure 1). Using structural elucidation tools with the metabolite structure, possible fragmentation patterns were suggested by the software, based upon the ions seen in the high energy mass spectra. Three of the fragments proposed from the software were found in the high energy mass spectra, confirming its identity as a hydroxylated metabolite of alpha-PVP.

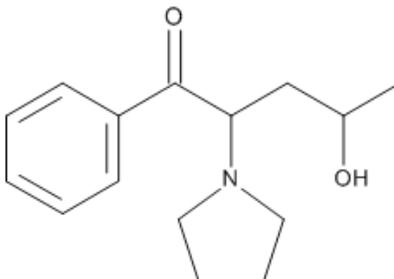

Figure 1

The combined results from analysis of mass spectrometric data, HLM incubations, and analysis of urine and blood from authentic cases of alpha-PVP ingestion allowed identification of several major metabolites in humans, several of which were consistent with results from published rat metabolic profiles; in addition other previously unknown metabolites were identified.

Alpha-PVP, Metabolism, Novel Psychoactive Substances

K56 Characterization of AB-FUBINACA Metabolites in Rat Urine by Liquid Chromatography/Time-of-Flight/Mass Spectrometry (LC/TOF/MS)

Ashraf Mozayani, PharmD, PhD*, Texas Southern University, 3100 Cleburne Avenue, Houston, TX 77004; Aybike Dip, PhD, Texas Southern University, 3100 Cleburne, Houston, TX 77004; Hsinhung Chen, 2400 N Braeswood Boulevard, #204, Houston, TX 77030; Amruthesh Shivachar, PhD, Texas Southern University, 3100 Cleburne, Houston, TX 7700; Munder Zagaar, PhD, Texas Southern University, 3100 Cleburne, Houston, TX 77004; and Jeffrey Walterscheid, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054

After attending this presentation, attendees will better understand the synthetic cannabinoid receptor agonist AB-FUBINACA and its metabolites in the rat model. Since it is a relatively new and potent drug that remains largely uncharacterized, this study is an important step in elucidating oxidative metabolites as targets for revised screening assays in forensic casework.

This presentation impacts the forensic science community by increasing awareness of the *in vivo* metabolites of AB-FUBINACA as determined by LC/TOF/MS analysis. The knowledge gained will help to improve detection capabilities and practices.

Synthetic cannabinoids were first produced by academic and pharmaceutical laboratories with the hope of providing therapeutic pain relief without the toxicity that accompanies chronic opiate use. While many of these drug derivatives were published in the medical literature, others were merely patented. These stale patented recipes have become the basis for a new generation of illicit drug manufacture, replacing the first generation JWH species. AB-FUBINACA is one of the newest synthetic cannabinoids introduced in the past several years, first detected in blended synthetic products in 2012.¹ Because of its potency and obscurity, little is known about the metabolism or pharmacology of these substances.

In order to study the metabolic fate of AB-FUBINACA, the Wistar rat model was utilized to deliver drugs by intraperitoneal injections and then urine was collected for analysis. Rats weighing from 160g to 200g were housed in a temperature- and humidity-controlled room with a 12-hour light/dark cycle. After acclimatization, the rats were transferred to individual metabolic cages for the course of the experiment, to collect urine. Injections consisted of 5mg/kg of AB-FUBINACA dissolved in dimethyl sulfoxide, which were repeated daily for five days. The control group (n=3) received dimethyl sulfoxide injections, while the experimental group (n=5) received the dissolved drug. Urine samples were collected every day at the same time during injection and refrigerated until preparation for analysis.

Extractions were performed by combining 0.2mL of urine with an organic mixture of 1:1 isopropanol/1-chlorobutane, fortified with saturated magnesium sulfate and adjusted to pH 10 with ammonium hydroxide. After vortexing and centrifuging, the organic layer was removed to a fresh vial where the extract was evaporated to a residue with compressed nitrogen gas. The residue was reconstituted with mobile phase buffer and injected for LC/TOF/MS scanning. Examination of the time-of-flight data showed possible hydroxyl metabolites at 385.1687m/z, in comparison to the parent mass of 369.1721m/z. While the position of the hydroxyl addition on the molecule is unclear, the accurate mass and retention is now known for successful library matching.

Other published articles have studied metabolites of AB-FUBINACA in human liver microsomes, but this work is the first *in vivo* study to determine the metabolites of AB-FUBINACA in urine.² A putative hydroxyl metabolite of AB-FUBINACA was identified; however, a carboxyl metabolite has not been defined by this method.

Synthetic Cannabinoids, AB-FUBINACA, LC/TOF/MS

K57 Broad Detection of Synthetic Cannabinoids in Whole Blood Using Ultra High-Performance Liquid Chromatography-Quadrupole-Time-of-Flight (UHPLC-Q-TOF)

Robert Kronstrand, PhD, National Board of Forensic Medicine, Dept of Forensic Toxicology, Artillerigatan 12, Linköping SE 587 58, SWEDEN; Cassandra Jaque, BSc, National Board of Forensic Medicine, Artillerigatan 12, Linköping SE 587 58, SWEDEN; and Markus Roman, BS, National Board of Forensic Medicine, Dept of Forensic Genetics and Forensic Toxicology, Artillerigatan 12, Linköping SE 587 58, SWEDEN*

After attending this presentation, attendees will understand the challenges associated with the analysis of synthetic cannabinoids and be able to describe the current panorama of these drugs.

This presentation will impact the forensic science community by increasing awareness of the need to analyze for synthetic cannabinoids in cases of both the living and the deceased.

Synthetic cannabinoids are the most prevalent group of new psychoactive substances emerging on the illicit market. The changes in availability from internet sites are partly a result of legislation where substances becoming scheduled are replaced by new compounds. Therefore, it is a challenge to keep methods up to date. This study was performed to create a strategy for the analysis of a broad range of synthetic cannabinoids that was flexible and to which one could easily add new compounds as they appear on the market and subsequently in the toxicological samples received.

Blood samples (1.0g) were prepared by liquid-liquid extraction with diethylether at pH 10.2. An in-house library comprising full Tandem Mass Spectrometry (MS/MS) spectra of 75 synthetic cannabinoids was built by analyzing solutions from certified standards. Identification was based on retention time, accurate mass, isotopic pattern and MS/MS spectra. Analyses was performed on an Agilent® 6550 iFunnel Q-TOF Liquid Chromatography/Mass Spectrometry (LC/MS) system combined with a 1290 Infinity® LC system. Ions were generated in positive electrospray ionization mode and were detected by data dependent acquisition MS/MS. Separation was achieved by gradient chromatography on an YMC Triart-C18 column within 8.5 minutes. Mobile phase A consisted of 0.05 % formic acid in 10mM ammonium formate and phase B of 100 % methanol.

The method was validated accordingly to guidelines for qualitative methods including selectivity, matrix effects, extraction recovery, response variation and spectra score variation at the threshold concentration, and stability in matrix. The selectivity was excellent; however, the analyte response was affected by the matrix with 28 of the 75 analytes presenting with matrix effects above 25%. Still, the variation in response and spectra scores was less than 15% at the thresholds chosen. Sixty-six analytes obtained a threshold of 100pg/g and seven analytes 200pg/g whole blood. All analytes except AM-2201 were stable when refrigerated for two weeks. After four weeks refrigeration, JWH-122 and UR-144 also showed a decrease of more than 20%.

The method was applied to cases including petty drug offences, DUID, violent crimes, and autopsies where analysis of synthetic cannabinoids was requested. In total, 442 samples were run during the first two months in routine with a positive rate of 24% resulting in the detection of 14 different parent compounds. The most prevalent compound was AB-FUBINACA (N=78) followed by AB-PINACA (N=12), BB-22 (N=10), 5F-NNEI (N=7), FUB-PB22 (N=5), 5F-PB22 (N=4), THJ2201 (N=4), 5F-AKB48 (N=3), 5F-AB-PINACA (N=2), NNEI (N=2), and one finding each of STS-135, PB22, FDU-PB22, and UR-144.

Blood as a matrix was chosen because of the better availability of parent compounds rather than metabolites from certified suppliers. A qualitative approach was chosen to simplify validation and inclusion of new analytes. High-resolution mass spectrometry with UHPLC was chosen to increase both the chromatographic and mass spectral selectivity. In conclusion, the strategy provided a sensitive, flexible, end-point method that detects parent compounds, simplifying prosecution in cases where the intake of a scheduled drug is the charge. A disadvantage of the qualitative approach is that it does not allow for a detailed interpretation; however, the pharmacodynamics of synthetic cannabinoids is largely unknown and a concentration does not necessarily increase the interpretation power.

Synthetic Cannabinoids, Whole Blood, TOF/MS

K58 Sleeping With the Enemy: Zolpidem in Driving Under the Influence (DUI) and Postmortem Cases

Charlotte A. Baker, PhD, 1885 Old Spanish Trail, Houston, TX 77584*

After attending this presentation, attendees will better understand the pharmacokinetic properties that contribute to the therapeutic benefits of zolpidem (Ambien®), the toxicological findings in blood specimens, and zolpidem's potential impact on DUI and medicolegal investigations encountered by the Harris County Institute of Forensic Sciences. In addition to the reported findings and influence of zolpidem use in Harris County, its prevalence in the mainstream media will also be discussed.

This presentation will impact the forensic science community by describing the mechanistic properties, therapeutic benefits, and Food and Drug Administration (FDA) -established regimen guidelines of zolpidem, as well as disclosing the potentially deleterious effects of improper usage as determined by toxicological findings from casework investigations.

Zolpidem was approved by the FDA in 1992 and has become a common drug to aid with insomnia but it has recently gained attention for potential dangerous side effects of sleep walking, abnormal thinking, sleep driving, and residual effects into the morning. Zolpidem is a short-acting sedative-hypnotic prescribed for the short-term treatment of insomnia and works by activating the neurotransmitter GABA by a mechanistically similar manner as the benzodiazepines such as Xanax® and Valium®. It is typically prescribed as 5mg or 10mg capsules for immediate release and 6.25mg to 12.5mg for extended-release products (Ambien® CR). This medication is known to contribute to sleepiness the day after ingestion and is dependent on drug dose and individual characteristics. Therefore, it is recommended that the patient has at least eight hours of sleep to ensure that the drug is fully metabolized due to morning impairment. To further address the concern, the United States Food and Drug Administration approved a dose reduction in 2013, reducing the recommended dose of long-lasting impairment from 10mg to 5mg, depending on each individual.

Zolpidem has been depicted as a controversial sleeping aid since its long-lasting effects on patients have surfaced revealing abnormal behaviors due to its consumption. Previously, these abnormal behaviors were attributed to the combination effects with alcohol; however, there has been a growing revelation that these behaviors are induced with just zolpidem taken alone. Furthermore, there has been a growing concern on the evaluation of driving impairment with the use of zolpidem and motor vehicle accidents due to the increase of drugged driving cases. Finally, there has also been a significant increase in deaths from ingesting zolpidem in combination with other drugs and/or ethanol.

Harris County has received 136 cases from 2012-2014 that were positive for zolpidem. Several cases will be discussed related to zolpidem in DUIs and deaths that have resulted, including cases that have been highlighted in the media, as well as cases analyzed by the Harris County Toxicology Laboratory. In this presentation, several cases will be discussed related to DUI and postmortem cases.

Case 1: A 26-year old Asian male was driving under the influence. Upon analysis, zolpidem was found in the blood at a concentration of 1.0mg/L.

Case 2: A 63-year-old White male was driving under the influence with a blood level of 0.99mg/L for zolpidem. Ethanol was also detected at 0.01g/100mL which is below the level of impairment. Although norcarboxytetrahydrocannabinol was detected at 16ug/L, (the inactive metabolite of THC) it is not considered to have contributed to any level of impairment.

Case 3: A 54-year-old Black male was found dead in his home, apparently the victim of a suicide. Zolpidem was analyzed at a concentration of 1.4mg/L. Tramadol and desmethyltramadol were found in his blood sample at concentration levels of 17mg/L and 0.54mg/L, respectively.

Other cases that have gained national media attention will also be presented.

Zolpidem, DUI, Postmortem

K59 Pyrimethamine Toxicity: A Case Report

Steven Marcus, MD, Rutgers, New Jersey Medical School, 140 Bergen Street, Newark, NJ 07103; Numan Butt, MD, Rutgers, New Jersey Medical School, 185 S Orange Avenue, Newark, NJ 07103; and Sherri L. Kacinko, PhD, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will understand the pharmacology and toxicology of pyrimethamine.

This presentation will impact the forensic science community by offering a description of the analysis of biological and non-biological material for pyrimethamine, a drug not normally encountered in routine forensic casework. In addition, a brief review of published cases involving pyrimethamine toxicity and a case report of an infant showing symptoms of pyrimethamine toxicity will be provided.

Pyrimethamine (PYR) is an antiparasitic medication used for treatment of protozoal infections including toxoplasmosis. The recommended dose for treatment of congenital toxoplasmosis is 1mg/kg/day for two to four days, then 0.5mg/kg/day for one month. Peak plasma concentrations following doses of 0.5-2mg/kg/day were 0.29-2.2mcg/mL with half-lives of 2.7-5.2 days. Plasma concentrations in previously reported cases involving toxicity in infants were 1.5, 6.2, and 13.0mcg/mL. Adverse effects associated with pyrimethamine treatment include anorexia, rash, and hematological disorders including bone marrow depression. Concurrent administration of folic acid has been used to minimize the risk of reversal neutropenia that has been noted in infants undergoing pyrimethamine treatment. PYR toxicity characterized by neurological hyper-excitability, seizure, and gastrointestinal symptoms has rarely been reported.

In this case, a five-month-old male child, on therapy for congenital toxoplasmosis complicated by chorioretinitis, developed irritability and was seen in an emergency room and discharged after receiving a single dose of PYR. Shortly after a second dose, he developed irritability and suffered a tonic-clonic seizure. The seizure responded to lorazepam administration and he was admitted to the hospital. PYR was stopped for 24 hours and no seizures were noted. Upon re-introduction of the medication from the same dispensed bottle, the child suffered another seizure. Serum samples collected 18 hours, 4 days, and 11 days after last exposure were analyzed for pyrimethamine along with the liquid medication used to treat the infant.

PYR was quantified in serum using a validated assay. Samples underwent a three-step liquid-liquid extraction, and then were dried, reconstituted in toluene, and derivatized with butyric anhydride. Samples were then injected on the gas chromatograph with a nitrogen phosphorus detector and separated on a DB-17 capillary column (15m x 0.32mm I.D., 0.15µm film) using a temperature gradient and constant gas flow. The serum specimen, collected ~18 hours after the last dose, contained 3.8mcg/mL PYR. Four days later, PYR concentration had dropped to 1.2mcg/mL and 11 days post-exposure the PYR was below the reporting limit of the assay (0.2mcg/mL). The liquid medication, which was supposed to contain 2mg/mL PYR, was determined to have a concentration of 94mg/mL. Based on the calculated concentration in the medication the infant received, approximately 280mg of PYR instead of 6mg ((based on the prescribed dose of 3mL of a 2mg/mL solution). Despite the long half-life of PYR, it can still be assumed that the peak concentration of PYR would have been achieved well before this serum was collected so it would have been greater than 3.8mcg/mL and in the range of previously reported toxicities. The concentration of 1.2mcg/mL four days later is consistent with the reported half-life of PYR.

Pyrimethamine, Pediatric, Toxicology

K60 Ethyl Glucuronide, Ethyl Sulfate, and Nicotine and Metabolites Quantified in Human Fetal Liver From Electively Terminated Pregnancies

Sarah K. Himes, BS, NIDA, 251 Bayview Boulevard, Ste 200, Rm 05A721, Baltimore, MD 21224; Karl B. Scheidweiler, PhD, NIDA-IRP, NIH, 251 Bayview Boulevard, Ste 200, Rm 05A729, Baltimore, MD 21224; Susan Fairley, PhD, University of Aberdeen, Institute of Medical Sciences, Division of Applied Medicine, Foresterhill, United Kingdom AB25 2ZD, SCOTLAND; Panagiotti Filis, PhD, University of Aberdeen, Institute of Medical Sciences, Division of Applied Medicine, Foresterhill, SCOTLAND; Alex Douglas, PhD, University of Aberdeen, Institute of Medical Sciences, Division of Applied Medicine, Foresterhill, SCOTLAND; Peter J. O'Shaughnessy, PhD, University of Glasgow, College of Medical Veterinary and Life Sciences, IBAHCM, Glasgow, Lanarkshire G61 1QH, SCOTLAND; John P. Iredale, MD, PhD, University of Edinburgh, MRC Centre for Inflammation Research, Edinburgh, SCOTLAND; David Hay, PhD, University of Edinburgh, MRC Centre for Regenerative Medicine, Edinburgh, SCOTLAND; Paul A. Fowler, PhD, University of Aberdeen, Institute of Medical Sciences, Division of Applied Medicine, Foresterhill AB25 2ZD, UNITED KINGDOM; and Marilyn A. Huestis, PhD*, Chemistry & Drug Metabolism, Intramural Research, NIDA, NIH, 251 Bayview Boulevard, Rm 05A721, Baltimore, MD 21224

After attending this presentation, attendees will be able to describe a simultaneous human fetal liver sample preparation and two Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) quantification methods for hepatic alcohol and tobacco markers. Method validation data and results for eight alcohol and nicotine markers in 118 fetal livers will be presented.

This presentation will impact the forensic science community by providing fetal liver alcohol and, for the first time, tobacco concentrations to document *in utero* exposure and potential related exposure toxicities.

Introduction: Adult health is partly programmed during fetal development. Fetal exposure to tobacco, alcohol, and other drugs alters normal hormone regulation and early development, possibly leading to maladaptations and contributing to adult metabolic syndromes. Mechanisms through which fetal drug exposures result in reduced adult health are poorly understood. The objective was to develop quantitative alcohol and tobacco marker assays for human fetal liver to further laboratory research on fetal endocrine disruption.

Methods: Blank liver (0.25g) was fortified with deuterated internal standards. Samples were bead beater homogenized in methanol 0.01% formic acid and passed through a 10 μ m reservoir filter. Two filtered liver supernatant portions were aliquoted into separate tubes for supported liquid extraction of nicotine and metabolites and anion-exchange solid phase extraction for Ethyl Glucuronide (EtG) and Ethyl Sulfate (EtS). An AB SCIEX™ 5500 Qtrap® mass spectrometer was interfaced with a Shimadzu® UFLCXR system for analysis with gradient chromatographic separation of nicotine, cotinine, 3-*trans*-hydroxycotinine (OHCOT), nicotine-N-glucuronide (NG), cotinine-N-glucuronide (CG), and OHCOT-O-glucuronide (OHCOT-G) on an Agilent® Poroshell 120 EC-C8 column (150 x 2.1mm, 2.7 μ m). Liver EtG and EtS were separated on a Phenomenex® Kinetex® XB-C18 (100 x 2.1mm, 2.6 μ m) column. Sensitivity, specificity, linearity, accuracy, imprecision, extraction efficiency, matrix effect, carryover, dilution integrity, and stability were evaluated during method validation. Human fetal liver samples (n=118) from normally progressing, electively terminated pregnancies (11-21 weeks gestation) were analyzed.

Results: Linear ranges were 1-300 (cotinine), 5-1500 (CG, nicotine, EtS), 2.5-750 (NG and OHCOT), 10-2,000 (OHCOT-G), and 20-3,000ng/g (EtG). Calibration employed 1/x² weighting (correlation coefficients ≥ 0.989). Extraction efficiencies were 72%-87% (EtG and EtS), 80%-94% (nicotine, cotinine, and OHCOT), and 53%-71% (NG, CG, and OHCOT-G). Matrix suppression for all analytes was 17.5%-57.3%, except CG (11%-12.3% enhancement). Overall accuracy was 84.2%-115.4% for all analytes at three Quality Control (QC) concentrations across the linear range; between-run imprecision (%CV) was 3.5%-9.4% (n=20). Five unique negative liver samples had no interfering peaks. None of 90 potential exogenous interferences fortified at 4,000ng/g into low QC samples interfered. No carryover was detected at 1.6 times the upper LOQ. Analytes were stable ($\leq 19\%$ change) after 72h on a 4°C autosampler, for 16h at room temperature, 72 h at 4°C, and three freeze-thaw cycles, and in filtered liver supernatants for five days at 4°C. Of 118 authentic human fetal liver samples, 11% were EtG-positive, 72% EtS-positive, 80% cotinine-positive, 64% OHCOT-positive, 59% nicotine-positive, and 31%-68% positive for nicotine glucuronide metabolites. All EtG-positive samples were also EtS-positive, with EtG concentrations always greater (1.6-4.9 times) than EtS; of 13 samples positive for both, 10 were positive for tobacco markers. In EtS-only positive samples, 78% were positive for tobacco markers. In 33 alcohol-negative samples, 28 were positive for tobacco markers.

Toxicology Section - 2015

Conclusions: The novel bead beater homogenization method with separate sample clean-up and chromatographic methods for acidic EtG and EtS and basic nicotine and metabolites provided accurate quantification in a single 0.25g liver sample. Investigators needing to quantify *in utero* alcohol and tobacco exposure in human fetal liver will find this method simple, effective, and highly reproducible. Fetal liver EtG is most likely of maternal origin, as EtG readily crosses the placenta and fetal glucuronidation capacity is limited. Fetal liver EtS may be from maternal and fetal origin, as this analyte likely crosses the placenta and fetal sulfotransferase activity is variable and significant. These data impact the forensic science community by providing fetal liver alcohol and, for the first time, tobacco concentrations, to document *in utero* exposure, and potential related exposure 1 toxicities.

Supported by the Intramural Research Program, National Institute on Drug Abuse, National Institutes of Health, and Medical Research Council (UK) grant MR/L01 0011/1. The collection of fetal liver material was approved by the National Health Service Grampian Research Ethics Committees (REC04/S0802/21).

Fetal Liver, Ethyl Glucuronide, Nicotine

K61 The Egg Roll Driving Under the Influence (DUI) Defense: A Unique DUI Defense Incorporating Slow Gastric Emptying Due to the Presence of Egg Rolls, Followed by Rapid Gastric Emptying Due to Vehicle-Collision Impact

Deborah R. Stonebarger, BS, Department of Justice, Redding Laboratory, 9737 Tanqueray Court, Redding, CA 96003*

After attending this presentation, attendees will understand a unique DUI defense put forth in a California Supreme Court, and how the criminalist and prosecution team contended with the issues. Attendees will learn more about how the concepts of tolerance and perception of impairment can be used to influence the jury. Attendees will also better understand some unusual legal aspects and challenges at a DUI trial, including: (1) a granted motion to compel the defense to discover to the prosecution; (2) the presence of the criminalist throughout the duration of the trial; (3) an attempt to impeach the criminalist on the stand; and, (4) information about the verdict, sentencing, and “reconsideration” of the sentence by the court.

This presentation will impact the forensic science community by creating an awareness of a unique DUI defense; it will also educate the forensic science community with regard to challenges and lessons in DUI courtroom testimony.

After attending a holiday social gathering on December 21, 2012, where he had been eating and drinking, the defendant, Coulter Mann, was traveling northbound on Highway 101 in far northern California. At approximately 8:54 p.m., and at the moment of receiving a cell phone call, the defendant drifted into the southbound lane of Highway 101, causing a fatal head-on collision with the driver traveling south. Due to the condition of the defendant’s vehicle after the collision, he had to be extricated from the vehicle and transported to a local hospital for emergency treatment. He arrived at the hospital at approximately 10:00 p.m. His legal blood draw occurred at 10:55 p.m. and the results were 0.20 grams/100 milliliters.

The defendant was an assistant principal at a local middle school and was a very well-liked and well-respected member of the community, as was his entire family. The defense team included two attorneys, one of which was the defendant’s father, and a toxicology expert. During trial in January of 2014, the defense’s theory was that the defendant was not impaired at the time of driving, and that the cell phone call was the sole cause of the collision. The defendant had admitted to drinking 35-40 ounces of an 8.8% beer plus two to three 12-ounce bottles of a 6% beer over the course of approximately four hours, except that he had finished two-thirds of his last bottle of beer shortly before he left the gathering. While drinking the beer, he also consumed some appetizer-type food. Of specific interest to the defense was that the defendant had consumed six to seven egg rolls just prior to arriving at his social gathering. According to the defense, the multitude of ingredients in the egg rolls delayed the defendant’s absorption of ethanol to the point that he was not at or above a 0.08 grams/100 milliliters blood alcohol concentration at the time of the collision; therefore, he was not impaired for driving purposes. While administering first aid at the scene of the collision, an ambulance driver did not note that the defendant had signs of impairment nor did they note an odor of alcohol from his breath. The California Highway Patrol officer that responded to the scene did not make note of an odor of alcohol on the defendant’s breath. The emergency room physician did not note any signs of impairment, including no observed horizontal gaze nystagmus, while she treated the defendant. A blood chemistry laboratory panel performed at the hospital approximately one-half hour prior to the legal blood draw indicated the presence of ethanol. When the California Highway Patrol was able to leave the scene of the collision and go to the hospital to obtain a statement from the defendant, he noticed a strong odor of alcohol emanating from the defendant and eventually obtained a legal blood draw for DUI purposes. The only injuries sustained by the defendant were a broken ankle and an approximate 5mm abrasion to his spleen. All other systems, including gastrointestinal, were within normal limits. While the defense did not offer specific absorption or elimination rates, they opined that the impact of the collision, as demonstrated by the laceration to the spleen, forced unabsorbed food and ethanol into the small intestine where the ethanol became rapidly absorbed by the time the legal blood draw occurred at the hospital.

DUI Impairment, Alcohol Pharmacokinetics, Courtroom Testimony

K62 Determination of Gamma-Hydroxybutyric Acid (GHB) in Hair Using Alternative Derivatization Techniques

Brittany M. Watt, BA, 651 Brooke Road, Apt D44, Glenside, PA 19038; Edward J. Barbieri, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Melissa Frisica, MSFS, Center for Forensic Science Research and Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will better understand a new method of derivatization for improved separation of GHB and urea in hair samples, following methanolic incubation, by Gas Chromatography/Mass Spectrometry (GC/MS). Attendees will also be provided with an overview of the effects of external factors such as diet, drug use, etc., on the levels of endogenous GHB in human hair.

This presentation will impact the forensic science community by providing information about an alternative derivatization technique which allows for better separation of silylated GHB and urea in hair than what is currently achieved by using N,O-Bis(trimethylsilyl) Trifluoroacetamide (BSTFA) as a derivatizing agent.

GHB is an important forensic drug due to its potential for abuse and its implication in drug-facilitated crimes; however, it is also an endogenous compound and is therefore found in low concentrations in human hair. GHB is only detectable in blood and urine samples for up to 12 hours. Therefore, in cases of suspected GHB use, hair can be used as an alternative matrix. When analyzing hair samples for GHB, the most commonly used derivatization reagent is BSTFA with 1% Trimethylchlorosilane (TMCS). One issue that is commonly encountered using BSTFA is the incomplete separation of GHB and urea by GC/MS.

Derivatization with BSTFA is a suitable method when analyzing hair samples by Two-Dimensional Gas Chromatography/Time-of-Flight/Mass Spectrometry (GCxGC/TOF/MS) or by Gas Chromatography/Tandem Mass Spectrometry (GC/MS/MS), which are both able to sufficiently separate GHB and urea, but most forensic laboratories do not have access to this instrumentation. Therefore, an alternative method of derivatization is needed which will allow for better separation by GC/MS. The following derivatization reagents were analyzed for their ability to separate GHB and urea: BSTFA with 1% TMCS, N-methyl-N(tert-butyl)dimethylsilyl trifluoroacetamide (MTBSTFA) with 1% tert-butyl)dimethylchlorosilane (TBDMCS), boron trifluoride (BF₃) in methanol, pentafluorobenzyl bromide (PFBBBr), and pentafluoropropionic acid anhydride (PFPA). MTBSTFA was found to yield enhanced separation compared to BSTFA. The alkylation and acylation reagents, BF₃, PFBBBr, and PFPA, were not found to sufficiently derivatize GHB or urea for GC/MS analysis.

The determined method of derivatizing with MTBSTFA was used to analyze hair samples collected from volunteers in a university community (students, faculty, and staff). Each participant answered questions about their diet, hair treatments, personal life, and drug and alcohol use. For each sample, the provided answers were compared to the detected GHB concentrations in order to determine any effect of the external factors on endogenous GHB concentrations. Concentrations were between 0.2ng/mg and 1.0ng/mg. Some outliers were detected, indicating possible links between diet, lifestyle, hair treatment, and GHB concentration.

GHB, Derivatization, GC/MS

K63 Cannabinoid Disposition in Oral Fluid After Controlled Cannabis Vaporizer Administration

Rebecca L. Hartman, BA*, 251 Bayview Boulevard, Ste 200, Rm 05A721, Baltimore, MD 21224; Moonhee Jang, PhD, National Forensic Service, 331-1 Sinwol-7-dong, Yangcheon-gu, Seoul 158-707, SOUTH KOREA; Andrew L. Spurgin, PharmD, National Advanced Driving Simulator, 2401 Oakdale Boulevard, Iowa City, IA 52242; Keming Yun, PhD, Shanxi Medical University, School of Forensic Medicine, 56 Xinjian South Street, Taiyuan, Shanxi, CHINA; David A. Gorelick, MD, PhD, University of Maryland, Dept of Psychiatry, PO Box 21247, MPRC-Tawes Bldg, Baltimore, MD 21228; Gary Milavetz, PharmD, University of Iowa, College of Pharmacy, S419 PHAR, 115 Grand Avenue, Iowa City, IA 52242; Timothy L. Brown, PhD, University of Iowa, National Advanced Driving Simulator, 2401 Oakdale Boulevard, Iowa City, IA 52242; Gary Gaffney, MD, University of Iowa, Carver College of Medicine, 1874 John Pappajohn Pavilion, Iowa City, IA 52242; and Marilyn A. Huestis, PhD, Chemistry & Drug Metabolism, Intramural Research, NIDA, NIH, 251 Bayview Boulevard, Rm 05A721, Baltimore, MD 21224

After attending this presentation, attendees will better understand cannabinoid disposition in Oral Fluid (OF) following cannabis vaporization.

This presentation will impact the forensic science community by providing a framework for interpreting OF cannabinoid concentrations after vaporization.

Background: Cannabis is the most prevalent illicit drug worldwide. OF is an advantageous sampling matrix for drug screening due to ease of observed collection, non-invasiveness, and ability to collect and analyze onsite. Limited data exist for cannabinoid disposition following vaporization, a common alternative to smoking.

Hypothesis: OF THC, CBD, and CBN maximum concentrations will occur immediately post-inhalation and decrease rapidly. CBD and CBN will appear in lower concentrations than THC. When THCCOOH is detected, it will be in low concentrations, with maximum concentration later in the time course.

Methods: Current occasional ($\geq 1x$ /last 3 months, ≤ 3 days/wk) cannabis smokers provided written informed consent and OF specimens for this Institutional Review Board-approved controlled cannabis administration study. Participants inhaled 500mg placebo, low (2.9%)- Δ^9 -tetrahydrocannabinol (THC), or high (6.7%)-THC cannabis in separate sessions in a randomized within-subject design. OF specimens were collected with the Quantisal™ collection device prior to and 0.17, 1.4, 2.3, 3.3, 4.3, 5.3, 6.3, 7.3, and 8.3h post-dose. Specimens were quantified for THC, 11-nor-9-carboxy-THC (THCCOOH), cannabidiol, and cannabinol (limits of quantification 0.5 μ g/L, 15ng/L, 1 μ g/L, and μ g/L, respectively). Maximum concentration (C_{max}), time to C_{max} (t_{max}), and time of last detection (t_{last}) were determined and area under the curve from baseline to 8.3h ($AUC_{0-8.3h}$) calculated by the linear trapezoidal method. Within-subjects medians were compared with the Wilcoxon Matched-Pairs Test.

Results: Median (range) C_{max} , t_{max} , t_{last} , and $AUC_{0-8.3h}$ from 28 participants (19M, 9F, ages 21-40 years) are presented in the table. Significant differences ($p < 0.05$) were detected ^aplacebo vs. low, ^bplacebo vs. high, and ^clow vs. high, as indicated.

		THC	THCCOOH	CBD	CBN
Placebo	C_{max} , μ g/L (ng/L, THCCOOH)	4.7 ^{a,b} (0-25.9)	0 ^{a,b} (0-361)	0 ^{a,b} (0-1.7)	0 ^{a,b} (0-1.9)
	t_{max} , h	0.17 (0.17-1.4)	2.3 (0.17- ≥ 8.3)	0.17 (0.17-0.17)	0.17 (0.17-0.17)
	t_{last} , h	6.3 ^{a,b} (1.4- ≥ 8.3)	≥ 8.3 (5.3- ≥ 8.3)	0.17 (0.17-0.17)	0.17 (0.17-0.17)
	$AUC_{0-8.3h}$, h* μ g/L (h*ng/L, THCCOOH)	6.6 ^{a,b} (0-56.1)	0 ^{a,b} (0-1941)	0 ^{a,b} (0-1.4)	0 ^{a,b} (0-1.39)

Toxicology Section - 2015

Low	C_{max} , $\mu\text{g/L}$ (ng/L, THCCOOH)	848 ^a (16.3-18230)	24.1 ^a (0-686)	6.0 ^{a,c} (0-100)	54.4 ^a (1.2-941)
	t_{max} , h	0.17 (0.17-0.17)	3.3 (0.17- \geq 8.3)	0.17 (0.17-0.17)	0.17 (0.17-0.17)
	t_{last} , h	\geq 8.3 ^a (2.3- \geq 8.3)	\geq 8.3 (0.17- \geq 8.3)	0.17 ^c (0.17-2.3)	2.3 (0.17-7.3)
	AUC _{0-8.3h} , h* $\mu\text{g/L}$ (h*ng/L, THCCOOH)	723 ^a (13.9-3865)	42.9 ^a (0-2935)	3.1 ^{a,c} (0-79.0)	44.1 ^a (0.85-246)
High	C_{max} , $\mu\text{g/L}$ (ng/L, THCCOOH)	862 ^b (25.1-23680)	18.6 ^b (0-464)	34.7 ^{b,c} (1-1106)	32 ^b (0-766)
	t_{max} , h	0.17 (0.17-3.3)	2.8 (0.17-6.3)	0.17 (0.17-3.3)	0.17 (0.17-3.3)
	t_{last} , h	\geq 8.3 ^b (6.3- \geq 8.3)	\geq 8.3 (0.17- \geq 8.3)	2.3 ^c (0.17- \geq 8.3)	2.3 (0.17- \geq 8.3)
	AUC _{0-8.3h} , h* $\mu\text{g/L}$ (h*ng/L, THCCOOH)	934 ^b (38.4-19090)	66.2 ^b (0-2181)	32.0 ^{b,c} (0.72-912)	28.9 ^b (0-617)

Conclusion: OF THC concentrations after vaporization are comparable to previously-published smoking data. THC, THCCOOH, and CBN did not show any statistically significant low vs. high dose differences, suggesting participants were able to titrate dose by adjusting inhalation topography, similar to smoking behavior. When present, OF THCCOOH has low concentrations compared to the other analytes; in some occasional smokers, THCCOOH was not detected in OF even after the high dose. OF THCCOOH (if detected) was suggested to help differentiate active vs. passive cannabis exposure. This presentation will impact the forensic community by providing a framework for interpreting OF cannabinoid concentrations after vaporization.

Research was supported by the NIDA/NIH Intramural Research Program, NHTSA, and ONDCP.

Cannabis, Vaporizer, Oral Fluid

K64 Case Report of a Death Involving the Designer Opioid MT-45 Raises the Spectre of Synthetic Opioids in Forensic Casework

*Donna M. Papsun, MS**, 607 S Olds Boulevard, Fairless, PA 19030; *Alison Krywanczyk, MD**, Fletcher Allen Health Care, D13 Stonehedge Drive, South Burlington, VT 05403; *James C. Vose, BA*, Vermont Forensic Laboratory, PO Box 47, Waterbury, VT 05676; *Elizabeth A. Bundock, MD, PhD*, Vermont OCME, 111 Colchester Avenue, Burlington, VT 05401; and *Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090

After attending this presentation, attendees will understand the increasing relevance of synthetic opiates in forensic toxicology and death investigation casework and learn about the use of Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for the detection and quantification of the synthetic opioid “MT-45.”

This presentation will impact the forensic science community by introducing the first known case of death due to use of the designer synthetic opioid MT-45, as well as by placing the toxicology results in the context of the autopsy findings, and by explaining the detection and quantification methods used.

Opiates always figure prominently among the most frequently encountered drugs in toxic deaths. Interpretation is often complex due to issues including therapeutic misadventure, tolerance, palliative care, drug-drug interactions, and recreational versus medical use. While the most frequently encountered opioids are morphine (as a therapeutic agent or heroin metabolite), oxycodone, hydromorphone, hydrocodone, and fentanyl, recently illicit “designer opioids” have begun to appear in forensic casework. These include deaths attributed to acetyl fentanyl, a synthetic analog of fentanyl which resulted in a series of deaths in Rhode Island, Louisiana, and North Carolina, and a report of the unrelated synthetic opiate agonist AH-7921, a research chemical linked to deaths in Sweden and the United States. Kratom, a Southeast Asian plant containing the drug mitragynine with opioid-like effects which is currently uncontrolled in the United States, has also been seen in deaths in combination with tramadol. Most recently, much media attention has been paid to “Krokodil” (desomorphine), a synthetic derivative of codeine, although no toxicologically confirmed cases have been documented in the United States. Reported is the first documented incident of a death following use of a novel designer opioid, MT-45 (1-cyclohexyl-4-[(1R)-1,2-diphenylethyl]-piperazine. MT-45 is a substituted 4-(1,2-diphenylethyl)piperazine which is chemically unrelated to other known opioid agonists. It has been demonstrated to have approximately 80% of the potency of morphine in animal studies and is currently uncontrolled in the United States.

The case involved a 35-year-old White male, with a known history of substance abuse, who had not been seen for two days prior to being found deceased. He appeared to have collapsed adjacent to his drug preparation area where a scale, spoon, pipe, lighter, and two packets of white powder were found (syringe not present). One packet tested positive for MT-45 and the other tested positive for etizolam, an illicit thienodiazepine with benzodiazepine-like properties. Neither drug is prescribed in the United States; further investigation determined the decedent had purchased these online from a Canadian company and had been doing so on a monthly basis for quite some time. Autopsy revealed cerebral edema, congested lungs, and a possible old injection site on the dorsum of the foot. The postmortem toxicology panel routinely requested came back positive for diphenhydramine 220ng/mL in whole blood (over-the-counter medication present at scene), while the urine was presumptively positive for benzodiazepines and cannabinoids.

The postmortem blood was subsequently analyzed for MT-45 using LC/MS/MS. Sample preparation involved liquid-liquid extraction following addition of ammonium hydroxide and an extraction solvent of n-butyl chloride and acetonitrile (4:1,v/v). The instrument was operated in positive electrospray, Multiple Reaction Monitoring (MRM) mode. The column used for separation was a BEH C18, 2.1 x 5.0mm with mobile phases of 0.1% formic acid in methanol and 0.1% formic acid in water. The internal standard reference was acetyl fentanyl D5. The transitions for acetyl fentanyl D5 were 328.3>105.1 and 328.3>188.1. The transitions used for MT-45 were 349.3>181.1 and 349.3>169.2. The retention times for acetyl fentanyl D5 internal standard and MT-45 were 1.72min and 2.26min. The calibration curve was 1-100ng/mL, with higher concentrations diluted to bring them within the linear range. Targeted analysis of the MT-45 in the case described above was measured at a concentration of 520ng/mL. The cause of death was determined to be acute opioid (MT-45) intoxication. Target analysis for etizolam in the blood also measured a concentration of 35ng/mL. No specificity or matrix effects experiments were performed due to the unique nature of the targeted analysis for uncommon analytes.

Synthetic Opiates, MT-45, Etizolam

K65 The Art of Embalming vs. the Science of Forensic Toxicology

Sonia Cuevas, BS, OCME, 520 First Avenue, New York, NY 10016; Wendy Santiago-Tirado, BS, OCME, 520 First Avenue, New York, NY 10016; and Marina Stajic, PhD, OCME, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will better understand the challenges unique to interpretation of toxicological findings in postmortem cases. Attendees will be provided with an overview of toxicology aspects of postmortem changes associated with the postmortem artifacts.

This presentation will impact the forensic science community by further delineating the interpretive aspects of toxicological findings in embalmed cases and the need for analysis of the embalming fluid whenever an unexpected analyte is detected to eliminate or confirm postmortem contamination.

Postmortem forensic toxicology is an important integral part of the medicolegal investigation of death. The complexity of postmortem toxicology testing and the nature of specimens submitted for analysis make the interpretation of forensic toxicology results a continuing challenge. In addition to evaluating laboratory methodologies for drug analyses, the condition of the body, drug characteristics, matrix, and site of specimen collection are among the factors that need to be considered in the proper interpretation of an autopsy specimen result. Chemical fixatives such as formalin or embalming fluids cause interference with toxicological analyses. Some funeral homes also add ethylene glycol and/or propylene glycol to the embalming fluid to increase the effectiveness of the arterial embalming process. Consequently, these substances added to commercially available embalming solutions are not included as components on material safety data sheets provided by the manufacturer.

The case involved an 81-year-old man who died at home under hospice care. His death was reported for cremation clearance with cause of death attributed to end stage renal disease due to diabetes mellitus. Following embalming and the wake, the family requested that an autopsy be performed based on their suspicion that the decedent was possibly poisoned with “antifreeze.” Ethylene glycol is used as a major component of antifreeze fluids. An oral dose of 100mL is believed to be fatal to most adults. Propylene glycol, a relatively non-toxic substance, is used extensively as a substitute for ethylene glycol in automotive antifreeze. Its pharmaceutical applications include use as a preservative, emollient, and vehicle for both oral and intravenous medications.

In addition to routine toxicological analysis, specimens were tested for the presence of ethylene glycol and propylene glycol. Analysis was performed using a gas chromatograph with a 5973 mass spectrometer equipped with a RTX-BAC1 column (30m x 0.32mm x 1.8µm film thickness). Acetonitrile was used as the protein precipitation solvent and 1,3-propanediol as the internal standard. The reporting limit was 50mg/L.

Ethylene glycol was not detected in any of the specimens. Results for propylene glycol were as follows: brain, 567mg/kg; liver, 122mg/kg; gastric content, 381mg/kg; vitreous humor, 432mg/L; and, urine, less than 100mg/L. Further investigation revealed the presence of propylene glycol in one of the embalming fluids used by the funeral home.

Specimens from an additional 27 embalmed cases were subsequently analyzed for the presence of ethylene glycol and propylene glycol. Ethylene glycol was detected in six cases, propylene glycol in 12 cases, and both were detected in three cases.

Propylene Glycol, Embalming Fluid, Postmortem Artifacts

K66 Case Study: A Suicide Death by Sotalol Overdose

*Autumn Massiello, PhD**, Sedgwick County Regional Forensic Science Center, 1109 N Minneapolis Street, Wichita, KS 67214; and *Jeffrey Walterscheid, PhD*, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054

After attending this presentation, attendees will understand the dual mechanistic actions of sotalol that make it a preferential treatment option for individuals with symptoms of cardiac arrhythmias, as well as the potentiation of its adverse effects in a fatal overdose.

This presentation impacts the forensic science community by detailing the investigative and toxicological analyses that assisted in resolving the first report of a suicide by sotalol in Harris County, TX.

With the capacity to function as both a beta-adrenoreceptor antagonist and potassium channel inhibitor, sotalol is the preferentially prescribed b-blocker for the treatment of ventricular tachycardia and ventricular fibrillation. As a b-blocker, sotalol is a non-selective competitor for binding sites on the b_1 and b_2 adrenergic receptors that regulate the production of cAMP, and, subsequently, intracellular levels of calcium that are required in generating electrical signals for muscle contraction, as well as generating the force for contraction; however, later studies have also established sotalol as an inhibitor of potassium ion channels, an action that has been demonstrated to cause a concomitant decrease in the efflux of potassium ions. In this manner, sotalol can further delay the generation of electrical signals for contraction and serve a dual therapeutic application for the correction for type III cardiac arrhythmias. Taken together, sotalol can function to decrease intracellular calcium concentrations while also inhibiting the efflux of potassium channels and these dual mechanistic actions can cause prolongation of both the PR and QT intervals that have been implicated in the treatment of rhythm disturbances of the heart and hypertension.

This study describes the case of a 61-year-old woman with a history of depression, who was found deceased in a secured and locked hotel room. A handwritten "last will and testament" were also found on the bed, near the decedent, as well as several prescription medications and loose pills. The decedent had a history of depression and prescription drug abuse, which, in combination with the scene description, indicated a likely suicide with toxicological relevance. Initial findings from the laboratory confirmed only modest amounts of nortriptyline, clonazepam, and tramadol consistent with the prescribed and therapeutic regimen for the decedent; however, these findings were inconsistent with the suicidal ideation described in the case details, thus prompting a re-evaluation of the blood specimen by Liquid Chromatography/Time-of-Flight/Mass Spectrometry (LC/TOF/MS) analysis. One advantage of LC/TOF/MS over other applications of chromatography with mass spectroscopy is the ability to screen, simultaneously, for a spectrum of drugs as comprehensive as the content of the drug library data. A review of the LC/TOF/MS results indicated an unidentified peak consistent with sotalol, suggesting its possible contribution in the cause of death for this case. Additional testing confirmed the presence of sotalol, with reported amounts of 38mg/L in blood and 83mg/L in the stomach contents. For comparison, the therapeutic target range of sotalol is 0.5-3mg/L in blood.

In conclusion, the acute poisoning potential of a combined b-blocker and potassium-channel inhibitor with an emphasis on the toxicological findings and an application for screening by LC/TOF/MS for the implication of sotalol in an intentional overdose death will be discussed. This case highlights a rare fatality since scant information exists on this subject. As sotalol gains widespread use, these events may become more prominent. The lessons learned from this presentation will raise awareness about the methods to identify sotalol, including interpretive support for postmortem toxicology consultations.

Sotalol, LC/TOF/MS, Overdose

K67 Manners of Death in Drug-Related Fatalities in Florida

Dayong Lee, PhD*, University of Florida, 4800 SW 35th Drive, Gainesville, FL 32608; Chris Delcher, PhD, University of Florida College of Medicine, 1329 SW 16th Street, Gainesville, FL 32608; Mildred M. Maldonado-Molina, PhD, University of Florida College of Medicine, 1329 SW 16th Street, Gainesville, FL 32608; Jon R. Thogmartin, MD, District Six ME, 10900 Ulmerton Road, Largo, FL 33778; and Bruce A. Goldberger, PhD, University of Florida College of Medicine, Dept of Pathology, 4800 SW 35th Drive, Gainesville, FL 32608

The goal of this presentation is to inform attendees about drug distribution and demographic characteristics associated with manner of death in drug-related fatalities in Florida so as to identify potential risk factors by drug or drug class, age, sex, and race with regard to manner of death.

This presentation will impact the forensic science community by helping to understand drug trends in potentially preventable deaths, identifying populations at greater risk of drug-related deaths, and hence, possibly leading to a more informed development of preventive measures of such deaths.

All drug-related deaths reported to the Florida Medical Examiners Commission through toxicology reports from 2001 to 2012 (n=92,596) were included. A death was considered “drug-related” if at least one drug was identified in the decedent, whether the drug contributed to the death or was merely present. For the purpose of this study, no distinction was made for drug-caused and drug-present deaths. Deaths related to the following drugs or drug groups were reported: amphetamines, benzodiazepines, cannabis, carisoprodol, cocaine, ethanol, γ -hydroxybutyric acid, heroin, inhalants, opioids, phencyclidine, and zolpidem. Manner of death was categorized into five groups: accidental, homicide, natural, suicide, and undetermined. Age cohorts included <18 years old, 18-34 years old, 35-54 years old, and ≥ 55 years old. Race was examined by African American, Hispanic, and White; other races were not included owing to <1% occurrence frequency. Relative risk refers to the category-specific probability of a particular manner of death compared to overall drug-related deaths, using Fisher’s Exact Test for significance testing.

Of all drug-related fatalities from 2001-2012, the most prevalent manner of death was accidental, comprising more than half (52.3%), followed by suicide (19.3%), natural (18.5%), and homicide (7.9%); 2.0% were undetermined. Expectedly, accidents contributed most frequently to drug-related deaths in all age groups (36.7% for ≥ 55 years old to 63.5% for 18-34 years old). Homicide was the second most common manner of death among the decedents under 35 years of age ($\geq 15.0\%$), whereas it was the least frequent for those ≥ 35 years of age ($\leq 6.0\%$). The reverse was true in natural deaths: 9.4%, 4.7%, 19.5%, and 32.6% of deaths of <18 years old, 18-34 years old, 35-54 years old, and ≥ 55 years old, respectively. Similar age disproportion was observed in suicides albeit to a lesser extent: 8.0%, 15.0%, 18.8%, and 26.0% deaths of <18 years old, 18-34 years old, 35-54 years old, and ≥ 55 years old, respectively. Males were significantly overrepresented in drug-related deaths on the whole; however, the proportion of mortality occurrence by manner of death was similar between females and males, except for homicide (5.5% of female deaths vs. 8.8% of male deaths). While accidental death was the most common drug-related death in African Americans (41.9%), Whites (53.5%), and Hispanics (62.3%), the race distribution of other deaths differed; the second most frequent manner of death was homicide for African Americans and Hispanics, but it was suicide for Whites. Proportions of natural deaths were more evenly distributed. Relative risk compared to overall drug-related deaths was >1.2 ($P<0.001$) in accidental deaths for 18-34 years of age; in homicides for <18-34 years of age, African Americans and Hispanics; and in natural deaths and suicides for ≥ 55 -years of age. Yearly proportional changes in the manners of death were generally marginal from 2001 to 2012 in the age, sex, and race groups, except a noticeable decrease in accidental deaths of <18-year-olds from 71.0% in 2001 to 44.7% in 2012. Drug distribution within the overall drug-related deaths showed frequent presence of ethanol, benzodiazepines, cannabis, cocaine, and opioids. Over 1.2 relative risk ($P<0.001$) was observed with alprazolam, carisoprodol, cocaine, heroin, methadone, and oxycodone for accidental death; amphetamines, cannabis, and cocaine for homicide; and diazepam and zolpidem for suicide. While the proportion of opioids in accidental deaths declined in 2011-2012, the opioids still remained as the most prevalent drug group and their proportions in other manners of death were not decreased during the study period.

A high relative risk was associated with age under 35 years for accidental death; age under 35 years, male, and African American/Hispanic for homicide; age ≥ 55 years for natural death; and age ≥ 55 years and White for suicide. Cannabis was significantly associated with homicide. Central Nervous System (CNS) stimulants including amphetamines and cocaine showed high relative risks for accidental death and homicide, whereas CNS depressants including benzodiazepines, carisoprodol, opioids, and zolpidem were more strongly associated with accidental death and/or suicide.

K68 A Survey of Human Performance and Postmortem Cases Involving Ketamine in San Francisco Between 1997 and 2013

Alexander C. San Nicolas, MSFS*, 300 Davey Glen Road, 3801, Belmont, CA 94002; and Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Terrace, 850 Bryant Street, San Francisco, CA 94103

After attending this presentation, participants will better understand the frequency of ketamine detection, as well as the concentration ranges of ketamine and its primary metabolite, norketamine, in Human Performance (HP) and Postmortem (PM) forensic toxicology cases in the City and County of San Francisco.

This presentation will impact the forensic science community by adding to the existing body of scientific knowledge of demographic characteristics of ketamine-positive PM cases, Driving Under the Influence (DUI) cases, and drug-facilitated crime cases and their toxicologic findings (including types of analyzed specimens), and ranges of concentrations typically encountered in such cases.

The Forensic Laboratory Division (FLD) of the Office of the Chief Medical Examiner (OCME) examines evidence from HP and PM cases on behalf of 14 law enforcement agencies operating within the City and County of San Francisco. For ketamine, commercially available Enzyme Linked Immunosorbent Assay (ELISA) kits are employed to screen blood (central/cardiac blood in PM cases; venous blood in HP cases) and/or urine received by the FLD. The ELISA blood and urine cutoffs for ketamine are 20ng/mL and 300ng/mL, respectively. Following a positive ELISA screen, confirmation and/or quantitation is performed in blood (peripheral blood in PM cases; a new aliquot of venous blood in HP cases) and/or a fresh aliquot of urine by Gas Chromatography/Mass Spectrometry (GC/MS) with a limit of quantitation of 0.01mg/L and 0.05mg/L for ketamine and norketamine, respectively. The assay uses tripeleamine as internal standard. The Retention Times, Target (underlined), and Qualifier ions for ketamine, norketamine and tripeleamine are presented in the table below.

Analyte	Rt (min)	Ions Monitored (m/z)
Norketamine	5.00	138, <u>166</u> , 168, 195
Ketamine	9.10	152, <u>180</u> , 182, 209
	9.96	58, <u>91</u> , 185, 197

In order to determine those HP and PM cases which involved ketamine and norketamine in San Francisco over the time period of interest, the in-house database was manually interrogated.

Seven HP cases were identified with confirmed ketamine and norketamine in blood, in which subjects averaged 31.7 years (range: 22-40 years), and were predominantly male (n=7; 71%), with a racial distribution of White (71%) and Asian (29%). The ketamine concentrations in these cases were (in mg/L): mean 0.30, median 0.18, range 0.05-0.65, standard deviation 0.24. The norketamine concentrations in these cases were (in mg/L): mean 0.61, median 0.29, range 0.00-1.52, standard deviation 0.56). In HP cases, ketamine was never encountered alone, but was always in the presence of other psychoactive drugs, most commonly ethanol (n=3), cannabis (n=3), benzodiazepines (n=2), and cocaethylene/benzoylecgonine (n=1).

In addition, 25 PM cases were identified involving ketamine. Twenty-one of these had the drug in the decedent's blood and 12 of the 21 also had ketamine confirmed in urine. Two PM cases only had ketamine confirmed in urine while one had ketamine confirmed in muscle, and one in liver. Decedents averaged 40.1 years (range: 19-64 years), were predominantly male (n=25, 88%), with a racial distribution of White (75%), Black (15%), White Hispanic (5%), and Asian (5%). The Manners of Death were: 17 Accidents, four Natural Deaths, two Undetermined, one Homicide, and one Suicide. The ketamine concentrations in these cases measured in peripheral blood (n=14) were: mean 0.91, median 0.29, range 0.01-3.71, standard deviation 1.24). Norketamine was only found in five case bloods (ranging from 0.05-0.16mg/L) and confirmed in four urines. Ketamine was encountered by itself in less than 10% of all PM cases in which it was detected. The most commonly encountered drugs with ketamine were amphetamines (n=8), cocaine (n=7), morphine/codeine (n=6), ethanol (n=4), methadone (n=3), oxycodone (n=3), GHB (n=3), diphenhydramine (n=3), and diazepam (n=3).

This study provides valuable information on the demographic distribution of ketamine users and decedents in the City and County of San Francisco and offers ketamine and norketamine reference blood concentrations. Comparison of the mean concentrations suggests that decedents with ketamine in their peripheral blood have concentrations three times higher than those measured in living individuals; however, comparison of the median values reduces the difference to approximately 60%, suggesting that ketamine blood concentrations should not be considered in isolation, but should instead be reviewed together with all other information available for Copyright 2015 by the AAFS. Unless stated otherwise, noncommercial *photocopying* of editorial published in this periodical is permitted by AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained by AAFS.

Toxicology Section - 2015

a better understanding of the totality of each case. Norketamine in living subjects was detected in concentrations almost twice that of ketamine in the same cases, suggesting a sufficient time interval for metabolism to occur. In postmortem cases, norketamine was rarely detected, suggesting that rapid deaths occurred shortly after exposure allowing little or no time for ketamine to be metabolized. The data presented in this study is useful to forensic toxicologists, pathologists, medical examiners, coroners, attorneys, and other law enforcement agents who need to understand and interpret ketamine and norketamine concentrations measured in HP and PM toxicologic specimens for the purpose of their medicolegal investigations.

K70 A Rare Case of Criminal Poisoning by Means of Butane Gas: N-Butane Quantification in Biological Fluids and Tissues

Jean Hiquet, MD, Forensic Unit, Place Amelie Raba Leon, Bordeaux, FRANCE; Florence Tovagliari, MD, Forensic Unit, Place Amelie Raba Leon, Bordeaux, FRANCE; Nathalie Grosleron-Gros, MD, Forensic Unit, Place Amelie Raba Leon, Bordeaux, FRANCE; Véronique Dumestre-Toulet, PharmD, Toxgen laboratory, 11 Rue du commandant Cousteau, Bordeaux, FRANCE; Jean-Michel Gaulier, PharmD, PhD, Biological and Forensic Toxicological Unit, 2 Avenue Martyin Luther King, Limoges F87042, FRANCE; and Sophie Gromb, JD, PhD, Forensic Department, CHU Pellegrin, BORDEAUX, Cedex 33076, FRANCE*

After attending this presentation, attendees will understand that the proof of a criminal poisoning with butane gas intoxication depends on the rapidity of collecting blood and tissues samples and butane determination using Headspace/Gas Chromatography-Mass Spectrometry (HS/GC/MS).

This presentation will impact the forensic science community by underlying the necessity of close collaboration between forensic physicians and toxicologists so that samples are analyzed as soon as possible after death. Moreover, forensic physicians will learn that this type of analysis must be carried out in a laboratory with an adequate method of detection and quantification by HS/GC/MS. Finally, this case broadens the literature concerning n-butane concentration in postmortem samples.

This study will present a rare case of criminal poisoning with n-butane as an example of the practical application of this necessary interdisciplinary communication and collaboration. It is recommended that medicolegal death investigators become familiar with the specificity of research of n-butane in postmortem samples.

There are some reports of fatal cases related after accidental or deliberate n-butane inhalation, but criminal poisoning with n-butane remains exceptional. N-butane determinations in biological samples can sometimes be of interest to confirm intentional or accidental fatal intoxications with this volatile aliphatic hydrocarbon.

This study reports the case of a 52-year-old woman found dead in a car next to her husband who was conscious, showed no sign of distress, and alleged an unsuccessful suicide pact. He explained that the couple had chosen to inhale n-butane together in their vehicle parked in the garage as the method of committing suicide. A gas bottle with an 8.5cm pipe was found in the car. Death examination at the scene revealed petechial haemorrhages to the upper eyelids and slight abrasions on the neck. An autopsy was requested. Before this was performed, the forensic physician contacted the toxicologist. Because of the volatile nature of n-butane, the toxicologist explained blood and tissues samples had to be extracted as soon as possible after the body was incised.

The autopsy showed a congestive aspect on the head, peri-ocular petechial hemorrhages, conjunctival hemorrhages, abrasions on the lips, and small semi-circular abrasions with bruises on the neck. The first step of internal examination consisted of cardiac blood sampling. Samples of blood, brain, lung, liver, and heart were removed 20h after the discovery of the body. Internal examination showed pulmonary and cerebral edema, congestion of the organs associated with bruises on the tongue and on the left side of the thyroid cartilage. No important injury was seen in the cervical area. The cause of death was noted as asphyxiation.

A large drug and toxic compound screening was performed on cardiac blood, brain, lungs, liver, and heart and a specific research for volatile substances was performed with HS/GC/MS. After having determined the presence of n-butane, quantitative determination was performed. Briefly, an external calibration (from 0.078 μ g to 3.9 μ g of n-butane) by means of volumetric dilutions from a supplied calibration gas mixture was achieved. A gas-tight sample lock syringe and a specific connecting device enabling direct sampling in the gas cartridge were used. Chromatographic separation was then performed using an RT-Q-Bond Column (30 m x 0.32 mm i. d.) and the detection of n-butane occurred in single ion monitoring mode: m/z 41 for quantitation; m/z 43 and 58 for qualification. In 1mL blood sample, the method is linear from 78 μ g/L Limit of Quantitation (LOQ) to 3,900 μ g/L. Precision was checked by inter-day CVs and associated relative bias (n=5), which were lower than 25%, and 20%, respectively. N-butane concentrations were 610 μ g/L (blood), 50ng/g (brain), 134ng/g (lungs), 285ng/g (liver), and 4,090ng/g (heart).

A rare criminal poisoning case of asphyxia associated with n-butane inhalation has been described in this study. Even if the exact time of death is unknown, due to close cooperation between the forensic physician and the toxicologist, rapid collection of blood and tissue samples during the autopsy and an adapted analytical method, the proof of intoxication as the cause of death was found. Collecting samples in properly sealed containers designated for volatile substances and analyzing the samples for the presence of volatiles solutions as soon as possible after collection is recommended.

N-Butane, Criminal Poisoning, HS/GC/MS

K71 Asphyxia Due to Inhalation of Hydrogen Gas

Dana Mike, BS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Anna Kelly, PhD, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand a unique case in which suicide by asphyxiation using hydrogen was suspected. The detection of hydrogen in postmortem specimens was performed using Headspace/Gas Chromatography/Thermal Conductivity Detection (HS/GC/TCD).

This presentation will impact the forensic science community by providing a method for the detection of hydrogen in postmortem specimens, allowing a toxicological confirmation for cause of death.

Suicide via asphyxia using inert gases, most commonly helium or nitrogen, has become more common in recent years. Asphyxiation under these conditions results from the inhalation of inert gas instead of oxygen; unconsciousness can occur in as little as one minute. For these kinds of cases, the typical signs of asphyxia include cerebral and pulmonary edema, congestion of internal organs, petechial hemorrhages, and frothy edema in the respiratory tract. These signs are sometimes present, although there are often no significant postmortem abnormalities.

Hydrogen is the most abundant element and is also the lightest element on the periodic table. It exists as a diatomic gas, H₂, at standard temperature and pressure. Hydrogen gas is used in a variety of different areas, including fossil fuel processing and ammonia production.

A 50-year-old man was found dead by his wife in his home office with a large blue recycling bag over his head with tubing coming from the bag and attached to a pressurized tank of hydrogen. The carbon monoxide alarm was going off in the house. He was a mechanical engineer for the National Aeronautics and Space Administration and had access to various gases and chemicals. His wife stated that the decedent often took pressurized tanks home and left them in his office.

Alcohol and drug screens, as well as carboxyhemoglobin analysis, performed on this case were negative. Postmortem specimens were analyzed for the presence of hydrogen using a method that had been developed originally for cases in which helium was used as an asphyxiant to commit suicide. At the time of autopsy, samples of lung, brain, blood, and fat were collected and sealed in 22mL headspace vials by the forensic pathologist. Each specimen was analyzed using HS/GC/TCD, with separation performed at 50oC (isothermal) on an HP-Molesieve column using argon as the carrier gas. This method is capable of separating several gases, including nitrogen, oxygen, hydrogen, and helium. The vials were incubated at 38oC for two minutes, then 100µL of headspace was removed from the vial and injected into the GC.

Hydrogen was found to be present in all samples analyzed. The Limit Of Detection (LOD) for this case was determined using the peak areas present in the negative controls; the average of these was 8.75×10^4 . Each of the samples analyzed had peak areas of an order of magnitude greater than the LOD. Additional assays were performed on cases in which hydrogen was not suspected to rule out presence in postmortem specimens. This method of analysis will not be useful in cases of moderate to advanced decomposition due to the number of gases produced during decomposition.

In conclusion, this analysis provides a method for detection of hydrogen that aids medical examiners in the determination of cause and manner of death. Additionally, these assays are easily conducted, both in specimen acquisition and toxicological analysis.

Hydrogen, Gas Chromatography, Postmortem

K72 Characterizations of AB-PINACA, AB-FUBINACA, and Metabolites Identified in Driving Under the Influence (DUI) and Postmortem Cases by Liquid Chromatography/Time-of-Flight Mass Spectrometry (LC/TOF/MS) and Liquid Chromatography With Tandem Mass Spectrometry (LC/MS/MS)

Michael Chen, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Jeffrey Walterscheid, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand the putative structural information of AB-FUBINACA and AB-PINACA metabolites in humans and their identification by mass spectroscopy.

This presentation will impact the forensic science community by raising awareness of a newly emerging synthetic cannabinoid category and the interpretation of toxicological results.

Following the previous wave of JWH Spice/K2 compounds, a new series of carboxamide-based synthetic cannabinoid receptor agonists with an indole or indazole motif have been identified. This new generation of synthetic cannabinoids, including but not limited to, AB-PINACA, ADB-PINACA, ADBICA, 5-fluoro-AB-PINACA, AB-FUBINACA and ADB-FUBINACA, were designated as Schedule I controlled substances in the United States since January 2014.

AB-FUBINACA was first synthesized by Pfizer® as a potent CB1 receptor modulator, with 10-fold greater affinity for the CB1 receptor ($K_i=0.9\text{nM}$) than that of JWH 018, for potential therapeutic use. AB-FUBINACA was found in illegal herbal products along with AB-PINACA in Japan in 2012. To date the biochemical, physiological, and toxicological properties of these synthetic cannabinoids in human have not been determined. The pharmacokinetics properties *in vitro* or *in vivo* via rat model have been reported by other laboratories. Here, synthetic cannabinoids and their metabolites were investigated by the analysis of DUI and postmortem casework samples.

Specimens were prepared by liquid-liquid extraction using 1:1 isopropanol/1-chlorobutane solvent mixture, followed by LC/TOF/MS screen in a water/methanol mobile phase system. The individual drugs were identified by a PCDL library with an identification criteria window of $\pm 15\text{ppm}$ mass error and ± 0.1 minute retention time of target analyte to yield scores greater than 55. The retro-analysis of LC/TOF/MS results revealed the presence of hydroxyl, dihydroxyl, and carboxylic adducts of AB-PINACA and ADB-PINACA, as well as hydroxyl modification to AB-FUBINACA, but without the observance of the carboxylic acid metabolite. The hydroxyl transformation was also found for other indazole-based synthetic cannabinoids.

The confirmation was later carried out by LC Triple Quad by the multiple reaction monitoring method, in which the parent compounds and their selected oxidized forms (i.e., ADB-PINACA-N-4-hydroxypentyl, ADB-PINACA-N-5-hydroxypentyl and ADB-PINACA pentanoic acid) were included. In consideration of ion interference, the isobaric and isomeric compounds were distinguished by HPLC separation. The metabolites were confirmed by the comparisons of retention times, fragment ions, and ion ratios from known standards.

By monitoring synthetic cannabinoids from the end of 2013 through 2014 in Harris County, frequent use of carboxamide-indazole-based cannabinoid receptors agonists was observed versus the fading, near absence of indole-based JWH compounds, except UR-144 and XLR11. Among them, AB-PINACA is the most commonly observed, followed by AB-FUBINACA and ADBICA.

Synthetic Cannabinoids, AB-PINACA, LC/TOF/MS

K73 Determination of Presence and Quantification of Ketamine, Norketamine, and Dehydronorketamine in Dosed and Buried Rat Remains at Different Stages of Decomposition

Cassandra L. Prickett, BS, Arcadia University, 450 S Easton Road, Glenside, PA 19038; Kimberlee S. Moran, MSc, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Laura M. Labay, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will understand the potential to detect and quantify ketamine in buried and decomposing remains using a three-step homogenization, Solid Phase Extraction (SPE), and a Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) method. Attendees will also become aware of the effects of postmortem interval and body parts on detection.

This presentation will impact the forensic science community by demonstrating the effects of burial on the distribution of drugs and enabling the toxicological analysis of organs in buried and decomposing bodies.

To date, several studies have been carried out to identify drugs in decomposed/decomposing remains, yet few studies on buried remains have been published. Studies on buried remains have tested only skeletal tissue in controlled testing environments; no other tissue matrices sampled from buried remains have been tested.

The goal of this study was to determine if ketamine could be detected in soft tissues collected from buried rats, and if so, in what quantity compared to the dosage given. Rats were dosed at three levels: 20mg/kg (n=13); 30mg/kg (n=13); and, 40mg/kg (n=13). Control/untreated animals were also tested (n=4). Injections were made daily for ten days. Rats were then euthanized, two sets (n=21) at an hour after the last injection and one set (n=15) ten days after the last injection. One rat at each dosage (0mg/kg, 20mg/kg, 30mg/kg, and 40mg/kg) was analyzed without burial for comparison. The remaining rats were buried and then exhumed at different stages of decomposition (77, 188, 293, 793, and 3,104 Accumulated Degree Days (ADDs) after burial) to determine the effect of burial length and stage of decomposition on drug distribution and detection. The rats were dissected and samples were taken from the brain, heart, and liver. When those were no longer discernible, the general viscera in the areas of the brain, heart, and liver were sampled. At 77 and 188 ADDs, organs were still intact. By 293 ADDs, some organs had started to liquefy and by 793 ADDs, most organs were liquefied. Brain samples were most affected by decomposition and were not available from some animals in the later stages of the research. Samples were weighed, diluted with saline (1:1 for brain and liver, 1:2 for heart), and homogenized using a Biotage® Bead Ruptor 24. The samples were then centrifuged and the drugs were extracted from the supernatant using SPE. The amount of drug present, ketamine, norketamine, and dehydronorketamine, was quantified in soft tissues using LC/MS/MS with ketamine-D4 as the internal standard.

As expected, ketamine, norketamine, and dehydronorketamine were not detected in the tissue samples from the rats that were euthanized ten days after the last dose. Ketamine and its metabolites were detected in samples from the dosed rats that were not buried and exhibited a dose-response relationship. The drugs were also detected in most of the buried rat tissue samples, with higher concentrations in the higher dosed rats. Where discernable tissue was available, liver concentrations were found to be higher than the heart and brain concentrations.

Ketamine, Buried Remains, LC/MS/MS

K74 Analytical Method Development and Robustness Evaluation for Gas Chromatographic Analysis of Piperazine Designer Drugs

Kathleen K. Luo, BS*, 107 Whitmore Lab, University Park, PA 16802; and Frank Dorman, PhD, 107 Whitmore Labs, University Park, PA 16802

After attending this presentation, attendees will have a better understanding of an analytical screening method for piperazine designer drugs by Gas Chromatography (GC) coupled to both Mass Spectrometry (MS), Flame Ionization Detector (FID), and Nitrogen Phosphorus Detector (NPD).

This presentation will impact the forensic science community by demonstrating thorough development of a GC analytical method for the detection of piperazine designer drugs. This method would provide crime laboratories with a more robust GC analytical method for screening piperazine-derived drugs and improve overall accuracy of base-type drug analysis.

Synthetic designer drugs are among the most commonly abused drugs on the market.¹ Designer drugs are compounds that are synthesized to simulate the structures and effects of illegal drugs of abuse. To evade the risk of being charged with using drugs, there has been a trend toward consumption of designer drugs instead of the illegal drugs of abuse. Synthetic piperazine-derived drugs are one of the many emerging types of synthetic designer drugs on the market. Piperazine-derived drugs are not only being consumed directly, but also being added to multiple different street drugs. Developing a method to analyze and detect piperazine compounds (i.e., BZP and TFMPP) will aid the screening for emerging synthetic piperazine drugs.

The objective of this research is to optimize the conditions and parameters for a method using simultaneous GC/MS/FID/NPD in order to screen for and detect piperazine-derived compounds. An NPD has higher sensitivity than an FID and a single quadruple MS system, but it is less specific than MS. Due to the amine group of the piperazines, NPD was used to quantitate, providing a lower level of detection than the MS. Additionally, the NPD is likely to exhibit less instrumental drift than the MS, making it a potentially better choice for quantification. In addition, piperazines may exhibit chemical reactivity in the GC sample pathway. A series of commonly used piperazine drugs were evaluated as part of a study to investigate the chemical reactivity. During the course of this research, the impact of the deactivation chemistry of the inlets and columns was evaluated, with results ranging from poor to excellent. Based on chromatographic probes, including tailing factor, the best combination of column and inlet liner was chosen.

The rapidly changing synthetic piperazine market and regulation of these compounds has created a need for developing a more reliable screening technique, which allows crime laboratories to handle various kinds of piperazine-derived compounds. This method increased the accuracy of the analysis by comparing the chemical reactivity in the GC pathway and increased the sensitivity and selectivity by coupling both MS and NPD. This complete investigation of the chromatographic variables as directed to both native piperazines, and their relevant metabolites, in both recreational drug samples and human urine will allow for a consolidated analytical methodology that is more efficient in a commercial laboratory.

Chart 1 Column Comparison Based on Average Tailing Factor Using a Restek-Based Deactivated Gooseneck Inlet Liner

Column	Avg. Tailing Factor
Rtx-5MS	1.728±0.127
Rxi-5SilMS	2.395±0.164
Rtx-5 Amine	2.021±0.062
Rtx-35	1.892±0.106
Rxi-35 SilMS	2.094±0.27
Rtx-1301	2.611±0.13
Rxi-1301Sil	1.949±0.132

Chart 2 Gooseneck Inlet Liner Comparison Based on Average Tailing Factor Using a Rxi-35 SilMS Column

Liner	Avg. Tailing Factor
Base Deactivated	2.09±0.273
Siltek Deactivated	1.99±0.137

Toxicology Section - 2015

IP Deactivated	2.163±0.148
Sky Liner	2.652±0.215
Ultra Inert Liners	2.01±0.083

K75 Comparison of Solid Phase Extraction (SPE) and Supported Liquid Extraction (SLE) Columns for the Extraction of 23 Novel Psychoactive Substances From Blood and Urine

Lorna A. Nisbet, MSc, 310 S Easton Road, Apt B311, Glenside, PA 19038; and Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will be able to compare SLE and SPE columns and identify the correct choice for optimum recovery of cathinones and NBOMes from a variety of biological matrices.

This presentation will impact the forensic science community by increasing awareness of extraction options for the determination of novel psychoactive substances in forensic toxicological samples.

SLE columns are now commercially available and pose an alternative to SPE. SLE has commercial benefits over SPE in that it does not produce the same amount of solvent waste and can be carried out in fewer steps depending on the type of SPE column being compared.

Recently, there has been an influx of new synthetic substances to the recreational drug market with laboratories struggling to keep pace in this “cat and mouse” game. To improve detection rates, it is vital that laboratories are using the optimum sample preparation technique to allow maximum analyte recovery and sample throughput.

The goal of this research was to determine whether SLE+ columns can be used as a possible alternative sample extraction method for the detection of synthetic cathinones and NBOMes and to evaluate which clean-up method produces the maximum recovery across a range of 25 drugs.

Blank methanol, urine and blood samples (1mL) were spiked with 100µL of 10µg/mL solutions of various different NPS's (methiopropamine, flephedrone, mephedrone, MDPV, 2-DPMP, butylone, ethylone, naphyrone, 5-APB, 6-APB, 3-MeO-PCE, methoxetamine, benzedrone, 25B-NBOMe, 25C-NBOMe, 25D-NBOMe, 25E-NBOMe, 25H-NBOMe, 25I-NBOMe, Mescaline-NBOMe, 25N-NBOMe, 25P-NBOMe, 25T2-NBOMe, 25T4-NBOMe, and 25T7-NBOMe). Urine samples were pH adjusted to 10.8 using 1% ammonium hydroxide (NH₄OH). To each sample prepared for SPE, 1mL of 0.1M phosphate buffer (pH6) was added before centrifugation for ten minutes at 4,000rpm. UCT's ZDSAU020 columns were conditioned using methanol, deionized water, and phosphate buffer before loading samples. Columns were washed using deionized water, 0.1M acetic acid, and methanol. Samples were eluted using methylene chloride; iso-propanol; NH₄OH (78:20:2). For SLE, following pH adjustment with 1% ammonium hydroxide, samples were loaded directly to Biotage's® SLE+ columns. The sample was held on the column for five minutes before being eluted with 2x4mL of ethyl acetate. Internal standards (mephedrone-D₃, methylone-D₃, ethylone-D₃, MDPV-D₈, and 25I-NBOMe-D₃) were added to the collection tubes prior to elution. Post-extraction, samples were evaporated using a stream of nitrogen, derivatized using 50µL of PFPA:ethyl acetate at 70oC for 40 minutes, before being evaporated again and reconstituted in 100µL of ethyl acetate. Samples were analyzed by GC/MS with the SLE and SPE results being compared directly to unextracted methanolic standards at the same concentration.

All drugs were successfully extracted from each matrix using both SPE and SLE columns. For blood, SLE+ columns provided a higher recovery rate of drug than the SPE columns, with an average increase of 10% (recovery ranging from -47% to 80%). SPE-extracted urine samples more efficiently providing an average of 5% increase in recovery rates (recovery ranging from 47% to 92%).

In conclusion, when analyzing blood samples, SLE+ should be used whereas SPE is more efficient for the extraction of these analytes from urine.

SPE, SLE, Novel Psychoactive Substances

K76 Application of Time-of-Flight/Mass Spectrometry (TOF/MS) With Three Different Fragmentation Modes to the Toxicological Screening of Urine Samples Collected From an Electronic Dance Music (EDM) Population

Helen Piper, BS, 3550 Bartram Road, #31, Willow Grove, PA 19190; Alexander L. Maggitti III, BS, 3701 Welsh Road, Willow Grove, PA 19090; Jared Castellani, BS, 150 Ridge Pike, #108-A, Lafayette Hill, PA 19444; Francis X. Diamond, BS, 3701 Welsh Road, Willow Grove, PA 19090; Matthew M. McMullin, MS, 3701 Welsh Road, Willow Grove, PA 19090; and Barry K. Logan, PhD, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090*

After attending this presentation, attendees will better understand the pattern of use of Novel Psychoactive Substances (NPS) drugs for a population at risk of abuse of the newest compounds on the illicit market. Attendees will also have a better understanding of current trends describing the compounds that are most prevalent and those emerging on the scene.

This presentation will impact the forensic science community by providing information that can be used for harm reduction, education, and increased certainty of detection following the use of the newest compounds on the market. Manufacturers of standards, law enforcement, emergency medical care professionals, and those involved with user education and drug treatment programs can all utilize this information.

A variety of analytical methodologies including immunoassay (**Enzyme-Linked Immuno-Sorbent Assay (ELISA)**), Gas Chromatography Mass Spectrometry (GC/MS), and Liquid Chromatography/Mass Spectrometry (LC/MS) screening were applied to samples collected from attendees at an electronic dance music festival where there was a high level of self-reported use of NPS drugs. Samples were additionally analyzed using three different modes of Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS).

The range of NPS drugs is constantly changing and many similar compounds, analogs, and isobaric compounds are being sold and distributed; the ability to distinguish between closely related compounds is critical for forensic toxicology testing. Considering High Resolution Accurate Mass Spectrometry (HRAMS) data of both the parent compound and fragment ions provides more specific structural information that can be used for identification of drugs and their metabolites, eliminating some of the false positives caused by artifacts, minor metabolites, degradation products, drug analogs, and isomers in complex forensic specimens. Incorrect presumptive identifications from a screening method may lead to unnecessary confirmatory testing and/or an excess of candidate compounds requiring thorough manual data evaluation for a simple presumptive screening identification.

An Agilent® 1290 HPLC/6530 Q/TOF mass spectrometer with Jet Stream® Technology was used to analyze samples; LC conditions were kept constant while evaluating three different ionization modes. The modes were conventional Quadrupole Time-of-Flight (Q-TOF) and two All-Ions ionization modes: Collision-Induced Dissociation in the Source (CIDS) and Collision-Induced Dissociation in the Collision Cell (CIDCC). The conventional Q-TOF mode uses targeted MS/MS analysis, while the CIDS and CIDCC All-Ions modes provide fragmentation data through the use of alternating fragmentor voltages in the source or collision energies in the collision cell, respectively. CIDS mode also allows for the acquisition of Q-TOF-like data on a conventional TOF mass spectrometer. The elution profiles of each of the ions, parents, and fragments are correlated for use in compound identification.

Samples were analyzed against a database/library containing approximately 140 emerging drugs of abuse or NPS. Each entry was complete with molecular formula, providing the accurate mass up to four decimal places, and the retention time; MS/MS spectra was available for some compounds. Presumptive identifications were made based on retention time, mass accuracy, isotope ratios and spacing, abundance thresholds, the presence of fragment ions, and the comparison of ion ratios to the database reference entry.

Of the samples analyzed, the most common compounds identified and confirmed consisted of methylone, alpha-PVP, MDA, MDMA, amphetamine, and ethylone. O-desmethyltramadol has not been confirmed but was commonly found by all three modes and the additional screening methods. Some of the other compounds that have been confirmed in at least one sample were fluoroamphetamine, buprenorphine, butylone, dextromethorphan, methamphetamine, norketamine, and psilocin. Of the more prevalent compounds, ethylone was the most commonly missed compound by all three methods, with the Q-TOF not identifying it in any of the samples for which

Toxicology Section - 2015

it was confirmed. MDMA was another relatively common false negative missed mostly by the Q-TOF mode; however, there was no Q-TOF reference spectra for MDMA in the database. Amphetamine and alpha-PVP yielded few false negatives. In addition to the false negatives observed, the Q-TOF mode produced the most false positive findings. Generally, the All Ions methods performed better than the Q-TOF method in terms of false positive and false negative findings.

Novel Psychoactive Substances, Time-of-Flight (TOF), Toxicological Screening

K77 Optimization of Extraction Parameters Using IMCSzyme™ β -Glucuronidase for Opiate Analysis of Various Toxicological Matrices

Nancy A. Kedzierski, MS*, Orange County Crime Laboratory, 320 N Flower Street, Santa Ana, CA 92703; and Danielle C. Mata, MS, 320 N Flower Street, Santa Ana, CA 92703

After attending this presentation, attendees will be able to evaluate the optimal parameters of IMCSzyme™ β -glucuronidase and its use for opiate analysis in whole blood. Attendees will also be able to evaluate the use of those parameters in the analysis of opiates in various toxicological matrices (Antemortem (AM) blood and Postmortem (PM) blood, urine, and liver.)

This presentation will impact the forensic science community by offering analysts information on an enzyme that could shorten the analysis required for total opiate analysis.

Samples of whole porcine blood were spiked with various concentrations, representing the lower and upper ends of the calibration standards used, with morphine- β -glucuronide, morphine-6 β -glucuronide, codeine-6 β -glucuronide, hydromorphone-3 β -glucuronide, and oxycodone-3 β -glucuronide. Samples (1mL) were hydrolyzed at 55°C using a 1:1 mixture of IMCSzyme™ β -glucuronidase:pH 6.8 phosphate buffer. The enzyme volume was optimized by examining the recovery using 100 μ L or 200 μ L IMCSzyme™ β -glucuronidase (52,000 U stock). The hydrolysis time was also optimized by testing 30-minute or 1-hour hydrolysis time with the different enzyme amounts. After hydrolysis was complete, deuterated internal standard (100 μ L) was added to each sample and standard. Samples were then sonicated, centrifuged, and the supernatant was derivitized using 100 μ L of 5% methoxylamine and cleaned up via solid phase extraction. Samples were then dried, derivitized again using 100 μ L of a 1:1 mixture of propionic anhydride and pyridine, then analyzed via gas chromatography/mass spectrometer with selective ion monitoring.

Once optimal parameters were established, those parameters were used to analyze the IMCSzyme™ β -glucuronidase efficiency in various toxicological matrices commonly tested for opiates. All matrices were tested to obtain results for the free opiate content and the total opiate content using IMCSzyme™ β -glucuronidase and the currently used *H. pomatia* β -glucuronidase.

It was determined that 100 μ L of IMCSzyme™ β -glucuronidase with 30-minute hydrolysis time produced sufficient hydrolysis in the spiked porcine samples. The enzyme produced comparable or better hydrolysis efficiency with all five glucuronide forms studied than the currently used *H. pomatia* β -glucuronidase in the initial optimization experiments done on porcine blood. Based on the matrix studies, the IMCSzyme™ β -glucuronidase returned comparable or better hydrolysis efficiency in AM blood, PM blood, and urine than the *H. pomatia* β -glucuronidase; however, IMCSzyme™ β -glucuronidase appeared to underperform in liver samples, with codeine-6 β -glucuronide proving to be the most difficult glucuronide to hydrolyze in all matrices.

Based on manufacturer recommendations, a 2:3 ratio of IMCSzyme™ β -glucuronidase: pH 7.4 phosphate buffer, with 30-minute hydrolysis time at 55°C was used for hydrolysis in urine to increase overall extraction efficiency, especially for codeine-6 β -glucuronide.

Future work will be conducted to attempt to increase hydrolysis efficiency in liver samples. Due to the consistency of the sample matrix, longer hydrolysis times may be tested to allow the enzyme more time to effectively hydrolyze the opiates. Other tests will consist of sonicating the samples prior to hydrolysis or agitating the samples during the hydrolysis step.

Toxicology, Opiate, Glucuronide

Toxicology Section - 2015

K78 Postmortem Pediatric Toxicology

Robert A. Middleberg, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; Nikolas P. Lemos, PhD, OCME, Forensic Lab Division, Hall of Justice, N Terrace, 850 Bryant Street, San Francisco, CA 94103; Erik D. Christensen, MD, State of UT MEO, 48 N Mario Capecchi Drive, Salt Lake City, UT 84113; James R. Gill, MD*, OCME, 11 Shuttle Road, Farmington, CT 06032; Ellen Moffatt, MD*, City & County of San Francisco, OME, 850 Bryant Street, San Francisco, CA 94103; and Marina Stajic, PhD*, OCME, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will gain an appreciation for the challenges unique to toxicological findings in postmortem pediatric cases. Attendees will learn interpretive guidelines for pediatric cases involving forensic toxicology in both a general and a case-specific sense.

This presentation will impact the forensic science community by further delineating the interpretive aspects of toxicological findings in the pediatric population.

In this 15th Annual Special Session within the Toxicology section, pediatric cases involving toxicological findings are discussed. As a relative dearth of interpretive information involving toxicological findings in the pediatric population exists, this session is a forum to help elucidate and clarify such issues. The format is a short case presentation including pharmacokinetic data and other relevant ancillary information followed by audience participation to provide interpretive clarity around the case-specific impact of the toxicological findings. This session, attended by various sections of the Academy, allows for various perspectives of case issues that lead to integrative consensus, or differing opinions, as to cause of death in children.

Four cases will be presented that highlight the difficulty in assessing the role of toxicants in each case.

James Gill will be reviewing a case from his vast experience as a forensic pathologist. Dr. Gill has a particular interest in toxicological issues and his presentation will highlight the pathologist's view on toxicological findings and mitigating factors in the interpretation of findings in this population.

Erik Christensen will discuss a case of an 8-month-old female found unresponsive face down in her bed in a blanket. The scene was indicative of potential toxicological involvement, yet the substance ultimately detected in the child, trazodone, was not one of the substances obvious at the scene. Trazodone, an atypically-structured antidepressant is not a drug typically prescribed for an 8-month-old child. The potential role of trazodone in the death of this child will be discussed in respect to a final diagnosis.

Marina Stajic will discuss a high-profile case involving the brutal murder of an 8-year-old boy who was dismembered. The toxicological findings in the case will be reviewed with the potential role of detected agents in the cause of death of the child versus being "red-herring" findings.

Ellen Moffat will present a case of the sudden death of a child and a finding of isopropyl alcohol in postmortem samples. The genesis of the isopropyl alcohol in this child and the potential role of the substance in the fatal outcome will be described. Additionally, the potential sources of postmortem isopropyl alcohol findings in the absence of known ingestion will be described.

The case studies presented reflect current-day findings in medicolegal investigations of childhood deaths. In years past, discussions of these type cases have been educational and demonstrative of the issues in this special population. Only through these continued case studies and audience participation can there be shared perspectives on the meaning of the toxicological findings.

Pediatric, Postmortem, Toxicology A Title Sample

LW1 Asperger's Disorder: Does It Make Someone Violent?

Katherine Ramsland, PhD, DeSales University, 2755 Station Avenue, Center Valley, PA 18034*

After attending this presentation, attendees will know what the current research reveals about a potential link between Asperger's disorder and explosive violence.

This presentation will impact the forensic science community by illustrating the importance of knowing research results before making legal decisions that accept or reject causal links between Asperger's disorder and violent acts.

Elliott Rodgers went on a "day of retribution" rampage in May 2014 in Santa Barbara, CA. He killed six people and injured thirteen before shooting himself. He wanted to punish "you girls" for rejecting him. The media focused on his prior diagnosis of Asperger's disorder.

Adam Lanza killed his mother on December 14, 2012, before going to Sandy Hook Elementary School in Newtown, CT, to gun down six staff members and twenty students. He then shot himself, leaving no explanation. His computer was destroyed, but inside his room were memoirs about Asperger's disorder. There were also reports that Lanza had once received this diagnosis. Assumptions were quickly made in the national media that Lanza's aggression was Asperger's-related violence.

Knowledge about Asperger's disorder (part of Autism Spectrum Disorder (ASD)) has developed significantly since it was named in 1944, but confusion persists, especially regarding its relationship to extreme antisocial behavior. When violent incidents occur that superficially appear to have a link with ASD, there is a risk of making quick assumptions that unfairly stigmatize those who present with this disorder.¹ Yet if research designs have failed to identify a link that actually exists, then threat assessment personnel and attorneys who represent clients with this disorder need this information. However, the research thus far includes small or unrepresentative samples, a lack of targeted research on those with the Asperger's variant of ASD, a lack of specificity in the type of violence studied (as opposed to general aggression), and a lack of community sampling.²

There exist few cases of stranger-based destructive violence, and for those in which ASD might be a factor, other factors are also evident that may play an equal or more significant role.³ Comorbid with ASD, Adam Lanza had severe Obsessive-Compulsive Disorder (OCD), hypersensitivity to touch, a fixation on mass murder, and bouts of depression and paranoia. In most of the ASD cases in which violence has occurred, they generally had a reactive component rather than being planned and prepared.⁴ However, the high-profile violence committed by individuals like Rodgers and Lanza has generated notions that Asperger's is a variant of psychopathy. Some reports imply that, like psychopaths, people with ASD have no empathy and thus no emotional incentive to be prosocial. Hence, they're prone to becoming violent. Such statements rely on erroneous perceptions of ASD.

With the increased media attention on ASD during violent incidents, assumptions are made about its role in violence that can adversely influence treatment of such individuals in the criminal justice system.

LW2 The Gunshot Residue Evidence of *The People of the State of California v. Robert Blake, the Actor*

Bryan R. Burnett, MS*, Meixa Tech, PO Box 844, Cardiff, CA 92007-0844

After attending this presentation, attendees will be aware of the details of the Gunshot Residue (GSR) evidence in the trial of *The People of the State of California v. Robert Blake*.

This presentation will impact the forensic science community by raising awareness of how GSR evidence can be misused in a case.

The shooting of Ms. Bonny Bakley occurred on May 4, 2001, at approximately 9:30 p.m. while she was sitting in the front passenger side of Mr. Blake's 1991 Dodge® Stealth®. Ms. Bakley was waiting for her husband, Robert Blake, to return from the restaurant where they had just dined. Mr. Blake had allegedly returned to the restaurant to retrieve his forgotten .38 caliber revolver. There were no witnesses to the shooting.

The GSR expert in the case of *The People of the State of California v. Robert Blake* was retained by attorney Thomas Mesereau several weeks prior to his withdrawing from the case and his retention by Michael Jackson. Attorney Gerald Schwartzbach was hired by Mr. Blake and the GSR expert's role was as a consultant throughout the case. Schwartzbach had already found and retained a GSR expert by the time he discovered the previous GSR expert's involvement. He did, however, send the discovery to the previous GSR expert. The previous GSR expert's report was submitted to the defense prior to trial, but was ignored.

A criminalist of the Los Angeles County Department of the Coroner performed the majority of the GSR analyses for the prosecution. Even though the jury likely came to an appropriate decision, this case should never have gone to trial with its flawed evidence.

The issues were: (1) the submitted spectra of the alleged consistent GSR from Mr. Blake's hands did not match the testified composition of the particles. It appears Blake's GSR data was mixed with another case; (2) Blake was carrying a .38 caliber revolver the night of the shooting; (3) upon the shooting of Bakley in the passenger seat of the car, Blake sat in the driver's side seat allegedly not realizing she had been shot. He reported touching her; (4) Blake was taken to the police station without hand protection and his hands were sampled for GSR at the police station; (5) the clothing Blake was apparently wearing the night of the shooting was collected by a police officer the following morning after Blake was returned to his home via a police car; and, (6) Blake's clothing was stored in an open box in the trunk of a police car for 48 hours. The clothing was handled by a police officer without hand protection.

Blake's Hand Samples: For issue 1, even though the defense was informed of the mismatch prior to trial, the GSR expert was not impeached in cross nor was this information presented to the jury when the defense got the case. For issues 2, 3, and 4, even if particles were identified as characteristic of GSR on these samplers, it would be meaningless. Contamination from any of these sources cannot be dismissed.

Blake's Clothing Analyses: For issues 3, 4, 5, and 6, even if particles were identified as characteristic of GSR on these samplers, it would be meaningless. Contamination from any of these sources cannot be dismissed.

An Issue of the Chain of Evidence: For issue 5, the chain of evidence was broken. There was no way of verifying the clothing picked up at Blake's home by the police officer was the same as that worn by Blake when the shooting occurred.

The Defense: The defense GSR expert erred by not considering any of the above issues. In addition, the pistol used in this shooting was twice fired with ammunition different from that used in the shooting. The shooter's hands were immediately sampled and a total analysis of the two samplers by scanning electron microscopy was performed. The defense expert's invalid assumptions will be discussed. This work performed by the defense should never have been allowed to be presented to the trier of fact.

Robert Blake, Gunshot Residue, Junk Science

LW3 The Exhumation and Identification of the Remains of St. Marianne Cope of Molokai

Vincent J. Sava, MA, JPAC-CIL, 310 Worcester Avenue, Bldg 45, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will appreciate St. Marianne Cope of Molokai as a historical figure and the role forensic science played in her canonization as a saint in the Catholic Church.

This presentation will impact the forensic science community by showing applications of forensic anthropology to a case involving the remains of a historical figure.

Health and disease influence the histories and cultures of any region. The legacy of leprosy in Hawaii is one of horrific and heartbreaking suffering, unimaginable hardships as well as inspirational and heroic sacrifice, all leading to the sainthood of two individuals. One of these saints, Marianne Cope, is the subject of this presentation.

A hundred years after Western contact, introduced diseases had scythed the Native Hawaiian population from 300,000 to 50,000 people. Leprosy afflicted up to 5% of the Native Hawaiians by the 1870s. To halt its spread, in 1866 Hawaiian authorities exiled several hundred patients to a “colony” on the isolated Kalaupapa peninsula on the island of Molokai. The peninsula is a geographic prison. Ravaged patients were unable to climb the 2,000-foot cliffs comprising the colony’s southern border or swim the rough shark-infested seas ringing its other three sides.

The early days of the colony were grim. Law and order were absent; there was inadequate shelter, little food, filthy water, scant medical care, and no hope. Half of the 800 patients arriving between 1866 and 1873 died within two years. Father Damien DeVeuster, a Belgian priest, arrived in 1873 and worked tirelessly to establish a quality of life for his patients.

A contemporary of Father Damien was Mother Marianne Cope, a Franciscan nun. Mother Marianne was already an experienced and respected health-care provider in New York when she responded to Hawaii’s pleas for assistance. She was ahead of her time, recognized for initiating the first patients’ bill of rights, as the founder of the hospice movement in the United States, and as an early adherent to Lister’s germ theory. Arriving in Honolulu in 1883, she worked tirelessly to improve the care of leprosy patients throughout Hawaii, founding hospitals and homes for children orphaned by leprosy.

Mother Marianne arrived at Kalaupapa in 1888 to care for the patients, including Father Damien who was dying of leprosy. Upon his death in April 1889, she assumed full responsibility for the care and welfare of the Kalaupapa patients. By this time, conditions had improved to the point where providing adequate and state-of-the-art health care for the patients was the predominate issue facing the colony. Originally planning on staying only six months in Hawaii, Mother Marianne remained in the service of her patients until her death from natural causes in 1918.

Mother Marianne was buried on Kalaupapa. As a candidate for sainthood, Mother Marianne’s resting place had to be more accessible to the faithful. Consequently, a decision was made to move her remains from her remote grave to a shrine in her hometown of Syracuse, NY. Additionally, her sainthood cause requested that her remains be identified using forensic techniques. Planning and preparation took nine months, including researching that the grave in question was undoubtedly Mother Marianne’s.

Using forensic recovery methods, Mother Marianne was exhumed from her grave in late January 2005. She was taken to a makeshift laboratory at a nearby convent and circumstantially identified. The lines of evidence used toward the identification were: (1) verification of the grave through historical research; (2) the archaeological findings relevant to the grave and the remains; (3) the biological profile of the remains; and, (4) the material evidence or artifacts recovered from the grave.

Mother Marianne was returned to Syracuse soon after her exhumation. She was canonized a saint by Pope Benedict on October 21, 2012. In July 2014, Mother Marianne returned to Hawaii. Her remains are now enshrined in Our Lady of Peace Cathedral in Honolulu. Leprosy continues to be a problem in Hawaii. On average, 200 new cases are diagnosed in the Hawaiian islands each year. Even though segregation laws were abolished in 1969, about a dozen leprosy patients still reside on Kalaupapa. All are over the age of 65 years old.

Leprosy, Human Remains, Religious Relics

LW4 Romance and Reality: Horses and Experimentation

Jennie Meade, JD, MLS, 716 20th Street, NW, Washington, DC 20052*

After attending this presentation, attendees will understand: (1) how horses are used for experimentation; (2) that the categories and goals of experimentation upon horses vary widely; (3) the effects of different types of experiments on the subject horse's welfare; (4) the necessity for performing certain types of experiments on horses; and, (5) to what extent United States law protects subject horses during experimentation.

This presentation will impact the forensic science community by focusing attention on the little-known uses of horses in experimentation. By describing the types of experiments horses are subjected to, the effects on the subject horses, and legal oversight of the process, this presentation will serve to heighten awareness of the issues associated with the important and growing equine segment of animal experimentation.

The romance and lore of the horse persist in obscuring hard realities associated with the lives of certain horses, both historically and in modern times. Finding that horses are used for medical and other experimentation, along with rats and monkeys, comes as a surprise to those whose comprehension of equines ends with the horse as noble helpmate and sporting partner. Horse experimentation may be on the rise; recent European Union statistics reveal an increase in the use of equines in animal experimentation, while at the same time logging a decrease both in the numbers of animal experiments and in the overall numbers of animals used in experiments.

In the 19th century, horses routinely were used in experiments involving vivisection, and this practice continues today, alongside less invasive experimentation. Horses are used in biological studies, research and development of human medicines, testing of veterinary vaccines, disease diagnosis, toxicology, nutritional studies, and behavioral studies. Certain experimentation is driven by potential human medical benefit and other research is directed toward improving knowledge of the horse. Some horse experimentation has been identified as not only unnecessary but painful for the equine experiment subjects. Certain other experiments are not only painless but may be enjoyable for the horse. "Horse experimentation" covers a spectrum of activities, goals, and results.

Legal regulation of animal experimentation has a long history, beginning in England in the 19th century. True to its tradition of animal welfare activism, today the United Kingdom remains at the legislative vanguard of protecting animal experimentation subjects. United States law, on the other hand, is developing and to date remains less comprehensive than its United Kingdom counterpart, with many lacunae. In areas where United States legal coverage is adequate, inadequate enforcement can render the laws ineffective.

Horses, Experimentation, Law

LW5 Once Upon . . . Forensic Sciences

Matteo Borrini, PhD*, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Camilla Borrini, MSc, Medtronic, via del mattone 17/a, La Spezia, AE 19131, ITALY

After attending this presentation, attendees will understand how it is possible to communicate and teach forensic sciences to younger generations of students without favoring television trends that highlight morbid and macabre aspects but rather by emphasizing the role of the science and forensic scientists.

This presentation will impact the forensic science community by suggesting a new method of teaching forensic sciences based on a clear communication, not the simplistic language of fairy tales.

The CSI effect is a phenomenon according to which the expectations of jurors and the general public for forensic evidence are affected by the popularization of forensic sciences in the so called “reality-based” crime-fiction television drama. On the other side, the proliferation of television programs and movies that involve the role of charming forensic scientists can also create a new and different CSI effect, which would be the extreme interest of young children and teenagers in forensic sciences. This in turn would lead to an increased demand for undergraduate and graduate programs in this area of study. Unfortunately, the fiction cannot present the real contribution that each discipline can give to the investigations, creating wrong expectations in young students who are planning their education. In addition, the tendency of these television dramas is to emphasize the gory aspects of murder investigation and present the bloody scene with amusement.

Against the trend of TV series, this study proposes the use of Disney’s® fairy tales as teaching aids to focus the attention on the role of forensic scientists. The very nature of these fairy tales is completely non-macabre; therefore, it is suitable for young students. In addition, they are appropriate for an adult public which has grown up with these stories. For these reasons, this presentation’s purpose is to shift the emphasis from cruel and meaningless scenes to technical aspects of the investigation presented in an easy-to-understand language.

Starting from the first Disney® animated feature film, *Snow White and the Seven Dwarfs*® (1937), it is possible to show how the Evil Queen could be able to detect that the huntsman returned with a pig heart instead of Snow White’s by conducting a histological test. This very popular film can also teach the meticulous method and caution required in crime scene investigation: Snow White, in fact, misinterpreted the identity of the owners of the Dwarfs’ untidy cottage when she first inspected it.

At the same time, the search for the young princess by Maleficent, in *Sleeping Beauty*® (1959), is a good example of how forensic art could be applied in the aging process of missing children. In addition, in this tale the poison on the spike of the spinning wheel is useful to explain the potential of toxicological analysis.

Other aspects of forensic sciences and investigation can be presented by using other Disney® films, such as *Bianca and Bernie*® (1977), for geographic profiling and the search for kidnapped children. *Lady and the Tramp’s*® (1955) characters provide an insight into the topic of tracking dogs. Still related to the canine world, *One Hundred and One Dalmatians*® (1961) serves as an example of wildlife forensics.

In addition, *Beauty and the Beast*® (1991) offers support to present two important concepts in forensic science: (1) the “fruit of the poisonous tree”; and, (2) the goal of justice. In this animated musical film, the arrogant hunter, Gaston, steals a spellbound mirror from Belle and uses its magic power to spy on the Beast, misconstruing his attitude and using the images to make him appear evil. This movie also serves as a good teaching support to explain the importance of a correct collection and interpretation of the evidence, according to the most recent guidelines of the scientific community. At the end of the film, Gaston tries to incite the mob against the Beast who he wants to have killed. The happy ending demonstrates the fallacies of self-made justice and asserts the actual, primary goals of forensic science and the judiciary system, which are to provide impartial justice based on objective evidence.

This study will describe how it is possible to teach forensic sciences in a fascinating and attractive way by going against the grain of fashion dictated by macabre and morbid television series, converting Disney’s® motto, “Where Dreams Come True™” to “AAFS, where forensics come true.”

Forensic Science, Teaching, Education

LW6 Death in Police Custody: Negligence or Body Packing and Self Administration?

David M. Benjamin, PhD*, 77 Florence Street, Ste 107N, Chestnut Hill, MA 02467-1918

The goals of this presentation are to: (1) review the metabolism of heroin; (2) recognize how the route of the administration of heroin leads to differences in the formation of 6-monoacetylmorphine (6-MAM); and, (3) examine how the onset of the signs of heroin overdose can lead to determining the approximate time at which heroin was used.

This presentation will impact the forensic science community by explaining how the onset of a toxic drug effect may provide information about the time of use of the toxic agent.

Police officers arrested Mr. X for possession of illicit drugs with intent to distribute. At the time of the arrest, police officers alleged that they saw Mr. X swallow several marble-sized bags of contraband containing an unidentified white powder. Police officers believed this powder to be cocaine but no field tests or laboratory tests were ever performed on the samples in question.

Mr. X was taken into custody and assigned to a single cell which was equipped with video monitoring. In addition, police officers were supposed to come by Mr. X's cell and monitor him for safety every 15 minutes. A review of the monitoring checklist indicated that monitoring visits were not conducted according to the 15-minute schedule.

On the day of Mr. X's death, Mr. X appeared in good health between 8:00 a.m.-9:00 a.m., when breakfast was served. However, when police officers came by to serve lunch between 11:00 a.m. and noon, Mr. X was found to be unresponsive with a great deal of blood-tinged, frothy, white fluid emanating from his mouth and nose.

His family filed a wrongful death civil suit against the police department and the city that employed the police officers, alleging negligence and failure to adequately monitor Mr. X's condition while in their care. A forensic expert on the toxicity of heroin was retained on behalf of the police department and the municipality in question.

The metabolism of heroin involves several steps and differs depending upon the route of administration. Following Intranasal (IN), Intramuscular (IM), or Intravenous (IV) administration of heroin, heroin is almost immediately hydrolyzed to 6-MAM in the blood and then travels to the liver where the second acetyl group is removed, liberating morphine. 6-MAM and morphine are the active ingredients which actually manifest the psychopharmacological effects of heroin in the brain. In contrast to IN, IM, or IV administration, orally administered heroin is rapidly converted to morphine in the stomach and virtually no 6-MAM is formed or found in blood or urine.

Findings at Autopsy: At autopsy, three small bags (less than one inch in diameter) of white powder were removed from the decedent's stomach. The contents of the bags were never analyzed, but the presence of Benzoylcegonine (BE) and 6-MAM in the decedent's urine indicated that both cocaine and heroin were present to some extent. The codeine is an impurity extracted from the opium poppy during the processing of the morphine into heroin.

Major laboratory toxicology findings (specimen: postmortem fluoridated femoral blood):

- Free codeine: 56 ng/ml; Free morphine: 987 ng/ml.

In urine:

- Cocaine metabolite, BE: 666 ng/ml.
- 6-MAM: present — less than 40 ng/ml.
- Free morphine: greater than 2,000 ng/ml; free codeine: greater than 2,000 ng/ml.

Plaintiff's Theory of the Case: Plaintiffs alleged that the decedent died as a result of swallowing several bags of heroin and that the heroin slowly leached out of the bags over several days, accumulating to a toxic level, ultimately causing the decedent to experience respiratory depression and pulmonary edema, which led to his death.

Defendant's Theory of the Case: Mr. X appeared in good health during the first few days of his incarceration and never showed any signs of drug ingestion until he was found in pulmonary edema around noontime on the day of his death. Following a heroin overdose, pulmonary edema occurs either immediately or within four hours of the overdose. Since Mr. X appeared healthy at breakfast time (8:00 a.m.-9:00 a.m.), the heroin must have been ingested between 8:00 a.m. and noon. Because 6-MAM was detected in urine at autopsy, the heroin must have been ingested by a route other than absorption from the stomach, implying that the heroin was probably "body packed" into the facility and self-administered by "snorting."

Heroin, 6-Monoacetyl Morphine, Pulmonary Edema

LW7 **The Investigation Into the Identification and Death of Ukrainian Journalist Georgiy Gongadze: An International Case of Revolution, High Politics, and Toxic Consequences**

William C. Rodriguez III, PhD, OCME, 900 W Baltimore Street, Baltimore, MD 21201*

After attending this presentation, attendees will gain a heightened perspective and awareness of the political and social ramifications involved in conducting international forensic investigations in which the case outcome can result in serious consequences to others as well as a danger to oneself.

This presentation will impact the forensic science community by serving as a strong reminder of the importance of forensic science to society and that it should be utilized in a truthful, careful, and unbiased manner to ensure that justice is served.

This case involves the murder of Ukrainian journalist Georgiy Gongadze, who was kidnaped and murdered in the Taraschanskyi district outside of Kiev, Ukraine, in September of 2000. Gongadze was a well-known Ukrainian journalist and co-founder of the news website *Ukryinska Pravda*. Much of Gongadze's journalistic work involved exposing the massive corruption within the political establishment of the Ukraine, with his primary target of contention being Ukraine President, Lenoid Kuchma. It was reported that during the presidential election in 1999, Kuchma's headquarters made contact with Gongadze, informing him that he had been blacklisted and was to be dealt with after the election. In early 2000, while visiting New York with other Ukrainian journalists, Gongadze warned of "the strangulation of the freedom of speech and information in our state."

Two months later, after Gongadze's disappearance, his badly decomposed and decapitated body was discovered in a forest approximately 43 miles outside of Kiev. Initial examination of the remains revealed they had been doused in dioxin as well as gasoline, which failed to burn properly. In a bizarre turn of events, the headless corpse was confiscated by police and hidden away in a remote barn. The remains later resurfaced in a morgue in Kiev as the result of investigations by other journalists. Several months passed without any official word concerning the remains.

In early 2001, the United States government became concerned regarding the outcry by international journalists and government opposition leaders concerning the Gongadze case and the increasingly authoritarian government of President Kuchma. As a result of political and public pressures against the Kuchma regime, an official request was made to the United States by the Ukrainian government for forensic assistance in the case. The United States responded by sending a small forensic team from the Federal Bureau of Investigation (FBI) and the Armed Forces Institute of Pathology to the Ukraine in March of 2001. During this visit, the United States team was plagued by many obstacles that appear to have been purposely initiated in order to prevent the examination of the remains. As the result of a stalemate, the United States team left the Ukraine but returned a month later to conduct the investigation as originally planned. During this same period, a close bodyguard of President Kuchma requested political asylum in the United States after making public previous secret recordings of the President and top cabinet members giving orders to have Gongadze dispatched.

As a result of the second visitation, the remains in the Kiev morgue were positively identified as those of Georgiy Gongadze via radiographic and DNA comparisons. Even though the second attempt to examine the remains of Gongadze was successful, it was not without incident. At the completion of the examination, and just prior to the joint writing of the report findings, a team member became seriously ill, requiring medical attention, resulting in extreme concern by the United States Embassy staff. A rapid return to the United States by this team member, followed by a medical examination, including toxicology, revealed the presence of high levels of mercury. The high mercury levels which are presumed to have resulted in the illness was considered to be the result of poisoning that occurred via ingestion of water from a bottle that had been tampered with. Other cases of poisoning within the former Soviet Union of individuals who had posed a political threat occurred in 2004 with the poisoning of the pro-western Ukrainian President Viktor Yushchenko by dioxin and in 2006 of the former Russian Komitet Gosudarstvennoy Bezopasnosti (KGB) Agent Alexander Litvinenko, who defected to England and died as the result of lethal polonium 210 poisoning. The obstacles encountered will be presented in order to prepare others as to the political, social, and personal hazards that can be encountered in similar investigations.

Assassination, Human Identification, Poisonings

Financial Disclosure - 2015

As an accredited provider of Continuing Medical Education, the American Academy of Forensic Sciences requires speakers to disclose any real or apparent conflict of interest they may have related to the content of their presentation(s). The existence of commercial or financial interest of authors related to the subject matter of their presentation(s) should not be construed as implying bias or decreasing the value of their presentation(s); however, disclosure should help participants form their own judgments. AAFS and the Program Committee review the submissions to ensure that the content is educational and not a commercial presentation for companies and their products. Participants may notify AAFS by email (abstracts@aaafs.org) should any presentation be considered solely a commercial endorsement presentation. Notification should include presentation number/ID (e.g., BS10, E100, W30) and speaker name.

If an author failed to provide complete disclosure of the discussion of commercial products, a relationship with the manufacturer including employee/ employer relationship, sources of support for the research project, and/or the discussion of unlabeled or unapproved uses of pharmaceuticals/medical devices, the presentation was not accepted. Authors are required to disclose at the beginning of each presentation any information disclosed and listed below. Copies of the executed disclosure forms are kept on file in the AAFS Office.

Presenting Author Index- 2015

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2014 Annual Scientific Meeting. The reference table below assists you in finding the section in which the

presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A	Anthropology	J	Questioned Documents
B	Criminalistics	K	Toxicology
C	Digital & Multimedia Sciences	LW	Last Word Society
D	Engineering Sciences	BS	Breakfast Seminar
E	General	ES	Evening Session
F	Jurisprudence	L	Luncheon
G	Odontology	S	Special Session
H	Pathology/Biology	W	Workshop
I	Psychiatry & Behavioral Science
